The strength of the troops in Hong Kong and the Straits Settlements was 2266. Of these 1217 were at Hong Kong and 1049 in the Straits Settlements. Among the former the admissions were 1169, the deaths 8·21, and the mean sick 47·28 per 1000; among the latter, 792, 2·86, and 38·64. The discharges by invaliding from the whole force were 6·18 per 1000. At Hong Kong there were 9 cases of enteric fever, with 2 deaths; the cause of these could not be discovered, "but at the time of the occurrence there were cases of enteric fever in the city, where the drainage is very defective." Malarial fevers were very prevalent, the admissions amounting to 499 per 1000. This was due to the disturbance of the soil in preparing the sites for the new forts. In the Straits Settlements there were 6 cases of enteric fever with 1 death, 3 at Tanglin, and 3 including the fatal case at Penang; 5 of them were in men recently arrived, and who were believed to have brought the disease with them. The admissions by malarial fever were only 63·8 as against 409 8 per 1000 in the preceding year. This great improvement has been attributed partly to the drainage of the rifle range at Tanglin, and partly to an exceptionally dry year; the troops also were composed of seasoned men who had just arrived from South Africa. The admissions by all forms of venereal disease in the command were 189 and the non-effectives 13·38 per 1000; they were slightly more prevalent in the Straits Settlements than in Hong Kong. The water at Hong Kong requires to be boiled and filtered; but "it is hoped that in a few months the supply will be furnished from the new waterworks at Tytain." The Asiatic troops, 220 strong, had 1532 admissions, 22·72 deaths, 31·50 mean sick, and 9 09 invalided per 1000 of strength. The principal cause of admission was malarial fever.

The average strength of the British troops in Egypt was 5272, of whom 4827 were in Lower Egypt, and 445 formed the frontier force at Assouan. From the former the admissions were 1129, the deaths 14·09, and the mean sick 71·56 per 1000; from the latter they were 831, 26 96, and 44·45. The invalids discharged the service were 17·27 per 1000 from the whole force. These ratios are all considerably under those of the preceding year. There were 26 cases and 4 deaths of small-pox, which is stated to be very prevalent among the civil population. There were 157 admissions and 37 deaths from enteric fever, being in the ratio of 29·8 and 7·02 per 1000 of strength. The death-rate by it was only one-third as high as in 1886. The admissions were chiefly at the citadel, Cairo, amounting to 122 with 30 deaths; there were 20 cases with 5 deaths at Assouan.

Digitized by Google

The greater prevalence at Cairo was attributed to "the local insanitary conditions, the unusually high Nile and its rapid fall." The cases at Assouan occurred in the first five months; the immunity afterwards "was probably due to the men sent to Assouan being specially selected, over twenty-two years of age, and relieved frequently." The decrease at the other stations is attributed to the bulk of the force consisting of seasoned troops, quartered in good barracks, more settled, and better fed. Of 119 cases of ague, 104 occurred at Alexandria; there were 7 cases of remittent fever, all at Assouan. The admissions from all forms of venereal disease were 134, and the constantly non-effective from it 11·24 per 1000—a slight increase upon the preceding year. The drinking water at Assouan was always boiled and filtered, and during the period of high Nile was also treated with alum to clear it.

METROPOLITAN HOSPITAL SUNDAY FUND.

A MEETING of the Council of the Metropolitan Hospital Sunday Fund was held at the Mansion House on Monday to consider the annual general report of the Committee of Distribution. The Right Hon. the Lord Mayor, president and treasurer, occupied the chair, and Sir S. H. Waterlow acted as vice-chairman.

Mr. HENRY N. CUSTANCE, the secretary, having read the notice convening the meeting and minutes of the preceding meeting, the committee's report was taken as read. It recommended the payment of awards to 161 institutions, being three more than last year, and an increase of fifty-six since the first awards were made in 1873. The total amount available for distribution, after allowing sufficient for liabilities and the usual current expenses, was £40,746. Of this total, £31,481 5*s.* was now recommended to 111 hospitals and 50 dispensaries. Five per cent. of the total collected—viz., £2000—was set apart to purchase surgical appliances in monthly proportions during the ensuing year. The committee recommended that all payments to the fund after this date be carried to the credit of next year's fund. In compliance with an order of the Council, and for the special use of its members, tables of statistics had been prepared as usual, showing an analysis of the number of beds in hospitals, the cost of patients both at hospitals and dispensaries, the proportionate expense of management, &c., and copies were sent to every member of the Council. The number of deputations, representing committees of various hospitals, invited to confer with the committee, and to offer explanations on matters of apparently unsatisfactory character, was only nine this year as compared with eleven in 1888. Four of these deputations attended, and in two cases the committee regretted to report that, after these interviews, they were unable to recommend any award. Five institutions sent replies, but did not attend. The application from one dispensary was withdrawn. Two institutions which had been less than three years established, and hence could not comply with Law IV. by furnishing balance-sheets for three years, had to be refused. One application from a nursing institution, being neither hospital nor dispensary, could not be entertained; and two from other institutions came too late.

Particulars of the awards were given in an appendix to the report. The awards to the twenty-two hospitals described as "general" were as follows:—Charing-cross, £989 11*s.* 8*d.*; French, £208 6*s.* 8*d.*; German, £677 1*s.* 8*d.*; Great Northern Central, £312 10*s.*; Guy's, £208 6*s.* 8*d.*; Italian, £72 18*s.* 4*d.*; King's College, £1406 5*s.*; London, £3333 6*s.* 8*d.*; Middlesex, £2031 5*s.*; University College, £1302 1*s.* 8*d.*; Westminster, £1093 15*s.*; Metropolitan, £260 8*s.* 4*d.*; Miller Hospital and Royal Kent Dispensary, £281 5*s.*; North-West London, £322 18*s.* 4*d.*; Poplar, £218 15*s.*; Royal Free, £958 6*s.* 8*d.*; St. George's, £1614 11*s.* 8*d*; St. Mary's, £1875; Seamen's, £677 1*s.* 8*d.*; Tottenham Training Hospital, £281 5*s.*; West London, £520 16*s.* 8*d.*; and SS. John and Elizabeth, £125. The remainder was distributed amongst 5 chest hospitals, 12 children's hospitals, 3 lying-in hospitals, 6 hospitals for women, 27 other special hospitals, 20 convalescent hospitals, 11 cottage hospitals, 7 institutions, and 50 dispensaries.

Sir SYDNEY WATERLOW, in moving that the report of the Committee of Distribution for 1889 be approved, and that the several awards recommended be paid, congratulated the Lord Mayor and everyone present on the fact that the Sunday collection this year had been larger than in any preceding year. The sum received up to the present time was £41,107, being considerably more than the total received last year; and, as three months had yet to intervene before the subscription-list for this year was closed, there could scarcely be a doubt that they would receive £700 or £800 more. Practically, there had been no dissatisfaction expressed on the part of those who had made application for help out of this fund. He congratulated the Council and the public generally on the fact that the accounts of the various hospitals were kept in a much better and more uniform manner than heretofore. He believed that the testing of one set of accounts by comparison with others had been of almost as great a benefit to the hospitals and dispensaries of the metropolis as the moneys which were contributed from the Sunday Fund. They had been much more carefully and economically administered. The Council had not this year received any large legacies, but he hoped the time was not far distant when persons of abundant wealth would come to the conclusion that they could not do better than assist the Hospital Sunday Fund, the Council of which had the fullest means of discriminating between the merits and needs of the hospitals and cognate institutions, and were the best almoners of the fund.

Mr. H. COSMO BONSOR, M.P., seconded the motion, and remarked that as regarded the way in which the awards had been made the committee were practically unanimous. The motion was agreed to.

The cordial thanks of the Council were voted to the Chairman and the other members of the committee for the labour and care they had bestowed in the preparation of the awards, and for the efficient report of their proceedings; to Sir Andrew Clark, Bart., M.D., LL.D., for the very able address delivered by him at the Mansion House meeting of June 19th, and also to the Right Rev. the Lord Bishop of Derry, and to other speakers; to the editors of newspapers who had pleaded the needs of hospitals and advocated the cause of this fund with a view to increasing this year's collection, and specially to Mr. Thomas Wakley, the Editor of THE LANCET, who had gratuitously prepared and issued to clergymen and ministers of religion special Supplements giving valuable statistics and general information; and to the Right Hon. James Whitehead, who, as president and treasurer of this fund, had lost no opportunity in devoting his attention and valuable time to raise the present year's fund above the record of past years, and the Council desired to congratulate his lordship upon his success. The movers and seconders of the foregoing votes of thanks were Dr. J. G. Glover, Rev. C. J. Ridgway, Sir Risdon Bennett, Dr. Charles J. Hare, Mr. C. Macnamara, Rev. R. R. Bristow, Mr. A. L. Cohen, and Dr. Morison.

The LORD MAYOR thanked the Council for the cordiality with which they had received the resolution in his favour. It was, he said, a great pleasure to him to be associated with this fund. It was well known that he was taking a very deep interest in all that was connected with the welfare of hospitals within the metropolitan area; and it might be known to some of them that he had initiated a new scheme in connexion with the Hospital Saturday Fund, which would not in any way interfere—he had been careful to observe that—with the action or the usefulness of the Hospital Sunday Fund. That movement had so far had the greatest success, and there was every probability that through his initiation the Saturday Fund would be more than doubled in the first year, and he thought he should not be going too far if he were to prognosticate that within the next three years it would be increased by at least fivefold. The system of penny-a-week collections in workshops, factories, and warehouses would work automatically. As the population increased there would be an increased demand upon the hospitals, but there would also be an increase in the number of those who by this scheme would be able to contribute towards their support. It was highly gratifying to him that during his year of office as Lord Mayor the record had this year been beaten so far as the contributions towards the hospital funds were concerned. It was rather a singular fact that this year there was not a single movement of any kind with which the Mansion House was connected, having for its object and aim the collection of funds, where the record had not been beaten. In every instance where he had had the honour of presiding at any public dinner, or at

Digitized by Google

any gathering where there was a collection on behalf of the institution, the amount received had exceeded the highest ever previously collected. He attributed that to a great extent to what he hoped and believed was a great improvement in the mercantile prosperity of the country.

The proceedings then terminated.

THE ROYAL COLLEGE OF PHYSICIANS.

THE adjourned meeting of the Comitia was held on the 30th ult., Sir Andrew Clark, Bart., President, in the chair. Dr. C. Meymott Tidy was elected an Examiner in Chemistry.

Considerable discussion arose over the report of the Leprosy Committee with reference to the recommendations of the Father Damien Committee, based on the proposals of H.R.H. the Prince of Wales. These recommendations were in effect: 1. To erect a memorial statue of Father Damien in Kalawao. 2. To form a fund to be devoted to the medical care and treatment of indigent British lepers in the United Kingdom; the application of the fund to be in the hands of three trustees, to be appointed by the Royal College of Physicians, the Royal College of Surgeons, and the General Committee of the "Father Damien Memorial Fund" respectively. Also to endow two studentships tenable for three years; one student to make the United Kingdom and the remainder of Europe his field of investigation, and the other to go abroad to study the disease in China, the colonies, and elsewhere. 3. To beg the Prince of Wales to invite the Viceroy of India to appoint an auxiliary committee with regard to the investigation into and treatment of leprosy in India; and that a Commission be appointed for not less than one year, consisting of three members, one to be named by the Royal College of Physicians, one by the Royal College of Surgeons, and one by the General Committee of the "Father Damien Memorial Fund," to go out to India for investigation, and that the Indian Committee be requested to add two members to this Commission. It was also, *inter alia*, recommended that a standing committee of not less than six persons, nominated by the bodies above named, should prepare memoranda for the guidance of the above-mentioned students and the Indian Commission. The report of the Leprosy Committee of the College, stating that it was undesirable to set apart a special ward for lepers in any hospital of the United Kingdom, and approving of the foundation of studentships and the appointment of a Commission (for a period of not less than two years, and with authority to visit any country or district of the British Empire), was, after considerable discussion and some modification of the original draft, adopted in preference to an amendment moved by Sir H. Pitman, which simply stated the readiness of the College to co-operate with the Father Damien Memorial Committee. It was suggested by the College that the various nominations made on behalf of the Father Damien Memorial Committee should be in the hands of the executive committee of that body.

The report of the University for London Committee was then received. It referred to the report of the Royal Commission, especially in regard to its recommendations for the reconstitution of a Medical Faculty in the University of London, and, in conclusion, pointed out the following as the chief points to be considered by the College:—1. The retention of the present power of the College to grant qualifications to practise. 2. The adequate representation of the Royal Colleges upon the governing bodies of any reconstituted university. 3. The conditions upon which the curricula and examinations for the qualifications of the Royal Colleges shall be accepted for the pass degree of a future London University. 4. Extension or modification of the present curricula of the Royal Colleges. After some discussion the committee was reappointed, with the addition of the names of Dr. N. Moore and Dr. Coupland, to consider the subject, especially in reference to the position of the College in the matter.

The quarterly report of the Finance Committee was received, as were also the annual reports of the Library Committee and of the Curators of the Museum.

A report of the Committee on the Extension of the Examination Hall Buildings was received. It stated that, in consequence of the injunction obtained at the instance of Messrs. Greenfield and Cracknall, it had been agreed not to carry the east wing of the building above the top of the second floor. The total amount of the costs incurred in the late action was £731 3*s.* 5*d.*, whilst the reduction in the builders' contracts, in consequence of the modifications in plans, amounted to £943 1*s.* 3*d.* The amended estimates for the erection of the building were £24,899 8*s.* 9*d.* In accordance with the suggestion of its members, the committee was reappointed to supervise the building operations.

THE PARIS UNIVERSAL EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT.)

The Forthcoming International Congress of Hygiene.—The Congress on the Help of the Wounded in War.

ON Sunday, Aug. 4th, at the Grand Amphitheatre of the Faculty of Medicine, and under the presidency of the Minister of the Interior, the International Congress of Hygiene and Demography will, with due solemnity, hold its inaugural sitting. It will be remembered that, though at the last Congress, held two years ago at Vienna, it was decided that the next should take place in London in 1891, that distant date was selected especially so as to permit an intermediary gathering at Paris during the Universal Exhibition. Though the present Congress does not partake of the same official character as the great Congress of Vienna and the future Congress of London, nevertheless several Governments will be officially represented. These are the Governments of Belgium, Brazil, Bolivia, Denmark, Egypt, Luxembourg, Monaco, Salvador, Spain, Roumania, Mexico, Turkey, the Argentine Republic, Paraguay, and Hawai. All the French sanitary societies, administrations, central and provincial, and many foreign administrations, send representatives. There will not be far short of 600 members, representing about twenty-five nationalities. The Congress is to meet at 9 A.M. and 2 P.M. each day, excepting Wednesday, Aug. 7th, when, by special train, the members will be conveyed to Rheims, a distance of 172 kilometres from Paris. At Rheims carriages will take the excursionists to the sewage farms, and after visiting the works the members will be entertained at lunch in the Château des Maretz. On returning to Rheims, the celebrated cathedral and equally celebrated champaign caves will be visited. Then the Congress is to be entertained by the Municipality at the Town Hall, and finally a special train is to bring the entire company back to Paris by 10 P.M. On the Monday evening the Congress will be received at the Ministry of Public Instruction, and on Tuesday by Dr. Brouardel, President of the Congress and Dean of the Faculty of Medicine. On Thursday evening the Congress will be entertained by the Paris Municipality at the Hôtel de Ville. On Friday evening the Congress will hold a banquet on the platform of the Eiffel tower. On the Saturday there is to be a reception given by the Minister of the Interior, and on Sunday, Aug. 11th, a visit to the Paris sewers and an excursion to the sewage farm of Gennevillier, conducted by M. Bechmann, chief engineer of the town of Paris. Ladies accompanying members of the Congress are especially invited to all these excursions and entertainments, and it will be seen that the programme is very complete. It is only to be regretted that in Paris, as in Vienna, there are not likely to be many English representatives. Professor Corfield, Mr. Shirley Murphy, Dr. Alfred Carpenter, Dr. C. Drysdale, and Mr. Adolphe Smith are among the English members of the Congress, and it is to be hoped that at the last moment many more will put in an appearance so as to participate in the great work of sanitary propaganda achieved by these Congresses. The Congress will divide into eight sections, to treat the following subjects:—Section 1: The hygiene of childhood, milk-supply, overwork in schools, &c. Section 2: Town and rural sanitation, construction of dwellings, ventilation, overcrowding, &c. Section 3: The germ theory applied to hygiene, infectious fevers, &c. Section 4: Industrial and professional hygiene, work of children in factories, unwholesome industries, &c. Section 5: International hygiene and sanitary police. Section 6: Food adulteration; water-supply; filtering processes. Section 7: Demography; sanitary statistics. Section 8: Cremation. This latter section

Digitized by Google

will in a measure constitute a separate congress of itself, and will be presided over by the President of the International Commission on Cremation. On each of the eight subjects printed reports are to be placed in the hands of the members of the Congress to serve as a basis of discussion. The reports for Section 3 and Section 7 are already in circulation. Such are the principal details concerning this important international meeting. It will be seen that the French authorities have spared no pains to provide agreeable and instructive entertainment for those who respond to their invitation, that the subjects to be discussed are most important, that the Governments of newer civilisations (such as the South American Republics) are anxious to gain every possible information, and that therefore the English sanitary reformers who have so often led in the van of progress, should be present in large numbers on this occasion. It is not too late to give notice of an intention to take part in the proceedings of the Congress. The entrance fee is twenty francs, and communications should be sent at once to the secretary of the International Congress of Hygiene at the Faculté de Médecine, Paris. All who are concerned in hygiene, as medical men, engineers, architects, inspectors, administrators, municipal councillors, &c., will be welcomed.

It is unfortunate that space does not admit of the full descriptions of all the Congresses that are now meeting in Paris. The International Congress for the Assistance of the Wounded in Time of War, for instance, gave rise to some very important debates. The question of antiseptic dressing, the mobilisation of the ambulance services, and the best means of teaching quickly how to tender the first necessary help on the field of battle were all fully investigated. M. le Dr. Riaut naturally took the lead in many of these discussions, but he was ably supported by MM. Romberg, Felix, John Furley, &c. The latter insisted on the care taken in England to educate women in ambulance work. Dr. Schneider read an important paper on the salubrity of the battlefield, how best to bury the dead without infecting the neighbouring residents, and without running the risk of burying those who were still alive. Among other suggestions, he urged that soldiers should wear round their necks or about their clothing a medal by which they could be identified. This would save much time. Burying parties need only remove the medal, and thus avoid all the trouble of identification. The promptness of burials contributed very materially to the salubrity of the battlefield. The Congress spent a considerable time visiting the exhibits on the Esplanade of the Invalides, notably the Tollet ambulances and the installations of the Société des Femmes de France. Dr. Renault also rendered good service by insisting on the absolute necessity of maintaining in the ambulance service the strictest neutrality during active warfare. The necessity of such neutrality, though very emphatically laid down by the Geneva Convention of 1863, was not sufficiently understood.

MALCOLM MORRIS INDEMNITY FUND.

THE following additional subscriptions to the above fund have been received :—

The costs amount to £480. Subscriptions may be sent to Mr. G. P. Field, 34, Wimpole-street; or to Dr. Sidney Phillips, 21, Upper Berkeley-street.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5471 births and 3850 deaths were registered during the week ending July 27th. The annual rate of mortality in these towns, which had been 21·5 and 21·0 per 1000 in the preceding two weeks, was again 21·0 last week. During the first four weeks of the current quarter the death-rate in these towns averaged 20·3 per 1000, and was 0·2 above the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 10·7 in Huddersfield, 12·2 in Derby, 14 6 in Brighton, 16·4 in Bristol, and 16·5 in Oldham. The rates in the other towns ranged upwards to 26·3 in Liverpool, 27·2 in Sunderland, 28·0 in Plymouth, and 48·6 in Preston. The deaths referred to the principal zymotic diseases in these towns, which had steadily increased in the previous five weeks from 400 to 1018, declined again last week to 999; they included 682 from diarrhœa, 91 from measles, 71 from whooping-cough, 67 from diphtheria, 57 from scarlet fever, 31 from "fever" (principally enteric), and not one from small-pox. These zymotic diseases caused the lowest death-rates last week in Wolverhampton and Huddersfield, and the highest rates in Salford, Plymouth, and Preston. The greatest mortality from diarrhœa occurred in Sheffield, Salford, Birmingham, Sunderland, Derby, Leeds, Leicester, and Preston; from measles in Halifax, Leeds, Hull, and Preston; from whooping-cough in Oldham, Preston, Bradford, and Birkenhead; from scarlet fever in Liverpool, Oldham, Huddersfield, Blackburn, and Plymouth; and from "fever" in Preston. The deaths from diphtheria included 44 in London, 7 in Bradford, 5 in Salford, 3 in Plymouth, and 2 in Liverpool. Small-pox caused no death in any of the twenty-eight great towns; and no small-pox patient was under treatment at the end of the week either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and London Fever Hospitals at the end of last week was 660, against numbers increasing in the preceding four weeks from 559 to 623; 108 cases were admitted to these hospitals during the week, against numbers increasing from 33 to 92 in the previous five weeks. The deaths referred to diseases of the respiratory organs in London, which had been 158 and 141 in the preceding two weeks, rose again last week to 160, but were 29 below the corrected average. The causes of 79, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Portsmouth, Brighton, and in three other smaller towns. The largest proportions of uncertified deaths were registered in Liverpool, Salford, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18 6 and 19·6 per 1000 in the preceding two weeks, declined to 17·9 in the week ending July 27th; this rate was 3·1 below the mean rate during the same week in the twenty-eight large English towns. The rates in these Scotch towns ranged last week from 10 8 and 15·0 in Dundee and Edinburgh, to 20 0 in Glasgow and 28·3 in Paisley. The 459 deaths in the eight towns showed a decrease of 41 from the number in the previous week, and included 41 which were referred to diarrhœa, 21 to whooping-cough, 20 to measles, 6 to diphtheria, 4 to "fever" (principally enteric), 3 to scarlet fever, and not one to small-pox; in all, 95 deaths resulted from these principal zymotic diseases, against 81, 91, and 94 in the preceding three weeks. These 95 deaths were equal to an annual rate of 3·7 per 1000, which was 1·8 below the mean rate from the same diseases in the twenty-eight English towns. The deaths attributed to diarrhœa, which had increased in the preceding four weeks from 17 to 38, further rose last week to 41, and exceeded by 20 the number in the corresponding week of last year. The 21 fatal cases of whooping-cough exceeded the number in the previous week by 1, and included 13 in Glasgow, 3 in Paisley, and 2 in Greenock. The deaths from measles, which had been 19 and 18 in the previous two weeks, rose last week to 20, of which 7 occurred in Leith, 6 in Aberdeen, 4 in Glasgow, and 3 in Edinburgh. The 4 deaths from "fever," including

Digitized by Google

3in Glasgow, showed a decline from recent weekly numbers; and of the 6 fatal cases of diphtheria, 4 occurred in Glasgow. The deaths referred to the principal diseases of the respiratory organs, which had been 56 and 69 in the preceding two weeks, declined last week to 55, but exceeded the number in the corresponding week of last year by 6. The causes of 69, or 15 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 16·3 and 22·8 per 1000 in the preceding two weeks, further rose to 24·8 in the week ending July 27th. During the first four weeks of the current quarter the death-rate in the city averaged 21·7, the mean rate during the same period being 18·2 in London and 16·2 in Edinburgh. The 168 deaths in Dublin showed a further increase of 14 upon the numbers in the preceding two weeks; they included 12 which were referred to diarrhœa, 4 to "fever," 4 to measles, 3 to whooping-cough, and not one either to small-pox, scarlet fever, or diphtheria. Thus the deaths from these principal zymotic diseases, which had been 11 and 25 in the previous two weeks, were 23 last week; they were equal to an annual rate of 3·4 per 1000, the rates from the same diseases being 4·4 in London and 2·3 in Edinburgh. The deaths referred to diarrhœa, measles, and whooping-cough were fewer than those returned in the previous week, while those of "fever" showed an increase. The deaths of infants were fewer, and those of elderly persons more numerous, than those in the previous week. Five inquest cases and 1 death from violence were registered; and 54, or nearly a third, of the deaths occurred in public institutions. The causes of 11, or more than 6 per cent., of the deaths in the city were not certified.

"Audi alteram partem."

THE HYDERABAD COMMISSION ON CHLOROFORM.

To the Editors of THE LANCET.

SIRS,—I have referred with interest to the annotations in your issues of Feb. 23rd and March 2nd, and notice with surprise in the report of 128 dogs poisoned with chloroform that, "no matter in what way it was given, in no case did the heart become dangerously affected by chloroform until after the breathing had stopped." The fewer number of experiments performed by myself with the view of finding the best means of procuring resuscitation in cases of chloroform poisoning, and which were published in THE LANCET in 1885, showed conclusively that in some instances the pulse stops before the respiration, but in others the respiration before the pulse. Reference to the detailed reports of my observations[1] also shows that if any impediment to the respiration exists, death results from asphyxia, the respiration ordinarily stopping before the circulation. On the other hand, if all impediment to respiration be removed by drawing forwards both the tongue and epiglottis during the administration of the anæsthetic, when poisoning occurs, it is from cardiac syncope, the circulation stopping before the respiration; although these rules are not invariable. The danger of cardiac syncope may also be reduced by the exhibition of atropine and ammonia prior to the administration of chloroform. In illustration of the fact that respiration sometimes ceases before circulation, and *vice versâ*, allow me to quote the following extracts from some of my experiments already referred to.

Exp. 5.—Weight of dog, 11 lb. At 3.5 P.M. chloroform was freely administered on a towel, with a small supply of air. At 4.1 the respiration ceased entirely. At 4.2 20 sec. the femoral pulses, which Dr. van Duyse and myself had been carefully feeling, ceased.

Exp. 6.—Weight of dog, 16·5 lb. The administration of chloroform was commenced at 6.15 P.M. The pulse became intermittent at about 6.34, and ceased entirely at 6.34 30 sec. The respiration ceased at the same time as the pulse, and could not be restored by artificial respiration, the tongue having been drawn out.

[1] On Transfusion of Blood and Saline Fluid (3rd edition). Baillière, Tindall, and Cox.

Exp. 7.—Weight of dog, 18 lb. Chloroform administered at 11.30 A.M. The pulse became irregular at 11.36, and ceased just before the respiration, at 11.40.

Exp. 8.—Weight of dog, 14·38 lb. Administration of chloroform commenced at 3.34 P.M. Respiration stopped at 3.46. The pulse stopped at 3 51.

Exp. 10.—Weight of dog, 15·2 lb. Chloroform administered at 4.10 P.M. The respiration stopped at 4 24, and the pulse at 4·32.

Exp. 11.—Weight of dog, 11·12 lb. Administration of chloroform at 10.21 A.M. At 10.30 the pulse became intermittent. At 10.34 the pulse stopped entirely, and the respiration directly afterwards.

Exp. 12.—Weight of dog, 7·05 lb. At 11.58 A.M. chloroform was administered. At 12.3 P.M. the pulse became intermittent. At 12.5 the pulse and respiration stopped, but returned after the performance of artificial respiration. Chloroform was exhibited again. At 12.8 P.M. the pulse and respiration ceased, and did not return after the renewal of artificial respiration.

Exp. 13.—Weight of dog, 9·8 lb. At 3.49 P.M. chloroform was administered. The pulse became intermittent at 3.54 P.M.; it stopped completely once or twice, but was restored by artificial respiration. Finally the pulse and respiration ceased at 4.2 P.M.

Exp. 14.—Weight of dog, 16 21 lb. At 10.39 A.M. chloroform was administered. At 10.46 there was irregularity of the pulse, and at 10.47 it stopped. At 10.47 30 sec. the respiration stopped.

Exp. 15.—Weight of dog, 27·09 lb. At 11.49 A.M. chloroform was administered. At 11.53 the pulse became intermittent, and at 11.56 it stopped. At 11.58 the respiration ceased.

Exp. 16.—Weight of dog, 26·32 lb. At 10.40 A.M. chloroform was administered. At 10.50 the pulse became intermittent. The respiration ceased at 10.50 36 sec. The tongue and epiglottis had fallen back, and were both drawn forwards. Artificial respiration was performed till 10.58, the pulse having stopped at 10.55 A.M.

Exp. 17.—Weight of dog, 21·8 lb. At 12.9 chloroform was administered At 12.13 the respiration stopped, and at 12.14 15 sec. the pulse also.

Here are twelve experiments in which the relationship of the cessation of respiration to circulation was noted, and it was found that in four of them (Nos. 7, 11, 14, and 15) the pulse stopped before the respiration; in five of them (Nos. 5, 8, 10, 16, and 17) the respiration stopped before the pulse; and in three (Nos. 6, 12, and 13) the pulse and respiration ceased simultaneously. Of the twelve dogs employed in these experiments, five of them (Nos. 5, 11, 12, 14, and 15) were successfully resuscitated after apparent death by infusing saline fluid into the external jugular vein, with simultaneous depletion and artificial respiration, thus removing a portion of the poisoned blood and stimulating the respiration and circulation. In Experiment 15 six minims of liquor ammoniæ in water were injected hypodermically into the dog twelve minutes before the administration of chloroform, in order to retard coagulation of the blood after cessation of the circulation. Infusion of saline fluid was not commenced till eight minutes after the cessation of the pulse and six minutes after the cessation of respiration, and yet the animal recovered.

I am, Sirs, yours faithfully,

CHARLES E. JENNINGS, F.R.C.S., M.S.

Upper Brook-street, W., July 13th, 1889.

DEPRESSED NIPPLES.

To the Editors of THE LANCET.

SIRS,—I note on page 12 of your issue of July 6th a paper by Dr. Herman on "Professor Kehrer's Operation for a Depressed Nipple." Prevention is better than cure. In my hospital practice, both in and out, my attention has long been given to the great negligence shown by young women and their mothers (who ought to know better) to this small but important organ, and I lose no opportunity, when examining a young female patient, of ascertaining that the nipples are properly developed, and, if not, of pointing out the probable consequences of neglect, with advice as to the future.

When we consider what a pleasure it is to a woman to nurse her baby, we must regard a woman with an undeveloped nipple as an incomplete human being deprived of much lawful enjoyment, to say nothing of the probability

Digitized by Google

of future milk abscess and the possible death of her baby. I have noticed three classes of nipples other than the healthy raspberry-shaped normal form.

1. On a fairly well-developed breast a pimple about an eighth of an inch in diameter and the same in elevation represents the nipple; this will, I believe, in the pregnant and parturient female, enlarge sufficiently for nursing to be effected. I therefore content myself in these cases with directing the patient's attention to her nipples as small and undeveloped, and pointing out their future use, advise her to be careful that they do not become flattened under pressure, or undergo further atrophy. Gentle manual friction by the patient herself night and morning is advisable.

2. In this class we find a fairly well developed mamma and nipple, the former generally flabby, often large. Here from pressure by stays the nipple is flattened and depressed, so as no longer to stand out erect like a raspberry. By drawing attention to the nipple and pointing out the danger of further pressure, by slight friction, and drawing the skin back around the organ, the nipple generally springs out into a correct form; the patient is then told to use the means night and morning herself, and in many cases this slight manipulation effects a cure. In some cases of in-patients I have found it necessary to use the breast-pump.

3. Extreme cases of depressed or inverted nipples, as shown in Fig. 1, page 12, or even more inverted than in that figure. In these cases the breasts are usually small and firm. Here I have often coaxed the right nipple, which seems easier to manage than the left, by the manipulation practised in Class 2, into a normal or semi-normal shape; but the left generally requires something more. Pressing with the left finger and thumb on each side of the nipple I evert it as much as possible; with the other finger and thumb I then seize the nipple as low down as possible and forcibly pull it forwards, stretching its connexions and ducts. When this is repeated regularly, which the patient or her mother can do for her, the nipple by degrees assumes a more normal form. This must be continued to avoid the tendency to revert to the original defect.

I have now under my care a woman who owing to her retracted nipples lost her first baby. While under my notice the nipples were everted by the manipulation described. I have requested her when next pregnant to come to me, and I feel confident that on the next occasion nursing will be properly performed.

I think the duty of advising young girls as to the uses of their nipples and the importance of these organs to them in married life is one generally lost sight of by mothers and medical men. But when I note that surgical operations are performed for depressed nipples, and remember the mothers I have seen deprived of their natural enjoyment of nursing their children, together with histories of severe mammary abscess and babies at death's door from imperfect nipples, I feel that much might be done by early attention to these little but important organs to obviate such calamities.

I am, Sirs, yours faithfully,

ALEXANDER WALLACE, M.D., M.R.C.P.L.,
Physician to the Essex and Colchester Hospital.

July 9th, 1889.

THE CASE OF REGINA *v.* KERR.

To the Editors of THE LANCET.

SIRS,—In your excellent summary of the above trial there are some inaccuracies which it may be as well to correct. The bruise on the head was above the right ear, and not the left, as stated. The cause of death was suffocation due to the presence of food in the windpipe, and not congestion of lungs. There is an important omission with regard to the condition of the heart. Its structure was healthy, but there were disease of the valves (incompetence of aortic and contraction of mitral valves) and remains of a "former attack of pericarditis." I am, Sirs, yours truly,

Carlisle, July 26th, 1889. HENRY BARNES, M.D.

VOTING PAPERS AT THE COLLEGE ELECTION.

To the Editors of THE LANCET.

SIRS,—Mr. Lawson Tait's suggestion seems to me to be an excellent one. The only requisite stipulation which is necessary being that every Fellow who votes in person shall bring his proxy paper with him.

I am, Sirs, yours truly,

Clifton, July 30th, 1889 CHARLES STEELE.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Cumberland and Westmoreland Lunatic Asylum.

THE Cumberland and Westmoreland Asylum at Garlands, near Carlisle, appears to stand high in the estimation of the Lunacy Commissioners. It is declared by them "to maintain its reputation for careful management"; "the absence of serious casualties is creditable"; "it is noteworthy that in this asylum every death has, with one exception, during twenty years been followed by an autopsy; and yet, on the 31st of December last year, there were fifty-nine Irish patients here, and it is often alleged elsewhere that the relatives of such patients have an insuperable objection to the post-mortem examination of their next of kin." The Commissioners further say: "We are glad to learn that it is the practice here, and has long been so, for a medical man to examine the workmen ere they commence their daily work on the land or in the shops."

Hexham.

A short time ago the Hexham rural sanitary authority proposed to reduce the salary of their medical officer from £300 per annum without private practice, to £108 with private practice. This their present medical officer declined to accept, and the Local Government Board has written to the authority stating that they could not, under the circumstances, approve of the reduction, and if the sanitary authority desired to receive repayment from the county fund they must reconsider the matter.—Dr. Maclagan, whose serious accident I noted in a previous letter, is, I am happy to say, doing well

Sunderland.

It is reported that there are at present four cases of small-pox under treatment at the Infectious Diseases Hospital, Sunderland. A sailor who came to the town from Middlesbrough, having previously come from Bilbao, developed the disease. The woman and her two daughters at the house where he stayed have since had the disease, and are under treatment.—The Hartley wing of the Sunderland Infirmary is now finished, but nearly £2000 are required to furnish and free it from debt. With praiseworthy determination the gentlemen who signed the contract refused to allow the wall that temporarily separates the wing from the other portion of the building to be removed until the wing is out of debt. The most urgent representations as to the immediate want of more beds are altogether unheeded, and the blockaded doorway must remain as it is until the money still lacking is raised; but it will be a surprise if the blockade is not raised before the year is out.

Carriage Vibration.

Messrs. Atkinson and Philipson of this city have introduced an improvement in carriage-springs which gives great relief from vibration. This arrangement, which has been fully tested, will prove a boon to medical men and their patients. The whole of the carriage is borne on indiarubber, and the relief to the passenger is surprising, as paved crossings or tram lines are imperceptible as they are passed over, there being an entire absence of the jarring sensation which is so objectionable. The patent, I understand, is about nine months old, and has been used successfully by a local gentleman ever since.

Ingham Infirmary, South Shields.

The annual report of the Ingham Infirmary, South Shields, has been issued, and the record of the year is very satisfactory. There has been an important increase in the workmen's subscriptions, and also in the church collections. The number treated at the dispensary had been 7209; the number of deaths 64. Total number of in-patients 205; number of deaths 15. Dr. Berwick, who had served as junior house surgeon, was appointed by the committee to the post of senior house surgeon, vacated last February by Dr. Fletcher, and the committee trust this appointment may be confirmed by the governors.

Newcastle-on-Tyne, July 31st.

THE EMPRESS OF JAPAN AND HOSPITAL WORK.—The Empress of Japan, wishing to assist the Tokio Female Hospital, has, it is said, been diligently saving out of her "pin-money." In a year this has amounted to about £1500, which has all gone to assist her suffering subjects.

EDINBURGH.

(FROM OUR OWN CORRESPONDENT.)

Action by Lady Medical Students.

THIS case has again been brought into court before Lord Kyllachy, the two lady medical students craving an order to readmit them to the Edinburgh school or for £500 as damages. From the evidence brought forward on both sides, the whole case appears to have arisen out of a quarrel about the obeying of a bye-law; but disagreement upon disagreement, none of them about very important or even edifying matters, followed so closely upon one another that eventually relations became very strained between the students and the principal, and it became absolutely necessary that stringent measures should be taken if the dignity of those in authority was to be properly maintained. Pursuers say they were induced to enter upon the course of study upon the faith that defenders would provide them with the whole course necessary to qualify them for practice. The defenders, on the other hand, claim the right to alter or discontinue the whole or any of the courses of lectures. They say also that a new prospectus had been issued before the action was raised, in which was a clause reserving the right to the committee to judge of the progress and general conduct of any student, and declining to readmit a student if they thought it expedient. As to the quarrel, it appears that there was a regulation that students were all to leave the hospital by 5 o'clock in the afternoon. In June last an accident case was admitted to the wards at 5 o'clock, and the students went round to see it. The house-surgeon began to explain the case, and whilst this was being done the lady superintendent appeared and asked, "What is the meaning of you students being here after 5 o'clock?" The students left the hospital about 5.15 P.M. For this they were suspended for a week. Then came a quarrel about some certificate in regard to which the students were asked to express an opinion, and then those who held certain views were evidently stamped as black sheep. The lady superintendent at Leith Hospital, giving evidence, said that the 5 o'clock rule was not a popular one with the students, as they did not care to be hurried away if there was anything interesting going on in the wards at the time. Apart from that incident she never had occasion to find fault; the pursuers were kind to the patients, attentive to their work in the hospital, and they were liked by the other girls and nurses. Evidence was also given to the effect that the pursuers had not caused disorder in the school, and that one of them especially had an influence for good among some of the students. It came out, further, that the school was falling off in popularity with some of the students, and that there was a good deal of discontent as to the manner in which they were treated, it being thought that they were dealt with too much as if they were children. This appears to be the case, as one of the regulations appears to be that the students shall not stop to converse with, or ask questions from, their lecturers at the end of the lecture hours. The Principal of the school said that she considered it insubordination if a friend of a student accused of dishonourable conduct took the student's part. She further stated that she did not think it was a serious thing for ladies to be refused readmission if they could go to London or Dublin. The whole affair really appears to border on the ridiculous. The relations between students and teachers appear to have been most cordial, except on certain points which might have been better discussed *in camerâ*. A too slavish adherence to petty, and, from what one knows of the working of teaching hospitals, almost "impossible" rules and regulations, has led to the present state of matters. Such is evidently Lord Kyllachy's opinion, for, after hearing the evidence on both sides, he expressed the hope that before the case came up next session the parties would try to bring the matter to an end.

Imbeciles in Private Lodgings.

Kennoway, in Fife, is perhaps one of the most depressing spots of earth on which a visitor could alight. It appears to be populated principally by imbeciles. Commenting on a case of indecent assault on an imbecile woman, in Kennoway, the Sheriff in the Dundee Sheriff's Court said that the offence was a most disgusting one and an outrage upon human nature. The woman who had been assaulted was boarded out by the Edinburgh authorities, and he expressed the opinion that the boarding out of large numbers of insane women was subversive, to a great extent, of the morality of the district. Anyone who knows the district referred to will fully corroborate the above opinion, and it is to be hoped that the question thus raised may have the earnest attention of those responsible for the welfare of these poor imbeciles. A little extra expense might have to be incurred by placing them in regular and well-appointed institutions for the insane, but the results would be well worth the extra expenditure.

The Triple Qualification.

The following are the results of the quarterly examinations held in Edinburgh during the month. At the first examination, of 65 candidates 45 passed; at the second, only 19 out of 44 candidates were successful; and at the final, 40 out of 79 were successful. During the half-year ending June 30th, 11 candidates were, after examination, elected as Fellows of the College of Surgeons, and 2 were elected without examination; 7, having passed the required examination, were admitted as Licentiates of the College.

Edinburgh, July 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

DUBLIN.

Annual Report of the Local Government Board for Ireland.

FROM the seventeenth annual report which has been lately issued it appears that there has been a further decline in the average daily number of persons relieved in the workhouses, while there has also been a considerable decrease in the average daily number of persons who received out-door relief. The average daily number in the workhouses was 44,729, and on out-door relief 63,680, or a total of 108,409, which was less than the average daily number relieved in and out of the workhouses in the previous year by 2655. During the year ended January 14th last, the total number of deaths in the various workhouses was 9892, showing a decrease of 295 deaths as compared with the number for the previous year. Of these, fever caused 356, against 383; lung disease 1717, against 1754; and small-pox 1, against 3 in the year preceding. There were for the twelve months ending September 29th, 53,074 admitted into workhouses for sickness, being an increase of 1830 as compared with the previous year; an increase of 6965 in the number admitted who were not sick, and of 415 in the number suffering from fever or other contagious disease. In the various dispensary districts, the medical officers during the year attended 408,554 new cases at the dispensaries, and 186,106 patients at their own homes, or a total of 594,660; and vaccinated 92,498 persons. The vaccination returns show a decrease of 3991 as compared with the year preceding; of the 92,498 persons vaccinated, 76,910 were under one year old when vaccinated, 12,717 above one year, and 2871 were revaccinations. Small-pox during the year caused one death in workhouses, the same as the year previous; and the number of cases of this disease treated in dispensary districts under the Medical Charities Act was 30, or an increase of 12 as compared with the previous return. As regards fever, there were 4357 cases attended by dispensary medical officers, being a decrease of 735; also a decrease of 19 in the number of cases of scarlatina, the numbers being 4357 and 5092 respectively. The medical charities expenditure amounted to £158,996 7*s.* 10*d.*, under which heading is included the cost of medicines and medical appliances, salaries of medical officers and apothecaries, vaccination fees, and other expenses, showing an increase of £620 over that of the previous year. The Commissioners sanctioned loans amounting to £182,182 5*s.* 1*d.* to various towns in Ireland, principally for sewerage and water-supply, which, added to previous sums allocated, constitute a total of £1,896,479 11*s.* 3*d.* for the past fourteen years.

King's Professor of Midwifery, Trinity College, Dublin.

On Friday last the Fellows of the College of Physicians, in whose hands the appointment lay, elected Dr. A. V. Macan King's Professor of Midwifery, in the vacancy created by the death of Dr. Kirkpatrick, a result which was generally expected. Dr. Macan is Master of the Rotunda Lying-in Hospital, and was elected, I understand, by a large majority of votes. The emoluments of the post consist of

Digitized by Google

£100 per annum, the fees for clinical lectures in Sir Patrick Dun's Hospital, and such proportion of the class fees as may be arranged by the President and Fellows.

Payment of Medical Officers' Substitutes.

The guardians of the North Dublin Union last week adopted a resolution to the effect that the locum tenens of each of their medical officers be paid by the board for attendance during the month's leave of absence. It was carried by 17 to 15, but one of the guardians has given notice that he will move to have the resolution rescinded.

British Dental Association.

The sixth annual meeting of the Irish branch of this Association was held at the Royal College of Surgeons on Saturday, and was presided over by Mr. Robert H. Moore. Some interesting inventions and new dental instruments were exhibited at the meeting.

Dublin, July 30th.

BELFAST.

The Ulster Medical Society.

The annual meeting of the Ulster Medical Society was held in the Museum, Belfast, on July 24th, when the report of the Council, giving an account of the work done in the past year, and the treasurer's statement were submitted. There is a balance in favour of the Society of £112 5*s.* 1*d.* Mr. McConnell was elected president for the coming year, Dr. McCaw secretary, and Dr. O'Neill treasurer. At the meeting a discussion took place as to the desirability of forming a medical club in Belfast, where the various societies could hold their meetings. It was thought the time had come when such an undertaking might prove successful, and a committee was formed to consider the matter and to draw up a report. It was also the feeling of those present that a good medical library could be incorporated with the club.

North of Ireland Branch of the British Medical Association.

The eleventh annual meeting of the North of Ireland Branch of the British Medical Association was held in the Royal Hospital, Belfast, on July 18th. Dr. Gray, J.P., Castlewellan, was elected president for the ensuing twelve months, and Dr. Byers secretary. Dr. Dill delivered the presidential address on "Forensic Medicine and Medical Evidence." Dr. Thompson (Omagh), Dr. Dempsey, Professor Sinclair, and Dr. O'Neill brought forward communications. In the evening the annual dinner was held, when Dr. Dill presided, thirty-three members being present.

The Royal Hospital.

About two weeks ago arrangements had been made to give the public of Belfast and the north of Ireland an opportunity of visiting the new steamer *Teutonic*, the largest vessel afloat. The various steamboat companies had promised to take passengers free down the Belfast Lough to the vessel, and each visitor was to pay a charge of two shillings on boarding the steamer, all the proceeds to be handed over to the hospital. Unfortunately, it was found impossible to have the vessel ready in time owing to the July holidays, and on Saturday last a communication was read at a meeting of the Board of Management of the hospital regretting this, and enclosing a cheque for £200 from Messrs. Harland and Wolff, the builders of the *Teutonic*.

Election of Coroner in Mid-Antrim.

A very active canvass is being carried on by the two gentlemen who are in the field for this office. One of the candidates is a lawyer; the other a medical man, Mr. J. Dysart McCaw of Portglenone. From what I hear, it is probable that the latter will be appointed. He is well known and popular in the district, and a very strong committee is energetically working for him.

Belfast, July 30th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Inheritance of Syphilis.

IN a recent communication on this subject I gave a *résumé* of one part of the important contribution to the study of heredity in syphilis given by that distinguished syphilographer, Professor Fournier, in the form of the remarkable lecture at the delivery of which, on a recent occasion at St. Louis, it was my privilege to be present. In the concluding portion of this eloquent address he discussed the question, Whence comes the hereditary poison of syphilis? Does it descend through the father or mother, or both? On this point, he said, the most opposite opinions were held; indeed, hereditary syphilis was a veritable apple of discord cast into the camp of observers. He did not pretend to reconcile these various views; he would rather endeavour to place before his hearers first the points generally admitted, and then those surrounded by certain obscurities which time alone would clear up. And to begin with, it might be asked whether true hereditary syphilis followed when both parents were in a state of syphilisation. Now this, by way of exception, was a point not disputed. All were agreed that it could and did follow; indeed, examples illustrating this were to be found in the wards at present. Moreover, the influence of the poison did not cease with one pregnancy only, but might be manifest in several subsequent pregnancies, numerous instances of which the speaker cited, and which were sufficiently conclusive. He next took the case of each of the parents separately affected, commencing with maternal heredity. On this score he remarked that affirmative accord was pretty unanimous, although he insisted at considerable length that the demonstration was by no means so simple a matter as it might appear at first sight. He pointed out the many pitfalls to be avoided in tracing out logically the infection from the maternal side alone, and showed that false deduction was as easy as it was common. Indeed, he added, after twenty-eight years of study and practice, he knew of thirteen examples only amongst women whose cases fulfilled all the conditions necessary for a perfect demonstration. In the result, however, he made it clear that maternal syphilitic heredity certainly existed, as *a priori* one might suppose. Moreover, there was, added to other proofs, an anatomical demonstration of this transmissibility which the recent researches of MM. Mathias Duval and Van Beneden on the anatomy of blood-circulation in the placenta had established. These gentlemen showed that the circulation in this organ was not, as was formerly believed, a mere bringing into close juxtaposition of the maternal and fœtal blood only while each was independent of the other, but that the placenta was rather a sort of maternal hæmorrhage encysted by fœtal structures, in which the fœtal elements were bathed in the blood of the mother. Was it possible, then, that under such conditions the transmission of the malady should not take place? And, further, it was easy to cite certain morbid analogies in favour of this thesis; for the placenta, which had hitherto been looked upon as an impassable barrier, was in reality now known to be permeable, not only to liquids, but to microbes, bacilli, &c., as was proved by the experiments of MM. Straus and Chamberland, which showed that the bacteria in charbon filtered through the placenta, and were consequently transmitted from mother to fœtus. Again, the same thing had been proved as regarded the bacillus of enteric fever, which had been found in the blood of a fœtus, the mother being dead of typhoid. Why, then, should not a like transmission take place in syphilis, the microbe of which was so attenuated that hitherto it had escaped detection? Theoretically and clinically, therefore, maternal hereditary syphilis was demonstrable. Taking up, next, the question of the inheritance of syphilis through the father, Professor Fournier remarked that this was the most debated point in the problem, and one of the most important, especially as to the fitness or not of a man for marriage. In former times paternal hereditary syphilis was allowed to be almost a thing without question. Cazenove held the opinion that syphilis was more often transmitted through the father than the mother. Since 1851, however, views directly opposite had been largely advanced, representing paternal heredity as a fact more or less rare and exceptional; it had even been held that the paternal influence was *nil* in that which concerned the transmission of syphilis to the fœtus. This doctrine, M. Fournier emphatically maintained, was false. It was furthermore dangerous, for it exonerated syphilis from a great number of the hereditary perils which were inherent in it, and opened imprudently the gates of marriage to individuals whom a legitimate apprehension for their possible offspring now deterred. The advocates of this view pinned their faith mainly on the manifest disproportion between the number of syphilitic fathers and that of the syphilitic children born to them, and on the undoubted fact that not infrequently one saw

Digitized by Google

examples of perfectly healthy infants the issue of obviously syphilitic fathers. But these were negative facts, and proved at the most that the disease did not invariably exercise its hereditary influence. They were, in brief, the exceptions which support rather than gainsay the statement that inheritance was the rule. Another interesting point which the upholders of this theory make turned upon the well-grounded assertion that syphilis could not be conveyed by inoculation with the semen of a syphilitic person, and they argued from this that the spermatozoa of such a person could not contaminate the ovule, and that, therefore, paternal heredity did not exist. But there was surely no parallel to be established between the negative results of inoculation by seminal fluid, and the effects of this fluid on the ovule. To the ovule, by phenomena at once special and mysterious it gave life, and transmitted at the same time the physiological and pathological peculiarities, the characteristics of race and individual, which became manifest later on in the physical, moral, and morbid resemblances between father and child. It was consequently not astonishing that the semen should be able to transmit syphilis, as it did any other morbid trait, while at the same time it failed to communicate it by ordinary inoculation. But, over and above all this, the clinical evidence in favour of paternal heredity placed its existence beyond cavil. In the first place, one had time out of number seen infants the issue of a syphilitic father and of a mother healthy at least in appearance to be the subjects of undoubted hereditary symptoms. To this fact witness was borne by such eminent observers as Ricord, Trousseau, Hardy, Hutchinson, and others. Again, the predisposition to abort in the mother, brought about by the syphilitic state in the father, was another powerful argument in support of the paternal influence. Of 103 pregnancies in perfectly healthy women allied to syphilitic husbands, forty-one, or 30 per cent., were known to the learned Professor to have terminated in abortion or premature labour. These statistics were culled by him, not from amongst poor and uncertain hospital patients, but from his better class of private patients, women who were young and healthy, living under the most favourable social, and surrounded by the best hygienic, conditions. Then as a corollary there was the further evidence to be derived from the effects of treatment on the tainted parent, who before being treated had begotten nothing but abortions, so to speak, ended, after being subjected to a beneficial regime, by becoming the father of healthy offspring. Finally, the hereditary paternal influence was illustrated by what he termed the conceptional syphilis of the mother. By this he meant those cases of previously healthy women pregnant by a syphilitic father, who developed syphilis in the course of their pregnancy without the male parent betraying the least lesion capable of communicating contagion directly. It was clear that the infection here, which had quite a distinct clinical sequence, could not be attributed directly to the father, but, on the contrary, to the fœtus, which in its turn had only the father to look to for its morbid inheritance. From all this testimony, added M. Fournier, there could be no doubt that the existence of hereditary syphilis traceable exclusively to paternal sources was a clinical truth. He concluded by enunciating the causes which had led to misconception and doubt on this point. These arose largely from the fact that in a considerable number of instances the taint was not passed down. Numerous examples were at hand of syphilitic fathers begetting perfectly healthy children. And, also, they had their origin in another indisputable fact which was less recognised and remembered—viz., that hereditary syphilis manifested itself much less frequently by the birth of children who lived to develop the various sequelæ of their inheritance as commonly understood, than by other phenomena ending in their destruction. In other terms, paternal syphilis killed the infant more often than it limited itself to transmitting syphilis. Amongst this class of manifestations must be placed abortions, premature labours, death of infants from "consumption" without cause, convulsions, hydrocephalus, &c. In the 103 pregnancies which he before referred to, 17 resulted in the birth of children with early and 2 with late development of hereditary symptoms; whereas 41 were abortions and 43 were the cases of early death of the infant, so that the transmission of the hereditary taint occurred in 18 per cent., and the causation of the death of the offspring in 81 per cent. He concluded his address, which was listened to attentively by a large audience, by saying he would deal with the more practical phases of the subject in his next lecture.

M. Chevreul's Library.

The heirs of the late M. Chevreul have presented to the Museum of Natural History his library, amounting to 10,000 volumes, as well as several manuscripts on chemistry, alchemy, &c. A pupil of M. Chevreul is engaged in preparing, for communication to the Academy of Sciences, a chart of colours derived from coal-tar, which are now so much employed in commerce according to the remarkable theory of the illustrious chemist.

A Bonus on Fecundity.

With the view of encouraging the multiplication of the French nation, the Chamber of Deputies have adopted a proposition made by Dr. Javal to the effect that fathers or mothers of seven children should be exempt from personal or house taxes.

Hydrophobia and the Pasteur Method.

The *Petit Moniteur* of July 18th reports that about fifty days ago a lad of thirteen named Louis Trottet, living with his parents in the Rue Duméril, was severely bitten on the leg by a rabid dog. The wound was cauterised almost immediately after the accident, and the patient was taken to the Pasteur Institute, where he was submitted to the usual treatment. On the 15th, the patient having till then felt quite well, was suddenly seized with symptoms of hydrophobia. The doctor who saw the patient in the first instance was again called in, and he sent the patient to the Pitié Hospital, where he died in a few hours. This report is confirmed by the *Semaine Médicale* of July 24th.

M. Joffrin.

M. Joffrin, Vice-President of the Municipal Council of Paris, who was operated on some two or three years ago for an epithelial cancer of the lip, has had a return of the malady, and has entered the Hôpital Bichât for treatment. The surgeons are doubtful whether another operation can be usefully performed.

Paris, July 30th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The New Professor of Botany in Berlin.

PROFESSOR ENGLER of Breslau has, after many difficulties, been appointed to the chair of Botany in Berlin University, which has been vacant since Eichler's death three years ago. Adolf Engler laid the foundation of his fame as a botanist by his minute study of a single species of plants, the stone-breaks, the final results of which he published in 1872. From this special study he passed to one of more general interest, and published in 1879–82 his "Versuch einer Entwickelungs-geschichte der Pflanzenwelt" (Attempt at a History of the Development of the Vegetable World), taking up the subject where Darwin dropped it. The book excited unusual attention among botanists. Of Engler's other writings, two deserve special mention—viz, his contributions to the Flora Brasiliensis (a great work begun by Martins, carried on by Eichler, and now by Urban), and his notes on the Flora of the Baltic, written for the Scientific Commission for the Investigation of the German Seas. As a university teacher Engler has taught in Munich, Kiel, and Breslau. At Munich he was also keeper of the Botanical Garden. He was called to Kiel in 1878 and to Breslau in 1884. His predecessors in the Berlin chair since the founding of the University in the beginning of this century were Wildenow, Link, Braun, and Eichler.

The History of Medicine.

Dr. von Gossler, Prussian Minister of Religion, Education, and Medicine, desires to revive the study of the History of Medicine in the Prussian Universities. Of all the German and Austrian universities only Berlin and Vienna have chairs of Medical History; there used to be one in Breslau, but it has remained vacant since the death of its last occupant, Heinrich Haeser. In several other universities medical professors are entrusted with the teaching of this subject along with their special ones, but they seldom do so. A noteworthy proposal, with a view to the reanimation of this branch of study, was made by Dr. Max

Digitized by Google

Salomon in 1871, and publicly repeated by him three years ago. It is that one of the librarianships in each university be given to a man versed in the history of medicine, and that he be at the same time appointed professor of that subject. This arrangement, he thinks, would not only fill the above indicated gap in the medical curriculum, but also secure greater attention to the wants of medical men in the libraries, the want of which is severely felt. At present, for instance, there is not a single medical man in the service of the Royal Library in Berlin. Dr. von Gossler is well aware of Dr. Salomon's idea, and it is not unlikely that he will realise it.

Professor Virchow as Anthropologist.

In the forenoon of the 23rd inst. the natives of Central Africa of the Djanghani tribe, at present on show in the Charlottenburg Flora, were carefully measured by Professor Virchow, in the presence of his assistant, Dr. Hansemann, and several members of the Anthropological Society. Professor Virchow was surprised by the deep blackness of the skin, relieved in only two of the negroes by a faint red on the cheek bones. In the giant Abdallah not even this trace of redness is visible, and his skin is the blackest that has ever been seen here. The ears, hands, and feet of these negroes are surprisingly small, whereas their arms are remarkably long. Their foreheads are tattooed ringwise, with singularly shaped cuttings in the skin. Professor Virchow spent six hours in measuring them, &c., and, when he left them to lecture in the Pathological Institute, the measurements were continued by Dr. Hansemann. With the help of an interpreter, whom Professor Virchow had taken with him, the native names of the Africans were ascertained. The giant's name is Kueck, that of his partner in the fighting scenes Schur, that of the musician Hadyak, and that of the woman Adjull. Their Mohammedan names were given them in Egypt. Professor Virchow took several photographs of them with his own hands. They repeatedly gave comical expression to their surprise at the many manipulations to which they were subjected, the purpose of which was unintelligible to them.

The Emperor Frederick Fund for Convalescents.

More than a year ago a benevolent person, who wishes to be anonymous, entrusted the sum of 40,000 marks to the head of one of the great Berlin hospitals, with the request that the interest should be spent for the benefit of poor convalescents. In April, 1888, the Emperor Frederick gave permission that the fund should bear the name "The Emperor Frederick Fund for Convalescents," and expressed his deep sympathy with the purpose of the founder. The statutes, however, have not yet been sanctioned by the authorities, and so the purpose of the founder has not yet been realised in full measure.

An Anthropological Congress.

A congress of Austrian and German anthropologists will meet in Vienna from the 5th till the 10th of August, with Professor Virchow as president. After the Congress the members will make a three days' excursion together to Buda-Pesth.

Dr. Rudolf Schelske.

Twenty-five years ago last Monday the oculist, Dr. Rudolf Schelske, established himself as a private lecturer in the University of Berlin. Like Professors Schweigger and Hirschberg, his fellow-teachers of ophthalmology here, he was an assistant and fellow-labourer of Albrecht von Graefe. The most important of his contributions to the literature of his department are his investigations of the membrana limitans of the human retina, of the perception of colour, of red-blindness, and of the curvature of the cornea. His largest work is his "Manual of Ophthalmology," in which he adheres to Graefe's classification and faithfully reproduces his views.

Medical Publications.

The following are amongst the more recent publications:—"The Tending of the Sick," by Army Surgeon Dr. Riebel, is intended for the use of the school for sick attendants in the Charité in Berlin. It is very intelligibly written. "Massage and Cognate Methods," by Dr. Preller. "The Application and Effect of Electricity in Medicine," by Dr. Wichmann. "Diet and Guide for Heart Patients," by Dr. A. Lange. "Hints for Sufferers from Diabetes," by Baron von Lühdorf. "The Normal Child," by Frau Anna Woas, which aims at teaching mothers how to bring children up healthy, good, and comely. "The High Importance of the Milk Teeth for the Development of the Permanent Teeth" (a word of warning to parents and teachers), by Constantine von Koziczkowski, dentist. "Croup and Diphtheria," by Dr. Leonhardi. "The Hot-Air Treatment of Tuberculosis of the Lungs," by Dr. Louis Weigert. "Modern Cremation," by Sir H. Thompson, translated by Dr. Paul Cohn.

The Central Help Fund for German Physicians.

The members of the Central Help Fund for the Physicians of Germany have chosen Professor Leyden as their president, in place of the late Geheimerath Abarbanell. The sum bequeathed to the fund by Dr. Emil Müller amounts, as far as is yet ascertained, to about 750,000 marks (£37,500). A widows' and orphans' fund is to be established next year.

A recent number of the *Vossische Zeitung* contained a minute description by a New York correspondent of the newest American method of preserving corpses by desiccation in enormous mausoleums built of concrete.

Dr. Stahl, Professor of Botany at Jena, will go to Java next October, and spend some time in botanical researches there.

Berlin, July 28th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

American Surgical Association.

THE annual session of this body has just closed. The number of members is limited to 100; there are now eighty-nine, and fifteen honorary members. The session was occupied with the discussion of the more prominent subjects which now interest surgeons. "Sarcoma of the Tonsil" was the title of a paper by Dr. Cheever. He gave a full description of the case and the methods of excision, with charts as to feeding and closing the larynx. Hernia was considered in detail, both as to its radical cure and when gangrenous. The early diagnosis of Morbid Growths was discussed by a number of members, and this was followed by a paper on the Free Division of the Capsule of the Kidney for the Relief of Nephralgia. A successful case of Digital Dilatation of the Pylorus was reported and discussed. Gunshot wounds of the intestines were considered at length. The Association is in a very satisfactory condition, and annually issues a volume of Transactions of great merit.

American Medical Association

This Association has just held its fortieth annual session at Newport. The attendance was not as large as usual, but the meeting was full of interest to the members present. Upwards of 700 physicians registered; the attendance has numbered 1200 members in other years, when the place of meeting was more central. At the general meetings discourses were delivered on Surgery, Medicine, and State Medicine, but the chief interest centred in the meetings of the sections, where papers on current medical and surgical topics were read and freely discussed.

Dangers from Electric Wires.

The frequent accidents from the breaking of electric wires is exciting much public interest. In several instances horses have been instantly killed by the sudden parting of these wires, the ends of which have fallen upon the animals while passing under. Recently a wire fell, broken, in front of a team. The driver seized the wire to throw it aside, when he was convulsed by the electric current, but could not release his grasp. A gentleman seized him by the arm to pull him away, and was himself instantly prostrated. A second man attempted to push the wire aside with his cane, and was paralysed. A dog approached, and, touching the wire with his nose, instantly fell insensible. At length a workman cut the wire with the stroke of a hatchet or axe, and thus released the first victim, who is slowly recovering. The city authorities will now compel all electric companies to bury their wires in properly enclosed and protected subways.

Monument to Dr. Rush.

The Committee of the American Medical Association engaged in securing the funds for a statue of Dr. Benjamin Rush report that, after five years' labour, they have obtained but $1000 of the $40,000 required. The original basis of subscription was one dollar from each physician,

Digitized by Google

and, as there are 100,000 physicians in the United States, it was believed that the fund would be readily secured, as at least one-half the number would be only too anxious to subscribe. The total failure of this calculation greatly surprised the committee, and embarrasses their future action. The committee will, however, continue their efforts; but the chairman facetiously remarked that the members would long be dead when the desired sum was raised.

Tenement House Mortality.

A recent report by the City Registrar shows that the mortality in the tenement houses, in which half of the population live, is less than that in private residences. This is owing to the constant work of the Board of Health in these dwellings. Ventilation, cleansing, and careful supervision of foods have been the chief factors in these improvements. A summer corps of physicians has been appointed to visit the tenement houses daily, and, besides improving their sanitary conditions, these physicians treat promptly the incipient diarrhœal affections, and thus greatly diminish the summer mortality.

New York, July 15th.

THE SERVICES.

ARMY MEDICAL STAFF.—Surgeon-Major William Venour has been granted retired pay (dated July 14th, 1889); Surgeon Richard Ernest Foot, M.D., resigns his commission (dated July 31st, 1889).

MEDICAL STAFF CORPS. — Colonel William Gordon, Bengal, has been transferred to the Unemployed Supernumerary List (dated July 15th, 1889).

MILITIA (Infantry).—3rd and 4th Battalions, the Manchester Regiment: John Brunt, Esq., late Surgeon Royal Navy, to be Captain (dated July 12th, 1889).

VOLUNTEER CORPS.—*Artillery:* 5th Lancashire: Surgeon R. Clark resigns his commission (dated July 27th, 1889).—9th Lancashire: Surgeon R. Patrick, M.D., to be Surgeon-Major, ranking as Major (dated July 27th, 1889).—1st Inverness-shire: The undermentioned Acting Surgeons to be Surgeons:—O. Grant, M.B. (dated July 27th, 1889); J. M. Chapman, M.B. (dated July 27th, 1889).—*Engineers* (Fortress and Railway Forces): 2nd West Riding of Yorkshire (Leeds): Acting Surgeon F. Robinson, M.B., resigns his appointment (dated July 27th, 1889). — *Rifle:* The Queen's Rifle Volunteer Brigade, the Royal Scots (Lothian Regiment): Surgeon-Major (ranking as Lieutenant-Colonel) A. G. Miller resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Regiment on his retirement (dated July 27th, 1889).—2nd Volunteer Battalion, the Suffolk Regiment: Surgeon J. S. Holden, M.D., to be Surgeon-Major, ranking as Major (dated July 27th, 1889).—5th (Deeside Highland) Volunteer Battalion, the Gordon Highlanders: Acting Surgeon R. Cran, M.B., resigns his appointment (dated July 27th, 1889).

ROYAL COLLEGE OF SURGEONS.

AN ordinary meeting of the Council was held on Aug. 1st.

The minutes of the Quarterly Council having been read and confirmed, the President reported that Mr. Thomas Bryant had been chosen as Bradshawe Lecturer for the present year.

On the report of the President and Vice-Presidents, the Council appointed Sir James Paget (as trustee), Mr. Jonathan Hutchinson (president), and Sir Wm. MacCormac as members of the standing committee of the "Father Damien" Memorial Fund, the nomination of the members of the proposed commission being reserved till the scheme shall have been further developed.

The President stated that, in order to give effect to the new bye-laws relating to the new Dental diploma, it would be necessary to elect, at the quarterly Council, two new members of the Dental Board, one from amongst the members of the Court of Examiners, and the other a registered Dental Licentiate, on a report from the Nomination Committee.

It was resolved that the quarterly Council should be held on the third Thursday in October (Oct. 17th), instead of the second. On a motion by Mr. Durham, it was resolved that a copy of the bye-laws should be given to each candidate before his admission to the membership at such time as may be judged convenient.

Obituary.

COUNT PIETRO LORETA.

AT Bologna on the 23rd ult., this great surgeon and estimable man was borne to the grave amid every demonstration of reverence and sorrow—reverence for the good he had done to the profession and to mankind, sorrow for the tragic fate that had closed a career still bright with promise though already full of achievement. Three days before he died by his own hand, in circumstances peculiarly appalling. In the spring of the present year there was held at Bologna the Medico-Chirurgical Congress, a special feature of which was the progress made in abdominal surgery, chiefly by Prof. Loreta and his pupils. We summarised at the time the interesting monographs and discussions on the two operations which will always be associated with the name of Loreta—"resection of the liver," and "digital divulsion of the pyloric and œsophageal orifices of the stomach." So proud were his students and his Italian brethren of the bold, assured skill and the success with which, for the first time in the annals of surgery, he had performed these operations that they erected in his honour two tablets commemorating the fact—one in the clinical wards of the Bologna Infirmary, another in the anatomical theatre of the University. Distinctions, indeed, of every kind had come to him from European and transatlantic schools, and it was known that other honours awaited him. Beloved by his pupils and colleagues, admired and respected by compatriots and foreigners alike, Loreta seemed to the outside world one of fortune's favourites, when, but a few weeks ago, a shadow overclouded his intellectual and moral powers, deepening apparently from day to day. Previously one of the most vivacious and cheery of men, he gradually betrayed symptoms of melancholia, and incidents like the following aroused the suspicions of his friends. He used to visit the Casa di Salute, directed by Dr. Benedetti, having several patients under treatment there; but one morning he found it shut, with the announcement at the doorway "Furnished apartments to let." On asking Benedetti, with a dejected look, what it all meant, he was told the Sanitary Commission had just ordered the house to be suppressed, whereupon he said, "And this is progress! See how they persecute me! To get rid of this *camorra* it would be well to try the revolver!" Benedetti marvelled at the words, but as Loreta went about his work as usual he did not divulge his fears. On Thursday, the 18th ult., the professor had gone, on consultant business, to the neighbourhood of Rovigo, whence he returned in the early morning of Friday, about 4.30 A.M. He went to bed for a few hours, and rose at 10 A.M., when his servants remarked he looked particularly downcast. Having breakfasted about mid-day, he took a turn in the garden, then retired to his room, giving strict orders not to be disturbed. Telegrams, messages, visits—all the engagements of his extensive practice had to wait for him, till about 3 P.M. he told his servant to take a letter for him to the Advocate Cenni, the answer to which, however, was not to be brought to him till after 4 o'clock. Immediately on perusing it Cenni was filled with the gravest fears, Loreta having intimated that he was weary of life and of the war waged with him by his persecutors, that he meant to destroy himself, and that his will would be found in a certain place. Cenni hastened to the Questura, and, accompanied by the police and civic authorities, drove at once to Loreta's house. At the professor's door no answer was given to repeated summonses; an entrance was forced, and then the worst suspicions were more than realised. The unhappy man was found lying on a double bed, quite dead from deep wounds inflicted by a razor in the inguinal region. The jet of blood from the severed arteries had stained a Crucifixion of Guido Reni's above the bed, which was itself saturated, while within reach of his hand lay a six-chambered revolver still undischarged. The face wore a

Digitized by Google

tranquil, even smiling expression, as if of relief from a burden too grievous to be borne.

The consternation that overspread Bologna when the tragedy became known was indescribable. Count Loreta, a man of birth and fortune, a representative of the first division of the city in the Parliament of Italy, the working patron of many charities public and professional, the glory of the medical school, the ornament and support of the University, seemed the last among her citizens whom such a miserable end could have overtaken. From Bologna the sad impression speedily diffused itself over Italy and wherever the name of the most distinguished of Italian surgeons has penetrated. There were, indeed, few professional societies on the Continent of which Pietro Loreta was not a corresponding member, while his numerous papers and monographs, including the two already referred to, had made him known to the chief medical schools of both hemispheres.

His funeral was one of the most imposing ever witnessed in Bologna. Every shop was closed and every house was draped in mourning, as the long procession, in which all the professional and academic life of Italy was represented, wound slowly through the crowded, silent streets to the Porta Sant' Isaia, where the customary *oraisons funèbres* were pronounced over the bier.

Count Pietro Loreta was but fifty-eight years of age, a native of Ravenna, but a Bolognese since 1865, when, after having graduated at the University with distinction, he became professor of surgery, theoretical and clinical, and entered on the brilliant career which has been so tragically cut short.

Medical News.

VICTORIA UNIVERSITY: FACULTY OF MEDICINE.—The following gentlemen have passed the respective Examinations mentioned:—

Preliminary Examination in Science.—First Division: H. Ainsworth, Owens College; W. M. Brown, University College; E. Harrison, A. W. Lilley, and A. MacDougall, Owens College; E. E. D. Minshall and H. T. Nixon, University College; D. Seaton, Yorkshire College; and P. Thompson, Owens College.—Second Division: R. E. Bickerton, University College; J. C. Buckley, W. J. S. Bythell, D. H. Cheetham, E. L. Compston, and E. A. Goulden, Owens College; W. D. Hayward, University College; H. C. Heathcote, Owens College; S. H. House, University College; J. Howe, M. B. James, and A. Leigh, Owens College; E. H. L. Lindon, University College; F. S. Mathwin, Owens College; T. U. Mercer and A. H. Quinby, University College; M. R. Rhodes, Owens College; H. A. Robinson, University College; L. E. Scanlon, Owens College; B. Stahlknecht, University College; F. A. Storr and C. F. Thompson, Yorkshire College; and J. D. Whitaker, Owens College.

Intermediate M.B. and Ch.B. Examination.—First Division: *J. W. Crawshaw and J. H. Taylor, Owens College.—Second Division: W. E. Barker, Owens College; J. C. Bawden, A. Bicknell, and S. R. Knight, University College; C. H. G. Ramsbottom, H. K. Ramsden, W. C. Rigby, G. Stowell, and W. H. Waddington, Owens College.

Final M.B. and Ch.B. Examination (Part I.)—A. E. Brindley and T. F. Daniels, Owens College; J. Gould, University College; W. Griffith, Owens College; J. M. H. Martin, University College; A. H. Poole and F. Robinson, Owens College; J. Teare, University College; and L. Youatt, Owens College.

Final M.B. and Ch.B. Examination (Part II.)—First Division: †A. E. Brindley, ‡T. N. Kelynack, R. E. Lord, and J. S. McGowan, Owens College.—Second Division: R. Alcock, A. Ashton, J. Dunlop, and C. F. Marshall, Owens College; E. Molyneux, University College; T. Porter, J. Simcock, F. W. Stansfield, J. N. Unsworth, and A. B. Watson, Owens College.

The following gentlemen have satisfied the Examiners in the examination for diplomas in Sanitary Science:—

W. B. Barclay, J. Brown, A. Chadwick, W. Dearden, W. Dick, F. W. Jordan, and W. Sellars, Jun.

* Distinguished in Anatomy.
† Distinguished in Obstetrics.
‡ Distinguished in Medicine, Surgery, Forensic Medicine and Toxicology, and Morbid Anatomy.

UNIVERSITY OF EDINBURGH.—The following is the official list of candidates who passed the Second Professional Examination in Medicine:—

John Anderson, *R. J. Ashton, Hugh Bennett, R. J. A. Berry, *J. W. Bone, H. J. M. Buist, W. M. Cairns, K. M. Cameron, J. J. W. Campbell, Charles Cochrane, R. P. Cockburn, D. B. Crerar, G. D. Darlington, Arthur Dennison, H. R. L. Davis, *C. J. W. Dixon, D. P. M. Farquharson, F. T. Foster, E. J. Fox, R. A. Fryer, E. B. Garland, P. F. Grant, Henry Goudie, Frederick Gourlay, G. C. Greaves, F. T. Griffin, T. A. Green, R. E. Harrold, H. H. Hearsey, G. E. Helme, H. M. Hewer, A. G. Horden, J. V. Hulme, John Joakim, J. M. M. Kay, C. B. Ker, Robert Lamb, M.A.; E. P. T. von Landsberg, H. E. Lee, R. E. Little, John Livingstone, R. M. Lyon, James MacBride, J. G. Macdonald, James Maclarlane, H. M. MacGill, Wakefield MacGill, T. G. M'Kellar, H. J. Mackenzie, H. V. M'Kenzie, John Maclaren, J. D. Maclean, W. B. Macleod, Charles Macmaster, C. B. Martin, H. F. Malabre, George Melville, J. Adie Menzies, A. S. Miller, Alexander Mitchell, T. W. Mitchell, E. C. Moore, C. A. Morgan, Robert Muir, J. A. Murison, John Newington, P. A. Nightingale, N. G. Noble, C. M. Ormsby, John Panton, Wm. Paul, E. R. Parry, R. L. Price, *Harry Rainy, J. L. Reed, E. H. Ridley, J. H. Roberts, J. C. Robertson, David Rorie, Robert Rosie, Wm. Sanders, Walter Sansom, P. W. Schmidt, John Sharp, William Simmers, F. M. T. Skae, Thomas Stodart, Archibald Stodart-Walker, Robert Strachan, Charles Stuart, *David Stuart, William Thyne, J. C. Tosswell, A. K. Thomson, L. J. Weatherbe, J. C. Whyte, George Wilson, O. R. M. Wood, James Younan, R. J. E. Young.

* With distinction.

CONJOINT SCHEME OF THE COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND.—The following gentlemen have passed the Third Professional Examination:—

N. George Cookman, E. Cosgrove, Henry M. Cullinan, R. D'Alton, S. W. Dawson, H. W. Devlin, T. G. Dillon, B. G. Elliott, E. G. Fenton, P. Flanagan, M. J. Hannan, A. R. Hudson, A. H. Jacob, G. W. Joyce, A. Ernest Keeble, S. Keogh, A. J. M'Munn, J. M'Kenzie, W. A. Murphy, A. W. M'Comiskey, L. T. Wheelan, G. F. Woodroffe, R. W. Wright, and R. S. Young.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following have been admitted Licentiates in Dental Surgery of the College:—

F. E. Garner, T. M. Howkins, E. Mawer, W. D. Quinn, F. Sheppard, and C. H. J. Williams.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—The library will be closed from August 1st to an early date in October.

NOTIFICATION.—The Camberwell Vestry has, it appears, followed St. Olave's Board of Works in expressing approval of the Compulsory Notification of Infectious Diseases Bill now before Parliament.

THE VACCINATION COMMISSION.—At the sitting of the Commission on Wednesday, there being a full attendance of members, Dr. Rauch, of Chicago, was examined.

CAVENDISH COLLEGE, CAMBRIDGE.—The Cloth-workers' Company has offered a scholarship of £30 a year, tenable at Cavendish College; and the Fishmongers' Company has made a grant of £50 to the same College.

PRACTICAL RECOGNITION OF POOR-LAW MEDICAL SERVICE.—The guardians of the Hoxne Union have granted Mr. C. G. Read, M.R.C.S., medical officer of the Stradbroke district, on his application, a superannuation allowance of £145 per annum. Mr. Read had served the union, in his capacity as medical officer, for upwards of forty years.

BENEVOLENT MEDICAL SOCIETY, KENT.—Mr. P. Purvis, M.R.C.S., of Blackheath, presided at the annual general meeting of this Society, held on July 10th, at Maidstone. The object of the Society is the assistance of medical men (being members) when in distress, and their widows and daughters, if required, and in other exceptional circumstances. The financial statement was satisfactory, and it was resolved that £330 should be appropriated for distribution amongst the several applicants for relief.

NATIONAL VETERINARY ASSOCIATION. — This Association held its seventh general meeting, on the 24th of July, in the Rooms of the Society of Arts. Professor W. Pritchard, the President, delivered his opening address, which chiefly dealt with the growth and great strides of the veterinary profession in recent years, of the causes assigned for which he referred to the example it had received from the sister profession. Professor E. Crookshank read a paper on Cowpox. A discussion then took place, and subsequently Mr. A. E. Macgillivray read a paper.

JUBILEE NURSES' INSTITUTE FOR WALES. — A meeting was recently held in the Council Chamber, Cardiff, with a view to forming a centre in Cardiff for Wales in connexion with the Queen Victoria Jubilee Institute for Nurses. It will be remembered that the Queen decided to devote £70,000 of the women's Jubilee offering to the promotion of district gratuitous nursing of the poor in their own homes. Accordingly this preliminary conference was held in order that the objects of the grant might be explained and the necessary steps taken to carry out the purposes of the grant. A provisional committee of six, with power to add to their number, was appointed, it being explained that the nurses would only visit the houses, not stay in them. This would in no way interfere with but rather help the infirmaries, for when the nurses saw cases becoming serious they would recommend patients to go to the infirmary.

Digitized by Google

CLAYTON HOSPITAL, WAKEFIELD.—At the annual meeting of the supporters of this institution, held recently, the report, which was adopted, showed that whilst the number of patients in each department had increased, there had been a considerable falling off in the revenue. The chairman referred to the distribution of recommendations, and said that more discernment ought to be used in giving them away.

COTTAGE HOSPITALS.—On July 27th a cottage hospital was opened at Falkirk. The cost of the premises has been about £1600. Mr. Joseph Peake, L.F.P.S.Glas., is medical officer.—A new hospital of the same class is being erected at Longton, Staffs., with thirty-eight beds.—The annual meeting of the Carnarvon Cottage Hospital was held a few days ago, at which the satisfactory announcement was made that the debt of £1302 had been almost cleared off.—An attempt is about to be made to establish a cottage hospital in Ashton-on-Mersey.

BRITISH DENTAL ASSOCIATION. — The annual general meeting of this Association will be held at the Royal Pavilion, Brighton, on Aug. 22nd, 23rd, and 24th. We understand tickets of admission may be obtained by any medical practitioner interested in the subjects which will come before the meeting. A discussion on Anæsthetics is on the programme, a subject which is likely to awaken considerable interest, as representatives from other countries will be present to describe the different methods adopted to produce anæsthesia.

ROYAL INFIRMARY, MANCHESTER.—The recently issued annual report for the past year records that 43,985 persons received assistance at this infirmary and its allied institutions at Cheadle and Monsall, of whom 4504 were in-patients, 1378 were sent to the Convalescent Hospital at Cheadle, 1960 were admitted at the Fever Hospital at Monsall, and 36,143 treated as out and home patients. The report remarks that a large proportion of the patients who presented themselves were well able to pay a part of the cost of their medicines, and should be required to contribute in this, or some other form, to the funds of the institution. The income had been £22,331, and the expenditure amounted to £30,387. The combined institutions provide 1000 beds.

SOCIETY FOR THE STUDY OF INEBRIETY.—On the invitation of the President and Council, Mr. Clark Bell, President of the Medico-Legal Society of New York, was entertained at a largely attended reception, on July 26th, in the rooms of the Medical Society of London. After refreshments, the President (Dr. Norman Kerr) moved a congratulatory resolution. Mr. Bell, in his reply, commented on the great advance in America in the scientific treatment of the insane and the inebriate, and dwelt on the urgent necessity for a reconstruction of our present unwise criminal treatment of inebriates, who should be dealt with as subjects of disease, instead of being punished as willing offenders. Short addresses were given by Dr. Walter Dickson, R.N., and others.

PROFICIENCY EXAMINATION FOR VOLUNTEER MEDICAL OFFICERS.—The following medical officers who have attended the lectures of the Volunteer Ambulance School of Instruction, given by Surgeon Walter Pearce, M.D., 20th Middlesex (Artists) Rifle Volunteers, on the subjects of the above examination, have obtained the Proficiency Certificate; under the new regulations this has to be obtained by all acting surgeons of the Volunteer force:—Surgeon-Majors Pocklington, 2nd V.B. East Surrey Regt.; T. Joyce, 2nd V.B. (the Buffs) East Kent Regt.; Culver James, H.A.C.; S. P. Smith, 1st V.B. Royal Fusiliers. Surgeons T. L. Gentles, 1st V.B. Derbyshire Regt.; O. M. White, 1st Tower Hamlets R.B.; W. D. Waterhouse and J. W. Jackson, 1st Tower Hamlets R.B.; L. Ogilvie, M.B., and G. Ogilvie, M.B., London Scottish R.V.; H. A. Desvœux, M.D., Queen's Westminster R.V.; H. F. Stokes, London Rifle Brigade; S. M. Moore, 2nd (South) Middlesex R.V.; E. J. Hunter, 3rd V.B. Hampshire Regt.; E. Stewart, M.D., Middlesex Yeomanry Cavalry; R. M. P. Low, 1st Middlesex E.V.; H. W. Roberts, 2nd V.B. (The Queen's Own) Royal West Kent Regt.; J. H. Walters, 1st V.B. the Royal Berkshire Regt.; C. Anol, 3rd V. (Kent) Brigade, Cinque Ports Division R.A.; W. Gandy, 2nd V.B. East Surrey Regt.; D. Playfair, M.B., 2nd (the Queen's Own), Royal West Kent Regt.; J F. Porter, 2nd V.B. East Yorkshire Regt.; R. H. Hodgson, Tower Hamlets E.V.; J. W. Davies, M.D., 3rd V.B., the South Wales Borderers. A new course of lectures for this examination will commence on Monday, Sept. 30th, at 4.30 P.M., at the headquarters of the Queen's Westminster R. V., Buckingham-gate. The details of army medical administration, equipment, and hygiene will be fully explained and illustrated, and arrangements will be made to suit the convenience of officers residing at a distance from London. Medical officers joining this class can also attend the lectures and drills for regimental stretcher bearers, which will be held at the headquarters of the Queen's Westminster R. V. and the London Scottish R. V., Buckingham-gate, and the 4th V. B., the Queen's Royal West Surrey Regiment, New-street, Kennington-park. The hon. sec. is R. Reginald Sleman, 7, St. Benet's-place, Gracechurch-street.

DERBY AND DERBYSHIRE NURSING AND SANITARY ASSOCIATION.—The twenty-fourth annual meeting of this Association was recently held, under the presidency of the Mayor. The report, which was carried unanimously, stated that during the year 419 nurses had been supplied to private families, as against 276 in the previous year, representing 1651 weeks of nursing, as against 1472. Air-pillows, bed-rests, and other sick-room appliances had been lent to 450 patients, and Bath chairs to 160. The work of the nurses had never been more satisfactory and reliable than during the past year. The financial position of the Association was also favourable.

THE DUFFERIN MATERNITY HOSPITAL, BURMA.—A large and influentially attended meeting was held at Government House on June 14th in support of this institution. Sir Charles Crosthwaite (Chief Commissioner of Burma) presided. The chairman stated that the hospital and training institution so far had been successful. During the first year 142 passed through the hospital, in the second year 228, and up to date 405 women had been treated in the hospital, and there had been 209 births. Twenty women had this year passed as nurses, and fourteen of these as midwives. The experimental stage of the work was passed, and it had become absolutely necessary that a suitable building should be provided. The present structure is a temporary one, and may have to be vacated at any time. The Central Committee of India had contributed 5000 rupees towards the Building Fund, and they themselves had set aside 5000 rupees for the same purpose.

PROVINCIAL HOSPITAL SATURDAY COLLECTIONS.—The West Bromwich District Hospital Saturday collection amounted this year to £1260 9*s.* 1*d.* The recent Saturday collection at Reading, on behalf of the Royal Berkshire Hospital, realised £361, an increase of £120 upon last year. The Maidenhead Saturday collection, on behalf of the Cottage Hospital, amounted to £60 7*s.* 5*d.*, or about £15 more than last year. The amount collected this year for the Birmingham Hospital Saturday Fund was £8658 19*s.* 1*d.*, of which £8300 has been divided amongst the local medical charities. The Liverpool Hospital Saturday collection this year amounted to £3206, showing an increase of about £302 on 1888. The annual demonstration at Stockton on behalf of the Stockton Hospital, held on the 21st ult., produced £54 5*s.* 4*d.* The total Hospital Saturday collections at Bolton for this year amount to £1482 11*s.* 11*d.*, an addition of £248 8*s.* 7*d.* on the previous year.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—The summer meeting of this Society will be held at Leeds on Thursday, August 15th, at 4.30 P.M., in the theatre of the medical school. The following papers will be read: "Notes on the Arrangement of the Lumbar and Sacral Nerves in a subject with six Lumbar Vertebræ," by Dr. Ambrose Birmingham; "Photography as an aid in Anatomical, Histological, and Embryological work," "On Nerve Terminations in the Thyroid Gland," and "On the Pyramidal Tracts of certain Rodents," by Dr. Alex. Fraser; "On the Cutaneous Nerves of the Trunk, with special reference to Herpes Zoster," by Drs. T. Wardrop Griffith and M. J. Oliver. Also various specimens will be exhibited. Members may, if they wish, send their specimens to Dr. T. Wardrop Griffith, secretary of the Anatomical Section of the British Medical Association Museum, Chemical Laboratory, Mechanics' Institute, Cookridge-street, Leeds, between August 1st and August 7th, and if the member is not present at the meeting the secretary will take charge of them.

THE INFIRMARY, ARBROATH. — The forty-fifth annual report of this infirmary shows that 176 patients were treated during the past year, of whom 120 had been cured, 25 relieved, 15 had died, and 10 still remained under treatment. The financial position was not satisfactory. The revenue had been less than the previous year by £141 8*s.* 5*d.*, and there was a slight increase in the expenditure The endowment fund now amounts to £9856 9*s.* 10*d.* During the year a convalescent house had been purchased near Colliston, for which contributions amounting to £1500 had been received.

MEDICAL NOTES IN PARLIAMENT.

An Annual Census.

IN the House of Lords, on Friday, July 26th, Earl Fortescue called the attention of their lordships to the desirability of having a cheap and simple annual census of the population in addition to the ordinary decennial one.—Lord Balfour of Burleigh did not view the proposition with favour. An annual census, he said, must necessarily be costly, as the process adopted in the decennial census would have to be followed in an annual one. So frequent, however, had been the applications to the Local Government Board on the subject that he (Lord Balfour) had resolved to appoint a departmental committee to consider the desirability of entertaining the idea.

The Hospitals of London.

On Monday, July 29th, Lord Sandhurst presented a petition, signed by members of the medical profession and by others, also on behalf of various medical charitable institutions, praying for inquiry in regard to the financial and general management and the common organisation of medical institutions, endowed and voluntary, and in regard to the administration of Poor-law institutions for the aid of the sick in the metropolis; and moved that the prayer of such petition should be agreed to. His lordship said this was not the first time that the subject had been considered. Various medical committees had considered the whole or portions of the subject. No action, however, had been taken by the hospitals. Failing these, the information had been amassed by the Charity Organisation Society. The medical relief in the metropolis might be classed under two heads—charity and Poor-law charities. There were 11 general hospitals with schools, and 8 general hospitals without schools; 67 special hospitals; 26 free dispensaries; 35 provident dispensaries; 13 part pay dispensaries; and five surgical appliance societies. The number of in-patients was 76,898, and out-patients 1,470,398. The total income was £696,258, and the total expenditure was £723,021. The beds unoccupied were about 2000 in number. To these must be added 27 Poor-law infirmaries, with 11,900 beds, and £336,200 expenditure; 44 Poor-law dispensaries, with 114,980 out-patients, and £19,980 expenditure; 8 infectious hospitals, with 2760 beds, and £129,313 expenditure. The total was as follows:—239 institutions—in-patients, 122,047; out-patients, 1,585,353; total expenditure, £1,208,523; total income, £1,197,477, in the year 1887. Having described the position of the endowed hospitals and the function of those having schools attached, the speaker referred to special hospitals. He said, of the special hospitals, some were special in treatment, but nearly all for special diseases. He was anxious to be moderate, but he must and would say what he thought, and what those who were with him thought. The origin and management of some of the special hospitals had been such as to cause suspicion, where suspicions existed, as to the conduct of hospitals as a whole. They were not unfrequently started for private advantage by those who wished to make themselves consulting physicians to them, some for speculative purposes, and in neither case considering the public welfare nor the advance of science. They were generally started, as to funds, more or less by some philanthropist, and on that support failing they were thrown on the public. There were no schools, no advance of science, and the management left much to be desired. Owing to the small number of beds the administration must be costly. He then quoted the opinion of Sir Andrew Clark on the character of these institutions, as expressed in a speech he delivered at the Mansion House in June last in aid of the Hospital Sunday Fund, and concluded with a reference to a paper by Mr. Michelli on hospital extravagance.—Viscount Cranbrook followed, and promised on the part of the Cabinet that the case for inquiry should be considered, and that next session he might be able to announce to his noble friend what course the Government proposed to take. He could assure his noble friend that the matter would receive the attention of the Government.—The Earl of Kimberley said that the committee on which he sat last session expressed a desire that the Government should consider the whole matter. An attempt had been made at amalgamation, but had failed owing to the difficulties in the way. Poor-law infirmaries had become so important as to occupy a very great place in the treatment of the sick. The whole subject was a very large and complicated one, and at the present time he could only say that he was glad to hear that the Government were directing their attention to it.

Muzzling of Dogs.

In the House of Commons, on Friday, July 26th, Mr. Lawson asked the Home Secretary if the London County Council had taken any action with regard to the muzzling order, and, if not, whether the police authorities would act on their own authority.—Mr. Matthews replied to the first question in the negative. In answer to the second question, he said the Commissioner of Police would act only on the terms prescribed by the Act.

Royal Barracks, Dublin.

In answer to Mr. Hanbury, Mr. Stanhope said he did not think his information warranted him in believing that fever at the Royal Barracks was daily increasing. Nevertheless there had been a new outbreak of enteric fever there, and orders had been given that the building should be temporarily vacated and the troops placed under canvas.

Merchant Shipping Acts Amendment Bill.

The amendments to this Bill were agreed to, and the Bill was read a third time.

Lunacy.

On Monday, July 29th, in answer to Mr. Corbet, the Home Secretary said that the provisions of the Lunacy Acts had been fully carried out in the case of Mr. Miers. Mr. Matthews also, in answer to the same questioner, said: I am informed by the Commissioners in Lunacy that in their opinion the annual increase in the number of registered lunatics, idiots, and persons of unsound mind, as shown in the returns, appears to be mainly due to the accumulation of chronic pauper cases. It has not been established that there is any material annual increase of fresh cases of insanity out of proportion to the increase of population. With regard to cases of illegal detention, it is the practice of the Commissioners to investigate all clues, and to take proceedings against persons found to be infringing the law. Prosecutions have usually been followed by the discovery of fresh cases previously unreported.

Passenger Ships and Hospital Accommodation.

In reply to Mr. O'Keefe, Sir M. Hicks-Beach said the ships of the Royal Mail Steampacket Company carrying passengers to the West Indies and South America from this country do not carry from the United Kingdom more than fifty passengers as defined by the Passenger Acts. They are therefore not passenger ships under those Acts, and no other ships are required by law to provide hospital accommodation. Space is always provided on board the ships of the Royal Mail Steampacket Company, which can be turned into hospitals in the event of an epidemic breaking out. The cabin where an infectious patient is lying is always surrounded by blankets steeped in a solution of carbolic acid or other powerful disinfectant. The Board of Trade has no power to enforce regulations for securing health on board passenger steamers unless they are also passenger ships under the Passenger Acts.

Lunacy Acts Amendment Bill.

On the order of the day for the consideration of this Bill as amended by the Standing Committee, Mr. Mac Innes rose to move that the Bill be recommitted in respect of a new clause as to the removal of pauper lunatics to their places of settlement. This amendment was, however, by leave withdrawn, and the motion to consider the Bill as amended was agreed to.—On the motion of Mr. Matthews, a new clause was agreed to providing that a county court judge or magistrate should not be required to exercise any powers under the Act which would interfere with the exercise of his ordinary jurisdiction.—Mr. John Ellis moved a new clause to provide that there should be exhibited in every asylum a printed notice setting forth the right of every private patient to have any letter written by him forwarded to its address, or within twenty-four hours submitted to a visiting Commissioner or Visitor or else forwarded to the Commissioners or the Masters in Lunacy; also the right to request a private interview with a visiting Commissioner or Visitor on the occasion of any visit made to the asylum. Dr. Farquharson said that the Grand Committee had rejected the clause after full discussion. According to the best medical testimony the exhibition of such notices would imperil the recovery of patients by unsettling their minds. After remarks by several members, Sir W. Foster expressed his objections to the clause mainly on medical grounds. Its effect would be to produce on the minds of the patients a continual irritation leading to outbursts of excitement, which would hinder their cure. The clause had first originated at a time when there was a "scare" in the public mind, it being supposed that persons were wrongfully shut up in those asylums. That scare had been shown to be groundless. Ultimately the clause, with some verbal amendments, was added to the Bill The 20th Clause was omitted, and, on the motion of Mr. Matthews, a subsection was added to Clause 21 making it sufficient if a certificate of lunacy in a workhouse under the section is signed within three months of the passing of the Act, and enabling one certificate to cover more than one patient, and another to Clause 34, enabling persons in charge of a single patient to add others in the same home under special circumstances. Amendments in Clause 40 were also agreed to providing for reports of the condition of pauper lunatics taken charge of by relatives, and the remuneration of medical officers making such reports, as were likewise a series of amendments in Clause 52, extending the powers of management in the case of lunatics so found by inquisition in England to their estates in Scotland or Ireland without further inquisition.—After some further amendments, the report was agreed to; and, on the motion of Mr. Matthews, the Bill was read a third time.

Universities (Scotland) Bill.

On Wednesday, the 31st ult., on the motion for the third reading of this Bill, Mr. Wallace took occasion to express his belief that the sum of £42,000, which the Bill appropriated to university educational purposes, was altogether insufficient to carry out the reforms which were expected. Mr. Goschen, in reply, maintained that Parliament had dealt very liberally with the Scotch universities, and he thought that considerable economy might be effected by a revision of the scale of payment to professors. The Bill was read a third time.

Infectious Diseases Notification Bill.

Mr. Ritchie moved the second reading of this Bill, and explained that its object was to prevent the spread of infectious diseases by insuring that on their outbreak the medical officer of health and the inspector of nuisances should visit the premises affected and have power to isolate the patient or require his removal to a hospital. The diseases which it was proposed to include in the Bill were small-pox, cholera, diphtheria, erysipelas, scarlatina, typhoid, and relapsing fever. The Bill also contained provision for the inclusion, on an emergency, of some diseases other than those mentioned. The Government proposed that the Bill should be compulsory for London, but outside it should be optional for the local authorities to adopt the Act by resolution. If it were found, however, that the local authorities were slow to adopt the Act, it might be necessary for Parliament to consider whether it should not be made compulsory.—Sir W. Foster objected to medical men being asked to notify the existence of disease, on the ground that it would weaken the confidential relations between medical men and their patients. Anything that came to the knowledge of a medical man in the practice of his profession was practically an inviolable secret. He feared that the result of the present proposal might be to induce people to treat infectious cases at home without the intervention of a medical man. He thought the notification should be made by the householder or guardian, and not by the medical man.—Mr. Ritchie, in reply to Mr. Sexton, said there would be no objection to extending the Bill to Ireland. — Several speakers followed and expressed general approval of the Bill, whilst criticising some of its details. The Bill was read a second time without division

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BRETTINGHAM, C. E. SEPPINGS, L.F.P.S. Glas., L.A.H. Dub., Medical Officer and Public Vaccinator to the Stogumber Division of the Williton Union, has been appointed Medical Officer of Health for the Eastern Division of the Williton Union.

CHAMBERS, A. B., M.D., M.Ch., L.M. Irel., has been appointed Medical Officer of the Stapleford District, Shardlow Union.

COPE, ALBERT E., M.B., B.S. Durh., has been appointed House Surgeon to the Royal Infirmary, Newcastle-on-Tyne.

CRIBB, C. H., has been reappointed Public Analyst for the Strand Board of Works.

GREENWOOD, E. C., L.R.C.P. Lond., M.R.C.S., has been appointed Public Vaccinator for the Parish of St. Marylebone.

GRIFFITH, P. S., L.R.C.P. & S.Ed., has been appointed Medical Officer of the Pelham District of the Bishop Stortford Union, and of the No. 4 District, Saffron Walden Union.

HOPKINS, J. W., L.R.C.P. Edin., M.R.C.S., has been reappointed Medical Officer of the First District, Leeds Union.

LEIGH, RANDLE, B.Sc. Lond., M.R.C.S., has been appointed Demonstrator of Physiology in University College, Liverpool, vice F. C. Larkin, appointed Assistant Lecturer.

MANTON, JOHN ALBERT, M.R.C.S., L.R.C.P. Lond., has been appointed Demonstrator of Anatomy to the Sheffield School of Medicine, and also Medical Officer to the S.E. District of the Sheffield Union.

PIESSE, CHAS. H., M.R.C.S., L.S.A., has been reappointed Public Analyst for Fulham.

PIETERSEN, JAMES F. G., M.R.C.S., L.R.C.P.L., of Bannatyne, Etchingham-park, Finchley, has been appointed Divisional Surgeon to the S Division of the Metropolitan Police, vice Dr. Hunter Barron, deceased.

POGSON, J. W. B., M.B., B.S., M.R.C.S., has been appointed House Surgeon at the Durham County Hospital.

QUEELY, ST. GEORGE J. E., L.S.A. Lond. & Dub., Government Medical Officer, Maytown District, has been reappointed Surgeon to the Palmer Hospital, Queensland.

ROBB, J. TAYLOR, M.D., C.M., has been appointed Third Attending Medical Officer to the Pimlico-road Free Dispensary.

SLOMAN, FREDK., M.R.C.S., L.S.A., has been appointed Assistant Medical Officer of the Infirmary, parish of St. Leonard, Shoreditch.

STEPHENSON, S. H. A., M.B., C.M. Edin., L.S.A. Lond., has been appointed Medical Officer in charge of Ophthalmic cases at the Central London District Schools, Hanwell.

ERRATUM.—The announcement last week of the appointment of Mr. S. P. Hosegood as Assistant Medical Officer to the Hamlet of Mile-end Old Town Infirmary was inserted in error

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

CHELMSFORD AND MALDON RURAL SANITARY AUTHORITIES.—To the Clerk of the Joint Committee, 90, High-street, Chelmsford.—Medical Officer of Health for the Combined Rural Sanitary Districts of Chelmsford and Maldon, Essex. Salary £600 per annum.

CORNWALL COUNTY ASYLUM, Bodmin.—Junior Assistant Medical Officer. Salary £100 the first year, £110 the second year, and afterwards £120 a year, with board, lodging, washing, and attendance.

COVENTRY AND WARWICKSHIRE HOSPITAL, Hay-lane, Coventry.—House Surgeon. Salary £100 per annum, with board (exclusive of beer, wine, and spirits), lodging, and attendance.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W.—Registrar and Chloroformist. Salary 50 guineas per annum, non-resident.

NORFOLK AND NORWICH HOSPITAL, Norwich.—Dental Surgeon (Honorary).

NORTH STAFFORDSHIRE INFIRMARY, Hartshill.—Physician or Medical Officer.

QUEEN'S HOSPITAL, Birmingham.—Physician to Out-patients. For three years. Annual honorarium £50.

RIPON DISPENSARY AND COTTAGE HOSPITAL, Ripon.—Resident House Surgeon and Dispenser. Salary £70 per annum, with board and lodging.

ROYAL MASONIC INSTITUTION, Wood-green, N.—Medical Officer. Salary £80 per annum. Surgical and medical appliances (drugs included) are provided by the institution.

SALISBURY INFIRMARY.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

ASHWORTH.—On July 27th, at Halstead, Essex, the wife of J. Henry Ashworth, M.R.C.P.Ed., of a daughter.

KENYON.—On July 25th, at Hooton Pagnell, near Doncaster, the wife of G. Herbert Kenyon, M.D., of a son.

TIMS.—On July 26th, at Lupus-street, St. George's Square, S.W., the wife of H. W. Marett Tims, M.B., of a daughter.

WHEELER.—On July 22nd, at Pembridge-gardens, W., the wife of John Wheeler, M.D., M.Ch., M.A.O., of a daughter.

WILLIAMSON.—On July 26th, at Eldon-square, Newcastle-on-Tyne, the wife of G. E. Williamson, M.A., F.R.C.S., of a son.

MARRIAGES.

BLACK—SMIRTHWAITE.—On July 30th, at St. James' Church, Burnley, by the Rev. J. M. Dorset Owen, M.A., Vicar of Holy Trinity, assisted by the Rev. Ben Winfield, B.A., J. Lyell Black, M.B., to Nell, widow of the late Dr. Smirthwaite, of Burnley.

BOYD—TOMS.—On July 25th, at Acton, Stanley Boyd, M.B., F.R.C.S., of Harley-street, to Florence Nightingale Toms, M.D., third daughter of the late William Tucker Toms, of Chard, Somerset.

HORDER—STUBBS.—On July 24th, at St. James's, Pentonville, Edward George Horder, M.D., of Pakhoi, China, C.M.S., to Eliza Caroline Stubbs, of Mecklenburgh-square.

ROBERTS—KETT.—On Aug. 1st, at St. Paul's, Cambridge, by the Rev. R. J. Roberts, father of the bridegroom, assisted by the Rev. H. B. Budham, the Rev. F. J. Dickinson, and the Rev. E. F. Plume, Reginald John Roberts, B.A., M.B., B.C. (Cantab.), of Haselrig, Lowestoft, to Catharine Sarah, daughter of George Kett, Esq., of Wymondham House, Cambridge.

SCOTT—ANDERSON.—On July 25th, at St. Stephen's Church, C.-on-M., Manchester, by the Rev. J. Hill Banham, M.A., Vicar of Keysoe, assisted by the Rev. T. Edelston, William E. Sawers Scott, M.D., Fallowfield, Manchester, younger son of A. D. Scott, Victoria Park, to Margaret Euphemia, eldest daughter of John T. Anderson, Swinton-avenue, Manchester.

STEVENS—GACE.—On July 31st, at St. Catharine's Church, Southbourne-on-Sea, by the Rev. L. R. Whigham, Vicar, Arthur Blundell Stevens, M.A., M.B., B.Ch. Oxon, son of the late William Stevens, of Springfield, Tulse-hill, London, to Ada Mary, second daughter of Joseph Gace, of Southbourne-on-Sea.

DEATHS.

BEVISS.—On June 30th, at Pinetown, Natal, Charles Beviss, M.D., M.R.C.S., aged 49.

DESSÉ.—On June 18th, 1889, in the Island of Barbadoes, West Indies, Ethelrid Dessé, F.R.C.S., M.B., M.D.Lond., &c., also M.D.Utrecht, son of the late Anthony Dessé, of Surinam, Dutch Guiana, aged 46 years and 9 months.

EWING.—On July 27th, at Alderney-street, S.W., John Ewing, Deputy Surgeon-General, aged 73.

POLLARD.—On July 28th, at his residence, 123, Lavender-hill, Wandsworth, Clement Pollard, M.R.C.P., L.R.C.S. Edin., aged 40.

THOMPSON.—On June 22nd, at Pensarn, Thomas Thompson, M.R.C.S., L.S.A., Surgeon-Major of the 1st Volunteer Battalion Royal Warwickshire Regiment.

WISE.—On July 23rd, at Thornton, Beulah-hill, Upper Norwood, Thomas Alexander Wise, M.D., late of the Bengal Medical Service, in his 88th year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE MORALITY OF THE COLLEGE OF SURGEONS WITHDRAWING THE MEMBERSHIP FOR ADVERTISING, &c.

Fairplay, in a letter too long for publication, raises the question of the right of the Council to withdraw the diploma of one of its Members for advertising and the adoption of such methods of obtaining practice as the pressure of the times seems to suggest. He argues that the membership of the College is a personal property, duly worked for and paid for, and unwithdrawable. The simple answer to this is that it is granted on conditions of professional conduct, the violation of which subjects the owner to the jurisdiction of the Council. We cannot admit that any pressure of the times justifies unprofessional practices, or that, in the long run, the public would benefit by allowing such practices to be followed with impunity.

Shenfield.—Without a full report of the evidence of the coroner we are unable to form a final opinion upon the point raised in our correspondent's letter. As at present informed, we are at a loss to understand how the disease in question would be a legal or moral excuse for the offence. Of course it may be alleged that the renal mischief had led to deterioration of brain tissue, and so to mental power. If this were the case, we opine there would have been strong collateral testimony to support the contention in the shape of other symptoms of cerebral aberration.

Mr. Biddle.—We regret that we are unable to comply with the suggestion, as the type of the article is distributed.

THE VACCINE VESICLE.

To the Editors of THE LANCET.

SIRS,—I was public vaccinator at Brighton for twenty years, during which time I vaccinated upon an average 500 a year. My two colleagues vaccinated more than I yearly. We all agreed that in propagating the vaccine vesicle you could produce nothing else. The same opinion has been expressed to me by public vaccinators whom I have questioned on the subject. This was triumphantly confirmed by the late Mr. Badcock's experiments, for, after forty years, Mr. Badcock produced the very same thing that Jenner discovered, the vesicle having passed through the human constitution more than 2000 times and remained unaltered. Only let a medical man take his vaccine according to Jenner's directions from a plump vaccine vesicle, and not drain the vesicle too much, and I defy him to introduce any other disease. This vaccine, which is the germ of a very mild small-pox, can produce itself and nothing else. An acorn cannot produce a beech tree, neither can a beech nut produce an oak; but convince a man against his will, he's of the same opinion still. To the anti-vaccinationist I would say, "Neither would he be convinced, though one rose from the dead."

I am, Sirs, your obedient servant,

Sidney Cottage, Newhaven, Sussex. D. RICHARDSON.

THE BACILLUS ANTHRACIS.

THAT the germs of charbon pass from the mother to the fœtus is a pathological fact of which the French investigators, MM. Chamberland and Straus, claim to be the original discoverers. The communication in which they announced their discovery was made on Dec. 16th, 1882, to the Biological Society of Paris, and it was published on the 23rd of the same month. Professor Perroncito, however, the well-known Piedmontese pathologist, asserts that it is he to whom priority in the discovery is due—his paper announcing the fact having been read before the Accademia di Medicina di Torino on Dec. 15th, 1882, and published in the *Gazzetta Piemontese* of the day following. Like many similar discoveries, that of the transmission of the bacillus anthracis from mother to fœtus may well have been made independently and simultaneously, coincidences of the kind becoming every day more probable as workers in the same field, under the same conditions, become more and more numerous.

C. W. S. S.—Roscoe: Lessons in Elementary Chemistry, Inorganic and Organic (London, Macmillan and Co., *4s. 6d.*).

"THE INTER-RELATIONS OF SPECIFIC MORBID POISONS."

To the Editors of THE LANCET.

SIRS,—The question of the affinities and antagonisms between different specific diseases and their power of modifying each other either favourably or otherwise, which formed the subject of discussion recently in your columns, is one which no doubt is worthy of considerable attention. It is a satisfaction to know that we have advanced a stage since Hunter's day, and that the majority of us no longer doubt that two specific fevers may coexist in the same person. On reference to my notes of cases of contagious and infectious diseases I observe instances of scarlet fever or small-pox, the former disease and rubeola, pertussis, and scarlet fever coexisting in the same patient, and no evidence that the condition increased the patient's risk, in fact rather the opposite. The very interesting question as to whether or not the phthisical condition predisposes to or confers an immunity against other specific diseases is most difficult to answer, but there is some reason for thinking that it is so in the case of certain members of the class. With reference to the other point mentioned in your article, it appears not improbable that just as in the case of the specific fevers coexisting, similarly the poisons of syphilis and phthisis may do so. It is thought by some that the victims of phthisis do not contract enteric fever. It would be interesting to know if they possess a like immunity from typhus. I fancy those who have had an extended experience would be inclined to take a contrary view. Our knowledge of the inter-relations of specific diseases is so very limited that any facts bearing on the question are of value in the etiology and prognosis of disease.—I am, Sirs, yours faithfully,

Barking, March, 27th, 1889. SAMUEL LEE.

GUTSCH'S FIELD LAZARETTO AND OPERATION-ROOM.

THE gold medal given by the Empress Augusta for the best field lazaretto and operation-room has been gained by Dr. B. Gutsch of Karlsruhe, and the mechanism in question is now exhibited in the private sanatorium of the inventor. The problem of meeting all requirements of a clinical and operative ambulance on the field of battle has been solved by it, with a minimum of weight and bulk Twenty beds, provided with every requisite, and an operation-room, including a dispensary, make up the whole, which can be transported by a three-horse waggon to the most distant points. An ordinary goods truck, indeed, can convey three of the Gutsch lazarettos—i.e., sixty beds. Economy of space is effected by the contrivance that almost every article of furniture can be made to fulfil a double function, while the concentrated form of the medicaments admits of their being contained in a chest of very moderate dimensions.

L.R.C.P.Ed., &c., Registered.—Our correspondent is well entitled to his fee, and, we should think, would have his claim allowed in a court of law.

A LITERARY HERBALIST.

To the Editors of THE LANCET.

SIRS,—The enclosed letter may be of interest to some of your readers. It was brought to me by a patient, a fisherman, on his return from Grimsby. The absence of a diagnosis and of any information as to the treatment adopted are perhaps the most noteworthy points. I may add that the patient was fully under the impression that he had been under the care of a legally qualified medical man.—Yours obediently,

W. J. ERNELY SUMPTER, M.R.C.S., &c.

Sheringham, Norfolk, July 30th, 1889.

"—— Herb Store, —— Street, ——, Grimsby.

"GENTLEMEN,—DEAR SIR,—I thought it fit for me to write you a line as to the case of (H—— M——) as to give you satisfaction poor man I must add he was suffering from extreme pain and by my being so well known in the neighbourhood he was advised to consult me which he did so and by my treatment of him obtained relief for a short period and then came on again when he really felt obliged to return homewards, for he knew by not being able to fulfil his duties he would not be required with his fellow workmen. I saw him first on June 18th and last time on 25th and thought really it would be best for him to come and see you to attend him thought you would really do your best for him hoping you will succeed in doing the same

"I remain yours Respbly

"—— ——."

WELL-INSPIRED PHILANTHROPY.

A CITIZEN OF LEIPSIC, possessed of ample means, and of the still rarer gift of knowing how to make them useful to his fellow-man, has just presented to the medical relief fund of that city and its neighbourhood two extensive estates in the Saxon Erzgebirge, specially purchased by him as places to which the poor labourer or artisan, recovering from illness, may be sent for the completion of his cure. Both estates—the one near the Schneeberg, the other near the Schwarzenberg—are finely situated in a healthful, well-wooded, well-watered region, and have been pronounced, on the highest medical authority, to be admirably adapted for their purpose. The donor has made it a condition of his gift that his name be kept undivulged.

Epileptic is referred to the Charities Register and Digest (published by Longmans) and our advertising columns for the information he seeks.

"MEDICAL ADVICE FREE: MEDICINE 2D. PER BOTTLE!"

To the Editors of THE LANCET.

SIRS,—Evidently "Pro bono Publico" made a slip of his pen when, in your last issue, he wrote: "What we object to solely is, not the formation of 'non-pauperising dispensaries,' but the gross and shameless advertising," &c. Now, as one of the forty complainants to the Irish College of Physicians of the "shameless advertising" of the "Clapham Dispensary"—*2d.* per bottle—proprietors, permit me to say, on behalf of myself and others who have signed the complaint, that we have an uncompromising objection to all dispensaries not "formed" in the usual orthodox way. The so-called "dispensaries" of private individuals we consider to have been at the root of the most disreputable form of advertising known to the profession; and even those of the Metropolitan Provident Medical Association have been advertised in a manner deserving the keenest censure of every respectable practitioner. Such "dispensaries" are but "cheap-jack" drug shops, and their evils to the profession and to the public have been exposed in your columns, and especially in those of some of your contemporaries, over and over again.

I am, Sirs, faithfully yours,

Stockwell-road, July 29th, 1889. R. H. S. CARPENTER.

To the Editors of THE LANCET.

SIRS,—Will you kindly insert this statement in your next issue? I spent ten weeks in the house of the doctor whose conduct has been recently criticised in your columns, and left there April 30th. To my certain knowledge, the handbills alluded to were not, and are not, placed under every knocker and into every letter-box in the whole district," as "Pro bono Publico" states in your issue of to-day. The dispensary in question is supported by the doctor who instituted it and her private friends. It is distinctly a charity, and is not "made to pay." Twopence per bottle does not even cover the cost of the actual drugs, much less defray the expenses of the house where the dispensary is carried on, or remunerate the women physicians who give their services. This is self-evident.

I ask you to be so courteous as to publish my letter, because I dislike the so-called "handbills" as much as any medical man in the neighbourhood; but in justice their distribution cannot be called "touting." I enclose my card, not for publication, but as a guarantee of good faith.

I am, Sirs, yours faithfully,

July 27th, 1889. M. L. S.

PUBLIC SPEAKING.

Beta asks for the names of any books which would afford help in the art of public speaking. Mr. Bright in one of his speeches mentions such a book.

HOW MANY TEETH TO MAKE A BITE?

To the Editors of THE LANCET.

SIRS,—I shall feel obliged for your opinion on the following case.

In a scuffle A was bitten by B on the arm. A asked me to examine his arm. I found four teeth marks of one jaw over the deltoid muscle, but no mark over the other jaw. I was followed into the witness box by another practitioner, who swore that it was a physical impossibility for B to bite, as he had no upper teeth. I saw B's mouth afterwards, and found that he had a full set of teeth in the lower jaw, with the exception of one of the lateral incisors gone, the others coming together to partly fill up the vacancy, and so causing the teeth to be rather widely separated, which corresponded exactly with the marks on A's arm. There was only one tooth in the upper jaw in front—viz., a lateral incisor, which had been loose for years. My opinion is that the loose tooth would give, and the jaw would impinge against the arm, while the lower teeth would cause the marks described. Is it a physical impossibility for B to bite? A had his coat on when the affair occurred.

I am, Sirs, yours faithfully,

July, 1889. A SUBSCRIBER.

*** Where all the teeth are lost in the upper jaw the lower teeth almost invariably bite against the gum, and this may from use in mastication become hard and dense, just like the upper gum of ruminants, in whom the upper incisors are normally absent. There is nothing strange therefore in severe injury resulting from the bite of such a person. The presence of the one incisor would make but little difference, but would be rather in the way than otherwise.—ED. L.

Dr. Geo. B. Beale.—Medical Institute, Edmund-street, Birmingham.

Astonished has forgotten to enclose his card.

CLINICAL ESTIMATION OF THE SPECIFIC GRAVITY OF THE BLOOD.

DR. LLOYD JONES reminds us that the ingenious method of estimating the specific gravity of blood in small quantities referred to in our last issue (p. 183) was introduced by Prof. Roy of Cambridge, and that he (Dr. Lloyd Jones) employed a modification of Prof. Roy's plan.

Dr. Mott.—We shall be pleased to receive the paper.

THE THERAPEUTIC ACTION OF SENNA PODS.

To the Editors of THE LANCET.

SIRS,—If Dr. Macfarlane will turn to page 448 of Woodville's Medical Botany he will find an interesting account of the uses of senna pods. I quote a few words: "Mesue likewise seems to prefer the pod to the leaves, as being a more efficacious cathartic; but the fact is the contrary, for it purges less powerfully than the leaf, though it has the advantage of seldom griping the bowels, and of being without that nauseous bitterness which the leaves are known to possess."—Yours truly,

July 27th, 1889. A. ST. CLAIR BUXTON.

Valedictory Address,

DELIVERED AT THE

PRESENTATION OF PRIZES AT THE ARMY MEDICAL SCHOOL AT NETLEY,

On August 2nd, 1889,

BY SIR DYCE DUCKWORTH, M.D.,

PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL, FELLOW AND TREASURER OF THE ROYAL COLLEGE OF PHYSICIANS.

GENTLEMEN,—It affords me much gratification to come amongst you and to bear a part in the ceremonial of to-day, and my thanks are due to the courtesy of my good friend the Director-General of your department, and the Senate of the Army Medical School, for the honour they do me in inviting me on this occasion. This is not my first visit to Netley. In 1866 I and a small party of friends had a narrow escape from a watery grave in front of this Royal Hospital, being all but capsized in a small sailing-boat. We landed here in a very drenched condition, and were at once taken care of by that great and good man whose name is, and ever will be, a talisman in this place, Dr. Edmund Parkes. I here and then first made his acquaintance, and I am proud to remember that I knew him in the flesh. About two years ago I had the honour of being present at a prize-giving ceremonial in this theatre, when my friend Sir Thomas Crawford directed your department. From my earliest student days I have always had a high regard for Netley, and for the excellent work done here both by its professors and pupils. I say without hesitation that this school has been one of the most valuable centres of medical, surgical, and hygienic training in the empire, and its benefits have radiated hence to all quarters of the globe, and been fruitful in numberless instances, as well to the civil as to the military communities they have reached. This is surely a strong assertion to make on behalf of any institution, but it cannot, I believe, be denied in respect of Netley. This school has been a model for others, and has excited admiration on the part of all who have appreciated its merits. When, therefore, I learned some time ago that it was in contemplation to curtail the advantages of this school, I confess that I was astonished. I could only account for such a proposal as the outcome of a spirit which is too prevalent in the present day—a spirit which is satisfied with nothing as it is, and which seeks to uproot and disturb everything for the mere sake of change, and in response to a restless phase of unphilosophical and purely experimental radicalism. I had thought that this school was rather undermanned, and needed, if anything, further development of its powers for usefulness. And now, I understand, the proposal is that those who would naturally come here to be trained for service in India should receive their training in that country. I know a good deal about students of medicine, having had to do with them for nearly thirty years. I have been in India, and know something of the conditions of life in that great dependency; and I form the opinion that such a plan as is proposed will prove little less than a failure. India is not a country in which Europeans can readily pursue with zeal and profit any line of study. I am well aware that this assertion can be instantly challenged, and the fruitful labours of men like Norman Chevers, Fayrer, Vandyke Carter, Lewis, Ewart, Cunningham, with many others in your department alone, be adduced in contradiction to it. While accepting this, I yet hold that the conditions under which the average young candidate would receive his training in India would be unfavourable, and the results distinctly less satisfactory than those which can be attained in this school.

Lest I should appear to be unmindful of the excellent work done in the universities and medical colleges of India, I would add that I fully appreciate this, and often wonder how so many of my countrymen can toil so untiringly and successfully under tropical conditions. I could better understand the necessity for the change proposed were it shown, which it has not been, that the training given here is inadequate, or that it could be conducted by better teachers, and with more complete equipment in any part of India. I can only express the hope, therefore, that your successors may long frequent these walls and find higher advantages, if possible, than you have done.

Since I was last here you have suffered two great losses in the persons of Dr. de Chaumont and Dr. David Boyes Smith. They were both friends and fellow-graduates of mine. It is not for me, here and now, to try to gauge the full measure of the loss to this school of two such men. I may add my humble testimony to the worth of each of them, and recall the solid scientific attainments of the one, recognised the world over wherever the subject of public health is studied; and remind you of the modesty, high-mindedness, and heroism of the other, whose merits were best known to those who knew him best, but whose noble spirit will long inspire his pupils and his brother officers. The examples and influence of men of such parts as these constitute enduring traditions for the school they served, and I would bid you to emulate their conduct and moral loftiness.

I must now offer you my congratulations on having completed your term of study here, and in particular add my commendation to those who have won honours in the school. Netley honours are not easy to secure; they can only testify to solid and good work, and I cannot doubt that here, as elsewhere, the officers who gain prizes will probably be amongst the best at a later period of their career. I say, advisedly, *amongst* the best, for nowhere is "the race always to the swift"; and I confess to some degree of shyness coming over me when I find myself in the presence of the man who carries off too many honours. I am rather afraid of that man. He is not always quite human, and in my experience he is not always the biggest man of his batch twenty years afterwards. In these terrible days of competition, a man must strike out vigorously, and put his back into any work he wishes to excel in; no harm comes of that. But there is a grasping spirit abroad which sets itself to gain everything, and goes so straightly to the goal that it loses a great deal of humanity and sweetness in the process. The professional prize-taker picks up his medals and books, and sits down again; but he is often rather alone with himself in his own little world, and may perchance have failed to cultivate and cement friendships, to develop his muscles and his agility, and in short to be quite the good "all-round" fellow he ought to be. This is a shocking heresy to utter at such a time, and in such a place, but I believe you would like me to say to you what I really think of these matters.

I have certain knowledge of the fact that competition, as such, has done much to injure the *camaraderie* in all the services it has been introduced into, and I am old-fashioned enough to believe in the *invincible* power of *camaraderie*, especially in our fighting departments. Hence, I have no doubt that some of the "passmen" of to-day will in the future do good and true service, and I suppose it is not beyond the bounds of probability that even in the person of one of them now before me I may be addressing a director-general of the future.

I congratulate you on taking service under the Crown. Most of you, I believe, will shortly proceed to India. Some of you are what I may term "seasoned" officers, and as you are the seniors, my remarks are for you in the first instance. The fact that you are here is itself much to your credit, and also shows wisdom on the part of the heads of the department. I can well understand your position. I had the honour to be an assistant surgeon in H.M. Navy at an early period of my career. I therefore know something of the delights of discipline, and of being in a position to do what one is told, and not what one likes. In the first few years of your service it is hardly possible for you to see much practice or to bear much responsibility. With increasing rank these come. But you naturally wish to furbish up your knowledge, and to know more and more of your professional business, to learn the newest methods of treatment, and to take part in carrying them out. Here you have every means for this at your disposal. Your presence here is also valuable for your juniors; but it has also, I hope, entailed upon you the responsibility of setting them high examples, and of attracting them to their duties and to the service they have chosen.

To those of you who will soon begin work in India I may well bid God speed. Your sphere will be full of novelty and interest in that great country. You will see the British soldier at his best, and take your respective parts in

Digitized by Google

that most marvellous accomplishment, the holding of the vast dependency of India, with its teeming millions, in the hands of a comparatively few thousands of trained troops. You, as part of that army, begin well, for you go out at an age when it is proper for an European to begin life in the tropics. It is a very different matter, as I fear you will soon learn, for an immature man to begin a man's work in India. I have had to do with five of the great railways in India for twenty-three years, and have, therefore, had some experience of the climatic and other influences of that country on Europeans of all ages. That experience compels me to affirm—and I do so in all seriousness, for it is a grave matter—that it is wrong to send a young man to do hard work in India until he is twenty-three years of age. My hospital experience has long since taught me that a large number of the recruits for the Queen's regiments enlist at the ages of sixteen and seventeen, and I have known lads of seventeen landed in India and reckoned as efficient soldiers. I have also known them come back again within eighteen months, used up and ruined in health. My experience, on the other hand, goes to show that after the age of twenty-three a man can do man's work in the tropics, and commonly ceases to be as vulnerable as he would have been in the six previous years. Those are very critical years in any young man's life. You will remember, for one thing, that the epiphyses of the bones are not firmly ossified till the age of twenty-two, and if development is not completed in the osseous system, we may fairly assume that it is still imperfect in other systems. In any case, the power of resisting endemic fever, solar influence, and enteric fever is greatly increased in the critical years I have mentioned, while at the same time there is often an attainment of greater moral stability. I say nothing as to the way in which such a waste of military power should be met. I know there are difficulties in securing and retaining matured soldiers, but your business and duty as guardians of the health of our troops compel you to make these mistakes known, and to persist in pointing out faults which come officially under your cognisance. Do you suppose that if these facts were known and appreciated by the tax-paying public, that the present wasteful system of sending to many immature soldiers to the tropics would be continued? You must never cry Peace when there is no peace.

India is the best country wherein to learn many things that you will require to know in military medical practice. All is real and "work-a-day," and you will find fewer "make-believes" there than at home. I suppose it is not too much to assert that but for our Indian military experience, our fighting capacity as a nation would be vastly inferior to that now possessed by us; and in using the expression fighting capacity of an army, I distinctly include the Medical Department, which always has formed, and will continue to form, one of the most important units of any aggressive or defensive force. Your department is probably not less perplexed with grievances than any other administrative one. I forbear to strike any notes to-day which may jar on the harmony which should prevail on such an occasion as brings us together, but I know that one *quæstio vexata* which much concerns you has lately been discussed before a Commission, and with the results of its deliberation we are not yet familiar. The points immediately concerned in this important question of rank relate, as I believe, exclusively to military matters, and hence the mass of the civilian profession is hardly qualified to form an opinion that should carry weight with it on such a subject. (Your brethren in civil life, however, are quite competent to appreciate such an indignity as had lately to be submitted to by some of your seniors in India, when the *insignia* of their position as members of the Viceroy's medical staff were taken from them. I trust to hear that this matter will soon be rectified.) The question I take to be important, because it concerns not only the comfort and peace of mind of the individual officers concerned, but also the harmonious working of our military forces, and, what is of greater moment, the sanitary welfare of the army. You have always sought and found, in any legitimate efforts, support from the profession at large, and this will assuredly not fail you now, if it should be needed. But I would utter a warning against agitations, and any but constitutional means of remedying grievances, if they exist. When I remind you that you are soldiers, I have in view the especial virtues of such men—viz., discipline and loyalty,—and, above all, their happy freedom from the petty thraldom of politics.

What the country has to look for in medico-military matters is perfect efficiency, and the endeavour to secure that knows, and shall know, no end. The question arises here whether the modern conditions of your department secure the best medical attendance for the officers, rank and file, and all persons belonging to an individual regiment. I understand that your arrangements are adapted with a view to war time, and not to meet the wants of a state of peace. As, happily, our troops are more engaged in keeping the peace than in making war, it is a fair question to ask whether the old system of regimental surgeons is rightly done away with. I have been led to form the opinion that it was a mistake to detach medical officers from, at all events, some continuity of service with regiments, and I venture to state that I think it would be well if one or two surgeons were definitely attached for a term of years to each regiment. The advantages of this plan are at once obvious, and I conceive that it might be carried out without any violent dislocation of existing arrangements. In war time surgeons are attached to regiments, but they then do not know the men, and the men do not know the surgeon. It is impossible to work both in quarters and in the field on a Procrustean system, and we must not look for guidance in this matter to the military services of other countries, inasmuch as no other army is called on for such varied duties and experiences as our own.

I regret to find that the military authorities are beginning to call on civilian members of the profession to do military medical work for them. I fail to see the necessity of such a proceeding. There can be, and there ought to be, no difficulty in finding trained officers to do this work, and if such are ready to act, I consider it unfair to pass them by.

I believe that young men who now enter either the Army Medical Department or the Indian branch of it are to be congratulated on the careers they have selected. The "plums" of private practice in civil life are now none too many. Our profession is, in fact, overstocked, and the strife to gain a living in it is very great. Competition is now so keen that some of our humbler brethren are compelled to undertake duties entailing anxiety and serious responsibility for the most miserable remuneration. In times of commercial depression young men are wont to resort to our profession, and so, of late years, our ranks have been preternaturally filled. Happily, this source of supply has now ceased to run. In my opinion, the most wholesome checks on over-admission to our ranks will be found in the institution of higher entrance examinations, and in the prolongation of the curriculum of study from four to a minimum of five years, the last year being mainly devoted to clinical work. Amongst the peculiar advantages of your position are, that you see much of the world, and may thus become in the best sense men of the world; that you have leisure for higher mental cultivation if you will avail yourselves of it; and that after twenty years' service you can retire with a pension, still young men, and take up your profession in civil life, with excellent chances of advancement. Not many men at the age of forty-two can make a fresh start in life with an equipment so solid in all respects as yours may be at that time. I maintain that with such prospects the career you have chosen is a very desirable one, and should attract some of the choicest men from every great school of medicine.

Of your teachers here it would ill become me to speak. The names of many of them, past and present, are household words in our profession. I know that your department as a whole venerates them, and you best of all know the worth of those who have so lately guided your studies. For myself, I can only say that I should count myself happy to sit at the feet of Maclean, of Longmore, and of Aitken, and to imbibe not only the lore they could infuse into me, but also some of the sterling qualities and graces that they bear aloft so well. It is for you to run with, and carry on to others, the torches of knowledge which they have put into your hands.

I take this opportunity, which seldom comes to one in my position, of making a few remarks before military surgeons on the subject of the abolition of the Contagious Diseases Acts. I regret to think that you will soon have sad experience of the unwisdom of that measure. You and I are young enough to hope to see those Acts restored to their place on the statute book. That they were ever repealed testifies to a degree the ignorance and folly that we, as a people, should be ashamed of. We can but regret and pity the want of resolution and firmness in those who control the affairs of the nation, and who find themselves charged with the

Digitized by Google

power to govern, but unable to fulfil the office of a government, yielding to sensational clamour, and letting loose again a plague that we had in great measure controlled. Many hard words have been uttered in this noisome controversy; but remember that "hard words break no bones." You who agree with me, and who have the best right to your opinions, know, or soon will know, too well how grievous is the havoc wrought by the undoing of this legislation. We care not for any amount of obloquy that may be uttered against us for denouncing this folly, and we must not cease to declaim vigorously against it. It is almost grotesque to watch the undulations and inconsistencies of public opinion in respect of contagious diseases. A few days since the inhabitants of London were scared by the discovery of a solitary, and practically harmless, leper in the community; but the five millions of the metropolis are quite unconcerned in the presence of perhaps twenty thousand or more persons suffering from all forms of distinctly contagious syphilis. That is of no consequence, I suppose. Not only for the navy and the army, but for every city, town, and community, should a Contagious Diseases Act be passed. That is the logical claim forced on us as physicians and guardians of the public health, and we urge it no less in our capacity both as Christian men and loyal citizens. It is very satisfactory to learn that the new local governing body in Malta have at once restored these Acts, and are enforcing them with much benefit to the garrison and the town of Valetta.

Gentlemen, it is one of the penalties of venturing to think and act for yourself that you are often alone and exposed to obloquy and misapprehension. It is not a popular course to follow, but popularity is, after all, a very poor thing. Our duty in all the concerns of life is to do what we believe to be right, and to submit to any consequences. I have detained you too long. In conclusion I have only to express my best wishes for the career of each one of you. Your position is already a very enviable one. You have a splendid sphere of duty. You will go out to see England beyond the seas. You will come in contact with some of the best men who are doing their best work. You will aid your country in maintaining in vigour her right to govern other nations; you will, I feel sure, carry everywhere with you the traditions, not only of this great school, but of your respective universities and medical colleges; you will dispense to others the blessings you have learned to value in our common mother country; you will always think and act as educated British gentlemen; and you will, I hope, earn fresh laurels for medicine, and especially for that branch of it you are now so well-fitted to represent. Let me urge you in particular to cultivate firmness and dependability of character, qualities which are quite consistent with the graces of modesty, tact, and good temper. Success in any calling is as much, if not more, a matter of personality as of great accomplishments. In your profession, above all, duty has the first claim, and all else must bend before it. "He who serves best afterwards rules best." And you will, I hope, not learn to ignore or despise sentiment. I have been speaking of sentiment already, but I then alluded to mawkish and hysterical sentiment. None of that, if you please. But in matters military, medical, and otherwise, there are, and ever will be, true and noble sentiments. Yes, gentlemen, there is a sentiment in a button, in a badge, in a monogram, and in a facing; there is a sentiment in a reminiscence; you know it already, you will soon know it better; and any one of these, or of a hundred other like things, may come in a moment to nerve you to face an ugly duty, to shun an evil course, to set a bold example, or, if need be, even to meet the death-stroke of a hero. *Vale!* And to each one of you I add, "*quod felix, faustumque sit!*"

EPSOM COLLEGE. — Mr. France has presented another Female Scholarship at St. Anne's School to the Council of Epsom College. This is the sixth scholarship he has purchased. Mr. France is doing good with both hands. With the one he gives a large sum of money to a most deserving institution, with the other he enables the members of the council of the College to give in perpetuity a first-rate education, free of all charge, to six girls, the orphan daughters of medical men.—Lucas, Mair, Norman, Barron, Griffiths, and Hardcastle, pupils of Epsom College, have all passed in the first Division at the Matriculation examination of the University of London.

Remarks
ON
PROFESSOR BURDON SANDERSON'S THEORY OF ASPHYXIA.

BY GEORGE JOHNSON, M.D., F.R.S.

IN my recently published Essay on Asphyxia I have suggested as a probable explanation of Dr. Burdon Sanderson's statement that both sides of the heart are equally distended immediately after death from apnœa, that such a result might be brought about by a dose of curara sufficiently in excess to paralyse the vaso-motor nerves and the arterioles.

Since the publication of the essay in question I have read Dr. Sanderson's Croonian lecture on the "Influence exerted by the Movements of Respiration on the Circulation of the Blood,"[1] and also the abstract of the same lecture in the Proceedings of the Royal Society, 1867. In the lecture, at p. 586, the results of experiments with woorara[2] upon four dogs are described, and it is stated that "in the two last experiments the quantity used corresponded to one-tenth of a gramme of solid woorara."

Dr. Rutherford, in his lecture on the Circulation,[3] says that "the dose of curara should be just sufficient to paralyse the voluntary muscles; if the dose be excessive, the vaso-motor nerves are also paralysed. The amount given should be six milligrammes for a rabbit in winter and three milligrammes in summer; twelve milligrammes for a small dog and eighteen milligrammes for a large one."

Dr. Sanderson's dose of one-tenth of a gramme, which is, in other words, one hundred milligrammes, was more than five times the amount which Dr. Rutherford employs for a large dog. It is not, therefore, surprising that the results obtained by these two experimenters should be contradictory.

Dr. Sanderson attributes the increased systemic arterial pressure which occurs during the first stage of apnœa to the violent respiratory efforts. He says:[4] "It may be concluded that the extraordinary elevation of arterial pressure which has been long known to occur during the second minute in death from apnœa is not due, as was supposed by Dr. Alison and Dr. John Ried, to obstruction of the capillary vessels, either pulmonary or systemic, but to the violence of the respiratory efforts. The cavity of the chest being closed, the force exercised by the respiratory muscles expresses itself in variations of tension of the enclosed air, which are communicated through the intra-thoracic arteries to those outside of the chest, producing those violent oscillations of the dynamometer which have been referred to. In support of this inference, it was shown that in an animal under the influence of woorara (when all respiratory movement ceases while those of the heart are unaffected), the process of apnœa is not only of greater duration, but is not attended with any of those greater disturbances of the circulation which have been hitherto attributed to capillary obstruction. The gradual extinction of the force of the contraction of the heart is indicated by a slow and uninterrupted subsidence of the arterial pressure."

Now, in justice to Dr. Reid, I maintain that no one can have carefully read his most interesting and instructive paper on the "Order of Succession in which the Vital Actions are arrested in Asphyxia" without perceiving that he clearly distinguished between the steady increase of arterial pressure resulting from the impeded transit of unaerated blood through the minute systemic vessels and the greater paroxysmal increase which he correctly attributed to the violent respiratory movements and struggles of the animal.[5]

If Dr. Reid's experiments left any doubt as to the existence of increased arterial pressure easily distinguishable from that caused by the struggles of the animal, Mr. Erichsen's[6] carefully conducted experiments upon animals in which muscular movements were annihilated by pithing should suffice to convince the most sceptical. In

[1] Philosophical Transactions, 1867. [2] Another name for curara.

Digitized by Google

one experiment, after artificial respiration had been suspended, Mr. Erichsen found that the mercury in the dynamometer, which had stood at from 3½ in. to 4 in., rose to from 5¾ in. to 6½ in., at which it stood for about two minutes. In another experiment the mercury rose from between 3½ in. and 4½ in. to 6½ in. and 6¾ in. In a third experiment the mercury rose 2 in. or 2½ in. above the level at which it stood when inflation of the lungs was suspended.

These experiments should have sufficed to place beyond all controversy the accuracy of Dr. Reid's original statement, that, contrary to his own preconceived idea, there is, for a period of about two minutes after respiration has ceased, an increase of systemic arterial tension and pressure, the result of an impediment to the passage of unaerated blood through the terminal systemic vessels.

Dr. Rutherford's experiments upon a dog paralysed by a moderate dose of curara and with the chest and pericardium opened, have shown that with the increased systemic arterial tension during the first stage of apnœa, the pressure within the left cavities of the heart is so great as to distend them to an inordinate degree. Now that we have proof of the excessive dose of curara employed by Dr. Sanderson, we can understand the discrepancy between his results and those of other observers. The vaso-motor nerves, both pulmonary and systemic, being paralysed, the regulating and controlling power of the arterioles is annihilated, there is no increase of pressure in the systemic arterioles, therefore no distension of the left cavities of the heart. "The process of apnœa is of greater duration," for the reason that the pulmonary arterioles being paralysed, have lost the power of arresting the flow of blood through the lungs. The apnœal process is therefore prolonged, as it is in newly born animals with a patulous foramen ovale, which allows the blood to pass directly from the right to the left side of the heart, and thus to evade the controlling influence of the pulmonary arterioles. The amount of blood on the two sides of the heart after death is therefore equal, or nearly so; and, as Dr. Sanderson says, "the gradual extinction of the force of the contraction of the heart is indicated by a slow and uninterrupted subsidence of the arterial pressure."

The vaso-motor paralysis resulting from an over-dose of curara is so far instructive that it affords confirmatory evidence that the early systemic and the later pulmonic obstruction during the progress of apnœa are results of contraction of the arterioles. For this indirect proof of the influence which the unparalysed arterioles exert upon the circulation during the successive stages of apnœa we are indebted to Dr. Sanderson's experiments with excessive doses of curara; but, unfortunately, the entirely exceptional condition thus induced has led Dr. Sanderson to contradict the statements of Dr. Alison, Dr. John Reid, and many other accurate observers, and to attempt the revival of the antiquated theory of Bichat, which assumes that the immediate cause of death from apnœa (asphyxia) is not the arrest of the pulmonary circulation, but cardiac paralysis, consequent on the circulation of venous blood through the coronary vessels—a theory which, in my essay on asphyxia, I have proved to be inconsistent with indisputable facts. Before the publication of my essay, I had carefully studied Dr. Sanderson's chapter on Respiration in the "Handbook for the Physiological Laboratory," but I had not read his Croonian lecture at the Royal Society, and therefore, not knowing what dose of curara he had employed, I could only surmise that his exceptional results were due to vaso-motor paralysis caused by excessive doses of the poison. That this is the true and complete explanation of the facts has now, I think, been conclusively proved.

SYMPATHY WITH A FALSELY-ACCUSED SURGEON.—On the 30th ult., a dinner was given at Edmonton, attended by fifty gentlemen (many of whom were professional friends), to Mr. W. Jones, L.R.C.P., L.R.C.S.Edin., of Upper Edmonton, as an expression of sympathy on the trying circumstances to which he had been subjected by a recent prosecution on a cruel and grave charge preferred against him, and tried at the Central Criminal Court, of which he was completely acquitted, and left the court without a stain upon his character. A fund is being raised to defray the legal expenses incurred by Mr. Jones in meeting the groundless charge, and the present result of the effort is given in another column (page 300).

A CASE OF

PAROXYSMAL HÆMOGLOBINURIA WITH EXPERIMENTAL OBSERVATIONS AND REMARKS.[1]

BY JOHN S. BRISTOWE, M.D.,
AND
S. MONCKTON COPEMAN, M.A., M.B.

[*Note.*—The following paper has been written by myself and in the first person, mainly because I found it more convenient to write it in that form. It is essentially, however, the joint production of Dr. Copeman and myself. I was anxious that an experimental investigation of the case should be made, and asked Dr. Copeman to carry out my views. The nature of the experiments to be performed, and the object for which they were performed, were matters of constant discussion between us. But the actual experiments (the account of which forms the great bulk of the paper, and nearly all that is interesting in it) were performed by Dr. Copeman alone. The concluding remarks represent our joint opinions.—J. S. B.]

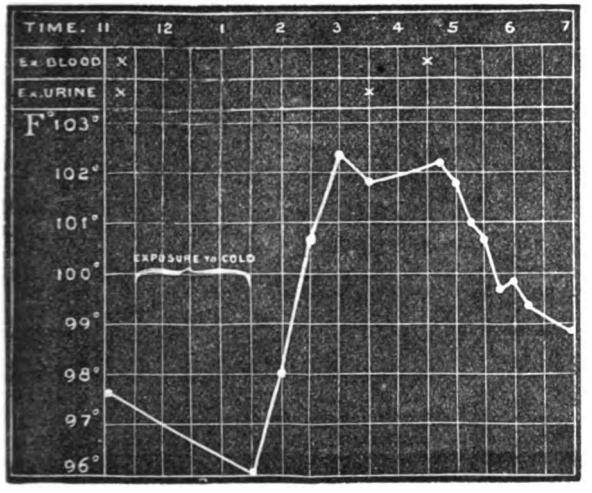
James G——, an omnibus conductor, aged forty-one, was admitted under my care on Jan. 3rd. He had had syphilis twenty years previously, followed by a secondary eruption, but otherwise had had good health down to January, 1886. He had never had rheumatism or ague. He is a native of London. In the winter of 1885-86 he began to suffer from coldness of the extremities and from occasional "dying" of the fingers; and in January he was attacked with what was supposed to be frost-bite of the middle three toes of the right foot and all the toes of the left. He was treated for this affection in the London Hospital, where he remained about six weeks. During this time he lost the nails of the affected toes. He remained fairly well during the following summer; but during the winter months of 1886-87 he suffered, whenever he was exposed to cold, from coldness of the extremities, often attended with "dying" of the fingers, shivering, and headache, and followed by the discharge of thick, porter-like urine. He complained also of pain or difficulty in swallowing, and was often told that he was becoming jaundiced. In each succeeding summer he enjoyed good health; in each succeeding winter his malady recurred. Dr. Acland sent him into the hospital just as an attack was passing off.

The patient was a fairly well-nourished man, with a pale sallow complexion, but some rosiness of cheeks, due to persistent capillary enlargement. The sclerotics were slightly yellow. There was no evidence of disease either in the thoracic or in the abdominal organs. His tongue was clean; his appetite good; his bowels confined; his pulse 60, regular; his temperature normal. His urine had a specific gravity of 1018, was dark-coloured, clear, acid, contained a little albumen, and gave a blue colour with guaiacum and ozonised ether. The next day it was normal.

Excepting that the man remained somewhat anæmic and sallow, that when washing in cold water his fingers (mainly the second, third, and fourth) were apt to "die," and that he occasionally suffered from uneasiness after food and from nausea, he continued for the next ten days in good health. The equable temperature of the ward evidently agreed with him. Instead, however, of discharging him, and thus ensuring for him the frequent recurrence of his attacks, I determined, with his sanction, to keep him in the hospital for some time, and to perform a few experiments upon him, with the object of investigating the nature of his malady. As his clinical history in the hospital is practically only a record of these experiments, conducted by my friend Dr. Copeman, I will limit my notes of his case to them almost exclusively.

EXP. 1 (Jan. 14th).—He went, well wrapped up, between 10 and 11 A.M., for a three-quarters of an hour's walk on the hospital terrace. The morning was not very cold, but on his return he was cold and bluish, and shivered for about an hour, even though he sat over a warm fire. His hands generally were livid, and seemed somewhat swollen, and the second, third, and fourth fingers were cold and white. His feet also were very cold, but to the eye presented nothing

[1] Read before the Medical Society of London, April 29th, 1889.



Digitized by Google

remarkable. His throat felt swollen, and it was painful to swallow; and he had a feeling of "pins and needles" in the tip of his tongue. He lost his appetite during the day, and consequently took no dinner. At 12 his temperature had risen to 101°, at 4 it was 100·2°, and at 8 in the evening 98°. The urine passed before his exposure had a specific gravity of 1013, was pale, clear, and free from albumen; that passed two hours after his exposure had a specific gravity of 1020, was of a dark reddish-brown colour, depositing an abundant sediment, highly albuminous and acid, and presented all the usual chemical and microscopic characters observed in cases of hæmoglobinuria. The evening's urine was the same in quality, but contained considerably less hæmoglobin; and that passed in the course of the night still presented slight traces of blood-colouring matter. The next day he was in his usual health; but his blood, examined with the microscope, showed little tendency in the corpuscles to form rouleaux, and these bodies to be generally crenated or otherwise misshapen.

EXP. 2 (Jan. 17th).—The patient went out on to the terrace at 9.30 A.M., and remained out until 11.30. The morning was not cold, and, although on his return to the ward he looked chilly, he did not shiver or feel ill. Nevertheless, the temperature had risen to 100° by 2.30 P.M., and he had a marked attack of hæmoglobinuria. The sample of urine passed two hours and a half after his return was acid, had a specific gravity of 1024, and contained a large quantity of hæmoglobin; that passed in the evening had a specific gravity of 1010, was acid, contained albumen, had a distinct red tinge, and gave the guaiacum reaction. A drop of blood was removed from the finger late in the evening and gave the following results: "Examination with the hæmocytometer showed that, although the colour of the blood did not appear to be greatly lessened, the number of corpuscles was very small, there being only about 2,760,000 in the cubic millimetre, instead of about 5,000,000, the normal number. The colour of the individual corpuscles was quite up to the normal, but there was much variety in shape and size, some having almost twice the diameter of others, and there was only a slight attempt at the formation of rouleaux. The blood-platelets were increased in number, and here and there, floating in the liquor sanguinis, were irregular granular masses of pigment, probably hæmatin. The specific gravity of the blood was rather low, being 1047."

EXP. 3 (Jan. 23rd).—The patient went out for a walk at 11.30 A.M. and remained out till 1.30 P.M. The day was

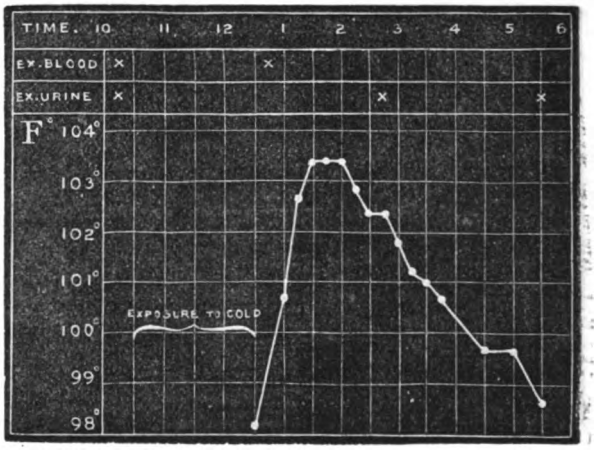


CHART 1.

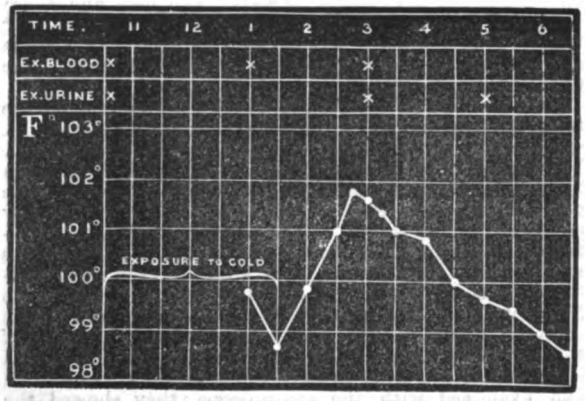
mild and rather foggy, and, so far as his feelings were concerned, the exposure had no injurious influence over him. He did not shiver. His temperature before going out and on his return was subnormal. At 2 P.M. it was still only 98°. At 2.30 P.M., however, it was 100·6°; at 3 P.M. 102·4°; and at 4.45 P.M. still 102·4°. After this it gradually fell, being at 7 P.M. 98·8°, and at 8 P.M. 98·2°. The patient's urine before going out had a specific gravity of 1029, was acid, and free from albumen and blood. The next specimen, passed at 3.30 P.M., was of specific gravity 1024, acid, of the colour of dark-brown sherry, and contained hæmoglobin. A specimen passed at 10 P.M. was perfectly normal, and had a specific gravity of 1013. The blood was examined both before and after the walk, and the following is the report concerning it: "Before exercise it was noticed that the patient did not seem nearly so anæmic as he was at the time of the last observation, and this was borne out by the fact that the corpuscles, as estimated by the hæmocytometer, amounted to 3,665,000 in the cubic millimetre. The corpuscles did not form perfect rouleaux, and varied somewhat in size; but their colour appeared to be normal. At 4.30 P.M. the blood was again examined. The number of corpuscles in a cubic millimetre had fallen to 2,970,000. There was no attempt at the formation of rouleaux, and many of the corpuscles no longer retained their circular form. Floating in the plasma were seen masses of amorphous hæmatin, and here and there small colourless crystals, with pointed ends, resembling the proteid crystals described by Charcot. The specific gravity of the blood had fallen about 5 degrees. (See Chart 1.)

EXP. 4 (Feb. 5th).—The patient took a walk on the terrace from 10.30 A.M. till 12.20. The morning was cold. A specimen of urine passed before exposure was normal. The blood also was examined, and found to contain 3,612,500 red corpuscles in the cubic millimetre. Before going out his temperature was subnormal. Immediately on his return it was 98·2°, and he had a rigor. The temperature then rapidly rose, and by 1.30 P.M. attained its maximum of 103·4°, at which it stood for the next half-hour. It then slowly fell, and had reached the normal at 5 30 P.M. At 2 45 P.M. the first specimen of urine after his exposure was passed, and at 5.30 P.M. another. Both of these were of a dark reddish-brown colour and typical specimens of the urine of hæmoglobinuria. When diluted and examined with the spectroscope, they showed the bands characteristic of acid hæmatin. The next specimen passed was unfortunately lost; while a yet later one gave no bands when examined spectroscopically. The blood examined after exposure contained only 2,930,000 red corpuscles per cubic millimetre. The hæmoglobin power of its individual corpuscles, which before exposure seemed normal, appeared afterwards to be somewhat, though very slightly, lessened. The plasma was slightly tinted, and granular masses of hæmatin were seen floating in it. After the lapse of some hours minute crystals of hæmoglobin appeared in the blood, which had been mounted for microscopic observation. On the 11th (six days later) the blood was again examined, when the red corpuscles were found

CHART 2.



to have risen to 3,540,000 per cubic millimetre. (See Chart 2.)

EXP. 5 (Feb. 15th).—The patient went out for a walk from 10.30 A.M. until nearly 1 P.M. The day was not cold, and the results were less marked than usual. The temperature and the urine were normal before the experiment, and the blood had a specific gravity of 1051⅞ and 3,270,000 corpuscles in the cubic centimetre, which bodies had their natural colour and shape, though varying much in size, some having twice the diameter of others. At 12.55 he was somewhat chilly, and his temperature 99·7°; the blood had a specific gravity of 1050⅜; the number of red corpuscles had fallen to 2,970,000 per cubic millimetre; their consistency had become impaired, as was shown by the abnormal shapes.

Digitized by Google

of many; and here and there were reddish-brown granular masses of hæmatin. At 3 P.M., at which time his temperature was 101·6°, the corpuscles had further fallen to 2,890,000. Specimens of urine passed at 3 and 5 P.M. respectively presented the usual character, and, as on former occasions, gave evidence of the presence of acid hæmatin in addition to hæmoglobin A third specimen passed at 9 P.M., when his temperature had fallen to 97 6°, presented a slight reddish-yellow tinge and no deposit; but it gave the guaiacum reaction; and, on spectroscopic examination of a layer half an inch in thickness, revealed no bands; but on similar examination of a layer two inches thick, two faint

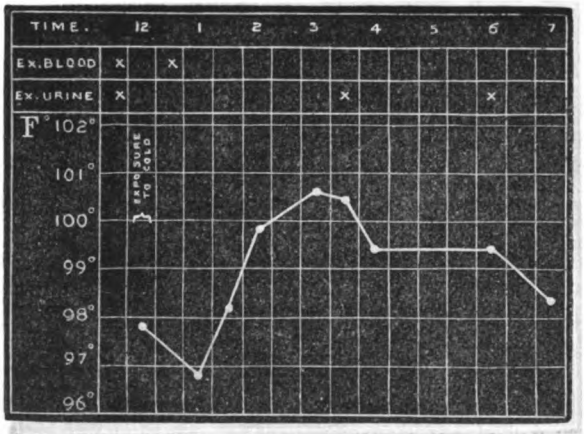


CHART 3.

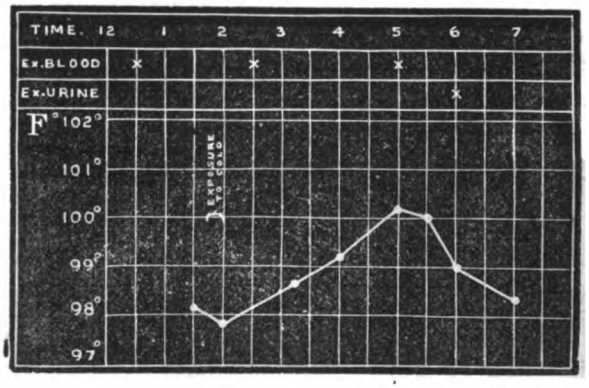
bands, apparently of oxy-hæmoglobin, were seen. The temperature on this occasion began to rise a little before 2 P.M.; it attained its highest point, 101·8°, by 2.45 P.M., and had fallen to 99° by 6 P.M. On Feb. 19th (four days later) the blood-corpuscles had risen to 3,450,000 in the cubic millimetre, and the hæmoglobin power was nearly normal. (See Chart 3.)

EXP. 6 (March 2nd).—At noon the patient placed his hands in iced water, and kept them there for about ten minutes. The hands became white, "dead," and he had a slight rigor. At 12.30 they were mottled, white and red, and still felt cold to the touch. His temperature before immersion of the hands was 97·8°. At 1 o'clock it had sunk to 96·8°. From 3 P.M. to 3 30 P.M. it lay between

CHART 4.

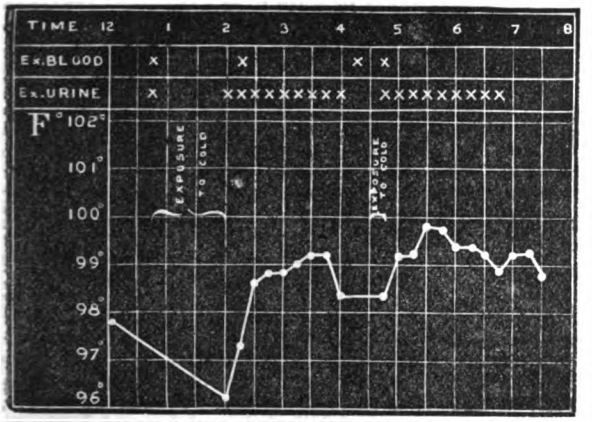


100° and 101°; and by 7 P.M it had become normal. The blood, examined before the experiment, contained 3,765,000 red corpuscles in the cubic millimetre, and its hæmoglobin power was 39 per cent. of normal. A little after 12.30, the corpuscles had fallen to 3,636 000, the percentage of hæmoglobin remaining unaltered. The specimens of urine passed during the day were examined the following morning. Specimen 1, passed at 3 30 P.M., when his temperature was 100·4°, had a specific gravity of 1014, was acid, of a fairly deep reddish-brown hue, and presented a very slight deposit, which showed under the microscope a large quantity of amorphous pigment and a few white corpuscles, but no red corpuscles or oxalates. It contained one-sixth of albumen. The spectroscope showed the bands of acid hæmatin. Specimen 2, passed at 6 P.M., when his temperature was 99·4°, had a specific gravity of 1012, was acid, of a clear straw colour, with a rather darkly-coloured deposit of mucus, in which were found a few granules and leucocytes. The guaiacum test gave a faint blue colour, but no bands were seen on spectroscopic examination. The third specimen, passed at 7.30 P.M., was clear, acid, sp. gr. 1010, and was without deposit, but gave the guaiacum reaction. Specimen 6, passed at 9 P.M., was clear, almost colourless, sp. gr. 1007, acid, and without reaction to guaiacum. (See Chart 4.)

EXP. 7 (March 2nd) —In the evening of the same day, at 7.30 P.M., an elastic band was fastened round the base of one finger, which was then immersed in iced water for a quarter of an hour, after which a drop of blood was removed from the finger and examined under the microscope. There was no attempt at the formation of rouleaux by the red corpuscles, which had nearly all lost their normal shape. Here and there three or four appeared to have become fused together; and some were almost completely colourless from loss of their hæmoglobin, while the surrounding plasma was deeply tinged with pink. The blood taken at the same time from one of his other fingers was in what, for him, may be termed the normal condition. A similar experiment performed on a healthy person caused no obvious change in the blood of the ligatured and cooled finger.[2]

EXP. 8 (March 7th) —It was objected to the last experiment but one—that in which the patient's hands were immersed in cold water—that the hæmoglobinuria might have been due not so much to the experiment as to the fact that (the day being cold) he was exposed to the general influence of cold in going from the ward to the physiological laboratory. It was determined, therefore, that the experiment should be repeated, the patient remaining all the time in the ward. At 12.30 P.M. the blood was examined, when it was found that the red corpuscles numbered 3,433,300 in the cubic millimetre, and the hæmoglobin power was 36 per cent. Fair rouleaux were formed, and the corpuscles were well shaped, though of various sizes. At 1.45 he again placed his hands in iced water. They were not kept immersed quite so long as on the former

CHART 5.



occasion. The day was warm. On being taken out of the water the hands were mottled and felt very cold. His temperature was normal at the time of the experiment. At 2 P.M. it was 97 8°, from which time it slowly rose, until at 5 P.M. it had attained its maximum, 100·2°. It had become normal by 7 P.M. At 2.30 the blood was re-examined. The red corpuscles had then fallen to 2,984,000, while the hæmoglobin power had only fallen by 1°, or at most 2°. No rouleaux were formed, but some abnormally shaped and decolourised corpuscles were seen. At this time the patient complained of pain across the loins, and later in the afternoon of difficulty in swallowing. Laryngeal inspection revealed nothing amiss, with the exception that the epiglottis was very anæmic. At 5 P.M. the blood was once more examined. The red corpuscles had been to a great extent replaced, and now numbered 3,366,000 in the cubic millimetre, but amorphous pigment was still seen in the plasma. The first urine after the experiment was passed at 6 P.M. It was of a brown-red colour, without sediment, and gave with the spectroscope the bands of acid hæmatin. A second specimen, passed a few hours later, presented no bands, but gave a faint guaiacum reaction. The third specimen was normal. (See Chart 5.)

[2] Ehrlich and Boas have both performed similar experiments, tending to show that the injurious action of cold is purely local.

Digitized by Google

EXP. 9 (March 18th).—On this day the experiment was made with the special object of determining the condition of the urine at short intervals. At 12.45, at which time his temperature was 97·8° and his urine normal, he went for a walk on the terrace, and was out until 2 P.M. The day was warm, the temperature in the shade being 52·5°. On his return to the ward, his temperature, pulse-rate, and respiration-rate were taken every quarter of an hour, and the urine was passed and examined at the same intervals. The temperature rose only very slightly, and the urine at no time presented any trace of blood-colouring matter, but in place of it contained a small quantity of albumen. His blood before he went out displayed 3,710,000 red corpuscles per cubic millimetre, hæmoglobin power 45 per cent., and

CHART 6.

specific gravity 1051; the red corpuscles formed poor rouleaux, and were of various sizes, but well-shaped. The blood on his return from his walk presented 3,440,000 corpuscles in the cubic millimetre, its hæmoglobin capacity was 42 per cent., and its specific gravity 1050½. The corpuscles presented abnormal shapes, and there was obvious escape of hæmoglobin into the plasma. (See Chart 6.)

Temperature.	Pulse.	Resp.	Urine. Albumen.	Urine. Blood-colouring matter.
Bef. expos. 97·8°	—	—	None.	No guaiacum reaction, and no absorption bands.
2 P.M. .. 96·2	76	14	None.	
2.15 .. .. 97·3	82	18	None.	
2.30 .. .. 98·6	73	17	Trace.

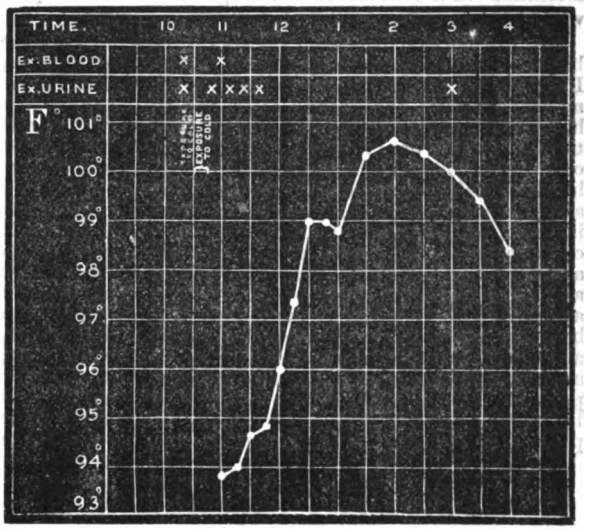
3.30 .. .. 99·2	87	16	Fair trace.	
3.45 .. .. 99·2	82	15	Trace.	
4 .. .. 98·4	82	14	None.	



EXP. 10 (March 18th).—At 4.15 P.M. the blood was re-examined; and, excepting that there appeared to be an increase of 40,000 red corpuscles per cubic millimetre, it was in exactly the same state as at the last examination. At 4.30 P.M. he placed his hands in water which had been reduced by ice to a temperature of 40°, and kept them in it for a quarter of an hour, at the end of which time a series of similar observations to those made earlier in the day was conducted. The results are given in the following table:—

Temperature.	Pulse.	Resp.	Urine. Albumen.	Urine. Blood-colouring matter.
4.45 P.M. .. 98·4°	84	17	None.	None.

6.45 .. .. 98·9	74	16	None.	None.

It will be observed that hæmoglobin appeared in the urine half an hour after the removal of his hands from the water. The urine throughout was clear and transparent, of a port-wine colour, and entirely free from deposit, and, under the microscope, from blood-corpuscles. The blood in every instance was in the form of hæmoglobin, and no traces of acid hæmatin were detected. A specimen of blood examined at 4.45 P.M. presented only 2,950,000 corpuscles per cubic millimetre. The hæmoglobin in the specimen of urine passed at 5.45 P.M. was converted into acid hæmatin by a two hours' sojourn in the incubator at body temperature.

EXP. 11 (April 13th).—The patient had remained well and quite free from hæmaturia since the last experiment. At 10.30 A.M. he had a cold bath containing forty-eight gallons of water at a temperature of 51°, in which he

CHART 7.

remained for ten minutes. The blood examined previously to the bath presented 3,999,000 red corpuscles in a cubic millimetre, while the hæmoglobin power was 53 per cent. That examined fifteen minutes after the bath contained 3,175,000 corpuscles, and presented a hæmaglobin power of 49 per cent. The urine examined before the bath was normal. After the bath the patient had one or two slight rigors, and complained of "pins-and-needles" in his hands, which were white and cold. At 11 A.M. his temperature was 93·8°, and by 12 it had only risen to 96°. By 2 P.M. it had reached 100·6°, after which it gradually fell, until at 4 P.M. it was 98·4°. The urine passed at 10.50 A.M. (ten minutes after taking the bath) contained neither albumen nor blood pigment; that passed at 11.5 presented hæmoglobin; that passed at 11.20 presented hæmoglobin in large quantity; and that passed at 11.35 also presented hæmoglobin. A specimen passed at 3 P.M. contained a small quantity of acid hæmatin. (See Chart 7.)

The patient, who is still in St. Thomas's, has remained perfectly free from the attacks since the last experiment, on the 13th inst. He looks better now than he has looked for a long time, and but for occasional lumbar uneasiness or pain, which he has suffered from more or less during his illness, seems quite well. Before dismissing the case I may mention one or two phenomena connected with it, which I have not hitherto mentioned or have only incidentally alluded to. In the first place, he has (while under observation) always had a sallow hue; but this at the times of the greatest anæmia has amounted to definite, though slight, jaundice, such as one not uncommonly sees in cases of pernicious anæmia. In the second place, when he has been specially anæmic we have been able to observe capillary pulsation in the lips, such as is often observable in other cases of extreme anæmia, and is usual in aortic regurgitation. In the third place, at the commencement of his attacks, even if there has been no shivering, he has almost without exception complained of a sense of uneasiness and swelling in the throat, which has been so great as to prevent him from swallowing. But nothing in the condition of the throat has been detected sufficient to explain it.

(To be concluded.)

ON SUTURE OF THE BLADDER WOUND AFTER SUPRA-PUBIC LITHOTOMY,

AND ON SUPRA-PUBIC CYSTOTOMY WITH PERINEAL DRAINAGE FOR RETENTION FROM STRICTURE, AND RUPTURE OF THE NECK OF THE BLADDER FROM FRACTURED PELVIS.

BY C. J. BOND, F.R.C.S.,
SURGEON TO THE LEICESTER INFIRMARY.

THE following remarks are the result of observation of some cases of supra-pubic cystotomy operated on for various causes during the last two years, in which one or two alterations in the usual method of procedure were adopted with, I think, a certain degree of advantage.

Supra-pubic lithotomy.—Of the six cases operated on, the bladder wound was carefully sutured in four. All of these, I am glad to say, healed by primary union, and there was no leakage from the wound after the first twenty-four hours. Two of these cases were boys under twelve, and two were adults over forty. A few words as to the method of the operation may be useful. The bladder is distended in the usual way with boracic lotion until it rises well above the pubes, and in the adult this may require the injection of from twenty to thirty ounces; latterly in children and in adults I have not distended the rectum at all. The coats of the bladder are then cut down upon and exposed without any dissection, the peritoneal fat and areolar tissue in front of it being drawn upwards from below by the forefinger of the left hand; this is, I think, a point of some importance, as it prevents hæmorrhage, and the bladder can be reached when not so distended or prominent as usual. A fine No. 0 silk suture is then passed by means of the doubly curved needle with eye at the point (Fig. 2), through the muscular coats at the upper

FIG. 1. FIG. 2.

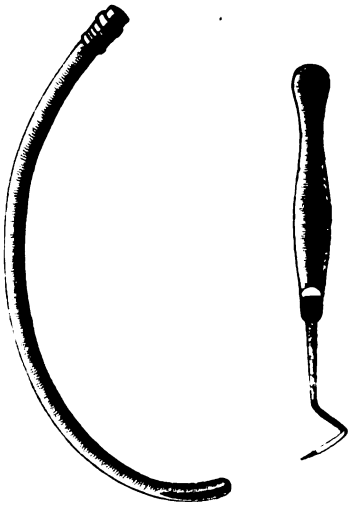

FIG. 1.—Curved staff for passing through urethra from within the bladder.
FIG. 2.—Needle with double curve and eye at point.

end of the wound, and as near the peritoneal reflexion as possible. This marks the upper limit of the incision, and serves to hold up the bladder. It is very important to make the incision as near the top of the bladder as possible, as the ease with which the subsequent sutures are introduced depends on this point. After the incision and extraction of the stone the bladder is thoroughly irrigated with antiseptic lotion, and the sutures are introduced. These are of very fine No. 0 silk, and are passed through the muscular coat on either side of the incision by means of the doubly curved needle mentioned above. They are very close together, and are inserted while the wound is held on the stretch by the upper suture. They thus tend to approximate even more closely as the bladder contracts. Especial care is taken to pass the lower suture below the level of the actual incision. The abdominal incision is then sutured and dressed with dry dressings, a drainage-tube being left at the lower angle. No catheter is left in the bladder.

It is noteworthy that in three out of the four cases some urine escaped between the bladder stitches on the first occasions of passing urine within twelve hours after operation, and this occurred whether a catheter was used or not. In none of the cases was a catheter necessary after the first twenty-four hours, and in the last case, an adult, the urine was drawn off six hours after operation, and none escaped from the wound. In none of the cases did this escape of urine between the stitches delay the union, which appeared to be complete in thirty-six hours, all the urine being then passed naturally.

In stout men the difficulty in suturing the bladder, though considerable, is by no means insurmountable, and the points of greatest importance in order to ensure success appear to be: First, to produce a healthy acid condition of the urine before operation by means of rest in bed and the administration of boracic acid internally in from five- to ten-grain doses thrice daily for some days before operation; the effect of this drug in clearing up the foul alkaline urine and relieving the cystitis caused by calculus is very marked even in from twelve to twenty-four hours after administration. Secondly, care must be taken to avoid bruising, either by handling or by dissection, of the coats of the bladder. Thirdly, the suturing must be done very closely and with very fine silk, care being taken to close both angles of the wound. Fourthly, no catheter should be left in the bladder, and the instrument should be used as little as possible after operation. Finally, the escape of acid normal urine between the stitches during the first twelve hours after operation does not in any way prevent primary union of the wound.

Of the two cases in which no attempt was made to suture the bladder incision, the first was an old man, aged sixty-three, in whom the urine was persistently foul and alkaline, and the patient much debilitated, and I regret I was at that time unaware of the value of boracic acid given internally; he, however, made a good recovery. In the second case one of the calculi was encysted, and this case requires a further description. The patient was a fairly healthy man, aged sixty-one. Three months previously he had been operated on for stone by the lateral method, and had fourteen small stones removed. Recovery was rapid, and he left the hospital on Oct. 30th, 1888. Within a fortnight, however, he began to suffer again from frequent micturition, and was sounded, but with a negative result. On Feb. 8th, 1889, he came to the infirmary with complete retention, and a stone was felt while drawing off the urine; the latter was alkaline and purulent, but soon cleared up under boracic acid given internally. The bladder was opened after distension in the usual way, and a small stone resembling the other fourteen removed. On passing the finger over the base of the bladder a small, hard, spicule or projection was felt behind the prostate, fixed in the mucous membrane, which closely surrounded it. This proved to be the projecting part of an imbedded calculus, which was only removed after considerable difficulty. The base of the bladder and encysted stone were first pushed up and fixed by the finger of an assistant in the rectum, then by means of the finger nail and edge of a scoop the mouth of the sac was enlarged and the calculus turned out of its bed, which when empty admitted the first joint of the forefinger, and was only separated from the rectum by a thin layer of tissue. It was situated about an inch behind the prostate and a little to the right of the middle line. The bleeding was slight, but owing to the prolonged manipulation no attempt was made to suture the bladder wound, but it was drained through the perineum by the following method. The round-lipped vesical opening of the urethra was felt by the forefinger introduced into the bladder, and the sound or staff having the one large special curve (Fig. 1) was passed along the finger and through the urethra until it passed through the membranous portion and bulged in the perineum just below the situation of the bulb. It was now held by an assistant, the legs were raised, and the point of the instrument, which was felt through the skin, was cut down upon, and the urethra opened on the groove which occupied the under surface of the end of the staff, which in this position more or less faced the operator; the sound now projected, and was drawn through, and with it a full-sized indiarubber tube, with two openings on its convex side, attached to the other end of the instrument; this was left in the bladder, and kept it well drained;

Digitized by Google

through it also the bladder could be frequently flushed after compressing the portion of the tube outside the perineum, and again drained by releasing the tube. The tube in this case was withdrawn, so that the upper end lay inside the bladder on the fourth day, and removed entirely on the sixth day. The perineal wound healed three days later, but urine escaped from the upper opening for eight days longer.

This case illustrates a point of considerable interest in reference to the connexion between an encysted calculus and other calculi felt in the bladder. On careful examination each of the fourteen small calculi will be found to be for the most part of the same size and shape, and there is on each a little roughened projection on one surface. It seemed to me at first probable that this was owing to the fact that each of the fourteen calculi had commenced as a deposit on the projecting portion of the encysted one, and had subsequently been broken off and freed by contractions of the bladder wall. On section, however, it was shown that this little roughened process did not extend to the uric acid nucleus, and stopped short at the phosphatic outer coating; hence they arose, probably, as independent renal nuclei, and the roughened projecting spots on each may be probably due to deposit while in contact, and perhaps temporary adhesion to the encysted calculus at these places.

In comparing the after-condition of those patients in whom after supra-pubic lithotomy the wound has been closed and unites by primary union with the condition of those in whom the wound is left open and unites by granulation, I am inclined to think that the granulating process, accompanied as it is by the formation of cicatricial tissue binding the bladder to the abdominal wall, leads occasionally to some inconvenience; for in the first of the two cases in which the wound was allowed to heal by granulation the patient complained for some months after the wound was healed of a painful dragging sensation above the pubes when he emptied his bladder, as though it was anchored at this spot and did not readily slide beneath the peritoneum into the pelvis when emptied. This fact and the great shortening of the period of convalescence when the bladder wound is closed by suture all point to the strong desirability of attempting this in suitable cases; for if unfortunately primary union does not occur, yet even then no harm has been done.

Supra-pubic cystotomy for retention from stricture.—We now pass to the consideration of the second class of cases in which the distended bladder was opened above the pubes, when no instrument could be passed by the natural channel. The first case was that of a man, aged fifty-five, in whom the cause of the retention was stricture of long standing (thirty years), accompanied with perineal fistulæ. As no instrument could be passed, and as it was necessary to drain the bladder, and not merely to draw off the urine by aspiration, I first made a prolonged and careful attempt to open the urethra beyond the stricture, but failed. The distended bladder was then incised above the pubes in the ordinary way; and feeling for the urethral orifice with the forefinger, the curved staff (Fig. 1) mentioned above, with the attached drainage-tube, was readily passed out through the perineal wound, and the bladder thus drained effectually. The relief in this case was very marked. The upper wound closed around the drainage-tube, and all the urine soon flowed by the lower opening. The tube was drawn into the bladder on the tenth day, and the upper opening allowed to close, and the tube eventually withdrawn entirely, a catheter being passed occasionally through the perineal opening. From the beneficial result experienced in this and other cases, I think it probable that in cases of retention from bad stricture, in which the bladder requires free drainage, the supra-pubic incision with perineal counter-opening, in the way above described, will be found to be the easiest and most effectual method of treatment.

Supra-pubic cystotomy for retention from laceration of the neck of the bladder from fracture of the pelvis.—In this case the conditions were somewhat different. A man, aged twenty-four, was crushed by a fall of earth. He was admitted two days later with swelling of the scrotum and lower part of the abdomen. A full-sized silver catheter was passed with some slight difficulty into a cavity, and blood-stained urine was withdrawn, but the impression conveyed to the touch was not that of having entered the bladder. No urine had been passed naturally since the accident; the diagnosis was fracture of the pelvis with rupture of the bladder either of the intra- or extra-peritoneal variety. I first, through a short median incision, opened the peritoneal cavity and ascertained by the finger that there was no intra-peritoneal rupture; the bladder could be felt somewhat distended, and there was no escape or smell of urine. The peritoneum was therefore carefully stitched with catgut, and the incision in the abdominal wall prolonged downwards, and the bladder exposed on its extra-peritoneal aspect. Blood-stained urine now began to well up from a cavity just behind and below the symphysis, and the finger here detected fractured and projecting bone, and the end of the catheter lying not in the bladder, but in the cavity containing urine which surrounded its neck. The bladder was opened, and the curved staff (Fig. 1) with a drainage-tube passed through the urethral orifice and into the perineum, where it was cut down upon and drawn through, and the bladder thus drained. Now, although in this individual case the patient died afterwards from the effects of the extravasation of urine into the areolar tissue of the pelvis, which occurred during the two days that elapsed before his admission and relief by operation, yet the actual result of the operation as shown at the post-mortem examination is, I think, encouraging. It was found that the bladder had been completely separated by the injury at its neck from the urethra, and pushed up into the pelvis, away from the triangular ligament, by the fractured ramus of the ischium; and as distension came on urine escaped into the pelvis. Now the drainage tube had completely drained the ruptured and displaced bladder, and also the cavity around the ruptured neck, and the distended scrotum and perineum had subsided; in fact, there was little or no urine in the pelvis, or about the seat of fracture. Moreover, in this case it would have been almost impossible to have reached the bladder from the perineum, or for the extravasation in the pelvis to have been drained in any other way. The peritoneum was found securely closed, and no trace of peritonitis in the abdominal cavity existed. These cases point, as it seems to me, to the advantages of a combined supra- and infra-pubic exploration and drainage of the bladder for the conditions described above, and may, I hope, lead others to adopt this method of treatment in suitable cases.

Leicester.

CANCER OF THE MALE BREAST, BASED ON THE RECORDS OF ONE HUNDRED CASES; WITH REMARKS.

BY W. ROGER WILLIAMS, F.R.C.S.,
SURGEON TO THE WESTERN GENERAL DISPENSARY, AND SURGICAL REGISTRAR TO THE MIDDLESEX HOSPITAL.

IN most treatises on diseases of the breast this subject is dismissed in a few lines. Considering the large amount of material available, such a state of things is extremely unsatisfactory. That fuller information about cancer of the male breast is desirable, both on its own account and because of the value of such knowledge as a factor in the solution of many problems relating to cancerous disease in general, I have not the slightest doubt. Therefore I have undertaken the present investigation, which is based on the record of 100 cases collected from various sources, and on information otherwise derived. I will now proceed without further remark to lay before the reader the results at which I have arrived, arranged under their various headings.

Relative frequency.—Of 15,481 neoplasms consecutively under treatment at Middlesex, St. Bartholomew's, St. Thomas's, and University College Hospitals during the last sixteen to twenty-one years, 2422 originated in the breast—males 25, females 2397. These were distributed thus:—

Kind of neoplasm.	Males.	Females.	Total.
Cancer	16	1863	1879
Sarcoma	3	92	95
Myxoma	2	2	4
Adenoma	1	372	373
Lipoma	1	1	2
Papilloma	..	3	3
Chondroma	..	1	1
Angioma	1	..	1
Cystoma	1	63	64
Total	25	2397	2422

Whence it follows that 15 per cent. of all neoplasms originate in the breast; and of these only about 1 per cent. originate

Digitized by Google

in the male breast. This is a good illustration of the law that *obsolete structures have but little tendency to take on the neoplastic process.*

Variety.—Cancer of the male breast, as of that of the female, may originate either from the acini, the ducts, or the skin. Thus there were of my 100 cases :—

Acinous, 91—scirrhus, 88 (melanotic, 2), encephaloid, 3.
Tubular (cylinder-celled duct cancer), 6.
Cutaneous squamous-celled epithelioma, 3 (melanotic, 1).

In 26 of these cases a microscopical examination had been made: 17 were fibrous alveolar cancers (melanotic 2), 6 cylinder-celled duct cancers, and 3 squamous-celled cutaneous epitheliomas (melanotic 1). Whence it appears that the male breast is relatively more liable to the tubular variety of cancer, originating in the excretory ducts, than the female; this one might have expected *a priori*, because in the normal condition of the male breast ducts predominate and acini are but imperfectly developed.

Squamous-celled epithelioma of the skin of the nipple, areola, or mammary region is an exceedingly rare affection in both sexes. Among my 2422 cases of mammary neoplasms there is not a single example of it. Billroth has gone so far as to deny its occurrence in the female breast, but Czerny has since described a case—the only one of the kind on record. We see, then, in accordance with the rule for epithelioma of the skin in general, that males are much more liable to this variety of breast cancer than females. Another fact to be noted is the relatively frequent occurrence of melanotic cancer in the male breast (3 per cent.). We may perhaps find an explanation for this if we recall the fact that we here have to do with an obsolete structure which has lost most of its special characters, and is gradually reverting to the primordial cutaneous condition out of which it formerly evolved. With regard to the 3 cases of so-called encephaloid cancer I have little to remark, since in all the histological examination is wanting. I will only mention that of 306 cases of cancer of the female breast under treatment at the Middlesex Hospital during the last seven years there was not a single example of encephaloid cancer; all the supposed cases of this kind on microscopical examination proved to be sarcomas.

Leaving the cutaneous epitheliomas for separate treatment, I will now give an analytical summary of the remaining 91 cases; for I have ascertained, by working out the histories of the tubular and acinous cases separately, that they differ in no essential particular.

Age.—The earliest age at which the disease was first noticed (in 90 cases) was 20 years; the latest 82 years; the mean age 50 years. In the subjoined table the numbers for each quinquennial period are given, calculated on the percentage basis, and for comparison I have appended the corresponding numbers in cancer of the female breast:—

Sex.	Total number of cases.	20 to 25 yrs.	25 to 30 yrs.	30 to 35 yrs.	35 to 40 yrs.	40 to 45 yrs.	45 to 50 yrs.	50 to 55 yrs.	55 to 60 yrs.	60 to 65 yrs.	65 to 70 yrs.	Over 70 yrs.	Mean age.	Earliest age.	Latest age.
Males	90	2	2	9	12	11	17	15	12	7	3	10	50	20	82
Females	500	0·6	4	6	14	16	20	15	10	9	3·2	2·2	48	22	84

It will be seen from this table that the average age at which the disease originates in males is 2 years later than in females. It is further noticeable that a relatively large number of the male cases begin over 70. In most other respects there is remarkable similarity as to the age distribution in the two sexes. Not a single case originated in either sex under the age of 20.

Total duration of life.—In 18 fatal cases the total duration of life, dating from the time when the disease was first noticed, averaged 61 months, which is about 8 months longer than the average duration of the disease in the opposite sex.[1] Of the above cases, 5 had undergone amputation of the breast &c.; in these the duration of life averaged about 124 months; or 20·5, 27, 117, 182, and 273 months each. In the other 13 cases no operation had ever been performed: in these the duration of life averaged 38 months—the shortest period 11 months, the longest 85 months.

Duration of life subsequent to amputation for the primary disease.—This was noted in 6 cases; it averaged nearly 60 months. The exact duration in each case was as follows: 26 days, 1 month, 5, 13, 78, and 260 months. In 25 similar cases of the female breast I found the average period was about 40 months, the longest 259 months.[2]

Interval between first operation and first obvious recurrence. In 14 cases this averaged 9·7 months, the maximum 32·5, the minimum 1·5 months. In females, according to my observations, the average interval is 26 months. In further illustration of this subject I append the following:—

3 months and under in 3 cases.	13·0 months in 1 case.
3 to 4 months in 5 cases.	19·5 ,, 1 ,,
8 months in 1 case.	26·0 ,, 1 ,,
10 ,, 1 ,,	32·5 ,, 1 ,,

Civil state.—Of 12 cases, 7 were married, 2 widowers, and 3 single. Particulars with regard to offspring are given in 3 cases: one was the father of 6 and another of 15 children; the other had no offspring. In 38 cases the occupation had been as follows: butcher, gentleman, and carpenter each in 3 cases; sailor, compositor, merchant, teacher and clerk, each in 2 cases; soldier, brass-finisher, 'bus conductor, piano factory, chimney-sweep, clergyman, blacksmith, locksmith, publican, labourer, waggoner, hospital attendant, plasterer, peasant, bootmaker, carrier, coachman, stone sawyer, and hall porter, each in 1 case.

The side affected.—Right side in 38 cases, or 53 per cent.; left in 33 cases, or 47 per cent. In females the left breast is always the more frequently affected. Of 151 cases, I found: left, 84 (56 per cent.); right, 67 (44 per cent.). In 4 of the above 71 cancers of the male breast, both breasts were affected on admission, but in no instance were both breasts primarily affected. Similarly of 151 cases in females, in 7 both breasts were involved on admission.

Seat of initial lesion.—This was noted in 14 cases: in 8 the disease was central, being situated underneath the nipple; in 3 it was near the nipple; in 1 below the nipple and to its axillary side; in 1 below and to its sternal side; and in 1 above the nipple and to its axillary side.

Character of initial lesion.—In 42 cases this was as follows: small nodule or lump (varying in size from a pea to a hazel-nut) in 30 cases; enlargement and induration of gland in 5; and redness, soreness, or induration of nipple or areola (Paget's disease 1) in 7. In the female breast Gross found that the development of cancer commenced as Paget's disease in 1·31 per cent. of all cases.

Discharge from the nipple.—This was noticed during the course of the disease in 7 out of 91 cases: it was sanious in 4, puriform in 2, and lactiform in 1. According to Gross, females are liable to similar discharges in 15 out of 207 cases.

Previous injury or disease of breast.—Of 30 cases there was a history of previous injury or disease in 16, or 53 per cent., as compared with 43 per cent. in females. The injuries are described as contusions in 10 cases, recurrent pressure at work in 2, and strain in 2. The only previous disease noted were two cases of long-standing eczema of the nipple and areola.

Previous health.—This was stated in 13 cases. It had been good in 11 (with no serious illness since youth in 3) and bad in 2 cases. The following previous diseases are noted as having occurred since childhood: pneumonia and migraine each in 2 cases; tubercular arthritis of knee, hæmorrhoids, eczema, erysipelas of face, herpes zoster, chancre, gonorrhœa, epilepsy, and dyspepsia each in 1 case. With regard to the patients' habits, 3 are said to have been temperate and 3 intemperate. As to syphilis, inquiries were made in 7 cases, but there was evidence of this disease only in 1.

Family history.—Of 29 cases in which inquiries were made, there was history of cancer in 7 families, or in 24 per cent. This is almost exactly the same result as I obtained in females, there being a history of cancer in 33 out of 136

[1] Vide Middlesex Hospital Surgical Report for 1885, p. 87.

[2] Ibid.

Digitized by Google

cases. The relatives thus affected and the seats of the disease may be shown as follows:—

Father's mother (one family) ...	Locality not stated.
Father's sister (one family)	Breast.
Fathers (four families)	Neck. Liver. Breast. Locality not stated.
Mothers (three families)	Tongue. Lip. Locality not stated.
Patient's sisters (two families) ...	Breast. Locality not stated.

Thus of the 7 cases in which the seats of hereditary disease are stated the breast was affected in 3. In 3 cases there was history of cancer in more than a single relative—thus: (1) father died of cancer of neck, and mother died of cancer of tongue; (2) father died of cancer (locality not stated) and 2 of patient's sisters (1 of breast, the other locality not stated); (3) father's mother and patient's mother both died of cancer (locality not stated).

Duration of the disease from the time it was first noticed until the patient came under observation.—In 86 primary cases this averaged 29·5 months; in 119 primary cancers of the female breast the average was 26·5 months, the minimum period 3 months. The following statement further illustrates this subject:—

Under 6 months in	7 cases.	36 to 42 months in	11 cases.
6 to 12 months in	15 ,,	42 to 48 ,,	1 case.
12 to 18 ,,	14 ,,	48 to 54 ,,	10 cases.
18 to 24 ,,	7 ,,	60 to 66 ,,	2 ,,
24 to 30 ,,	12 ,,	78 to 84 ,,	3 ,,

104 months in 4 cases.

In 10 recurrent cases the duration of the disease on admission had averaged 62 months, as compared with 75 months in 39 cases of recurrent cancer of female breast. In 2 cases the duration of the disease had exceeded 102 months—viz., 129 and 130 months respectively.

State on admission.—Of 26 primary cases, 20 were well nourished (obese 4, sallow 1); of these, 9 were ulcerated and 11 non-ulcerated. The other 6 cases were weak and emaciated (sallow 2); of these, 5 were ulcerated and 1 non-ulcerated. In 14 of the above cases retraction of the nipple was noted. In 2 cases the primary disease had assumed the atrophic form, in 2 cases the diffuse discrete form, and in 1 case the *en cuirasse* form; in the others it presented a more or less circumscribed mass. Of 3 recurrent cases, 2 were non-ulcerated (1 well nourished, 1 weak and emaciated); 1 was ulcerated, the patient being weak, emaciated, and sallow.

The axillary glands &c.—Of 68 primary cases, there was obvious enlargement of the axillary glands in 43, or in 63 per cent. In 118 primary cases of the female breast I found the axillary glands affected in 86 or in 73 per cent. In 2 cases the glands near the clavicle were affected as well; both of these were ulcerated. Of the 43 cases in which the axillary glands were affected, 26 were non-ulcerated and 17 ulcerated. Of 25 cases in which there was no obvious affection of the axillary glands, 20 were non-ulcerated and 5 ulcerated. Of 12 recurrent cases, there was obvious enlargement of the axillary glands in 4 (clavicular glands as well in 1 non-ulcerated case); of the latter, 2 were ulcerated and 2 non-ulcerated. The other 8 cases, in which there was no glandular affection, were all non-ulcerated.

(To be concluded.)

BURIALS IN THE METROPOLIS.—A return has been published giving the numbers of bodies at present interred in the principal burial places in the metropolis as follows:—Abney-park, Stoke Newington, 82,570; Brompton Cemetery, 155,064; St. Mary's, Battersea, 24,648; Camberwell Cemetery, 80,790; St. Paul's, Deptford, 50,459; St. James', Highgate, 76,220; All Soul's, Kensal-green, 80,265; St. Mary's Kensal-green, 56,246; Lambeth Cemeterry, 109,010; South Metropolitan Cemetery, 73,750; All Saints', Nunhead, 65,550; Paddington Cemetery, 82,536; City of London and Tower Hamlets Cemetery, Mile-end, 247,000; and Woolwich Cemetery, 27,687. The total numbers of bodies registered as buried in metropolitan cemeteries is 1,276,875.

ON THE TREATMENT OF CHRONIC URÆMIA BY MORPHINE.

BY STEPHEN MACKENZIE, M.D., F.R.C.P.,
PHYSICIAN TO, AND LECTURER ON MEDICINE AT, THE LONDON HOSPITAL, ETC.

(Concluded from page 209.)

IT is not the purport of this paper to discuss at length the pathology of what, for want of a term, we call "uræmia." By this term we understand the various symptoms that arise from the retention in the blood of the various excrementitious substances naturally excreted by the kidneys, whether this arises from disease of these organs or from some impediment to the escape of urine. The subject is one of extreme complexity, which has gone through many phases reflecting the waves in the tide of physiological and pathological advances. It was very fully and ably dealt with by Dr. Carter in his Bradshawe lecture last year.[1] I propose to deal with it only in so far as it enables us to understand the *rôle* played by morphine in its treatment.

It is now generally agreed that (1) uræmia is a poisoning of the nervous system—a toxæmia; (2) the poison is developed within the body of the sufferer—auto-toxæmia. All recent researches go to prove that the poison is not simply urea, though urea is certainly poisonous. The conclusion has long been reached by all workers at the subject—Grainger Stewart, Dickinson, Bartels, and others—that the poison is not one, but several. Bouchard claims to have been able to determine the existence of seven distinct toxic substances combined together in the most variable proportions under different circumstances, of which two were convulsivant, one of the two being the colouring matter or contained in it; one (probably urea) diuretic, one narcotic, one sialogogue, one pupil-contracting, and one temperature-reducing. He traces the toxicity of the urine to the four following sources: 1. Aliments, and more especially their potassium compounds. 2. The absorbed products of intestinal decompositions. 3. Secretions, such as the bile, saliva, &c. 4. Tissue degenerations. He further finds that the toxicity of the urine varies both in kind and degree at different hours of the day and night. Researches such as those conducted by Bouchard, Feltz, and Ritter, and others, whilst they require repeated confirmation, are very suggestive in serving to explain both the varying symptoms of uræmia in the same patient or in different patients in a way not hitherto possible.

Uræmia, then, is a poisoning of the nervous system, and the poisons are formed within the body of the patient. How is it to be treated? There are three principles: (1) To eliminate from the system the poisons already present; (2) to counteract the poisons; (3) to prevent the further formation of poisons. Treatment to be of permanent good must always be directed to the first and last aims. The first we attempt by promoting the action of the skin by hot-air baths, packing, &c., and by the use of diaphoretics, especially jaborandi or pilocarpine; by carrying off waste products and their decompositions from the bowels by means of hydrogogue cathartics; and by increasing the flow of urine by vegetable and saline diuretics. The last aim, the prevention of the formation and the absorption of further poisons, by greatly limiting the nitrogenous diet, as by placing the patient on an exclusively milk diet, and by controlling intestinal decomposition by certain drugs. But whilst we are endeavouring, as should be done in every case, to get rid of the poisons and prevent further formation, our patient may succumb to the effects of those present. Here comes in the second principle of treatment—namely, the attempt to counteract the poisons. Every bane has its antidote. The counteraction of the poisons is not only of service in minimising the effects of the poisons, but is of further help in enabling us to gain time to carry out the other indications already discussed. Thus in uræmic convulsions experience has taught that the damaging and often fatal results are held in check by inhalations of chloroform and by the internal or rectal administration of chloral. Morphine has been used, more especially by American

[1] THE LANCET, vol. ii. 1888, p. 355.

Digitized by Google

physicians, for the same purpose in these cases, and it is claimed with better results.

It will have been noticed that the most prominent symptom in the first case, and a distressing symptom also in the second, was difficulty of breathing—uræmic dyspnœa, or so-called renal asthma. This, in its typical form, is not a very common symptom of uræmia, though I should not, from my own experience, have thought it was so rare as it appears to have been in that of Sir William Roberts.[2] This uræmic dyspnœa merits some consideration. It generally comes on, often suddenly or rapidly, in the evening or early night, is often very intense, lasts for some hours, and gradually passes off in the morning. It returns night after night, and the patient may be quite free from dyspnœa in the daytime. I have known such cases diagnosed as ordinary asthma, the renal origin being unsuspected. I have long been in the habit of teaching that, when such a case is examined at an early stage of the attack—that is, during the first few nights—it is remarkable how little is to be heard, differing altogether in this respect from the noisy cooing rhonchi heard in bronchial asthma. I am interested to notice that Dr. Carter makes the same observation. Dr. Sutton is the only other physician whom I have heard direct attention to this point. Later in the attack, bubbling râles and crepitations are heard, indicating the occurrence of œdema of the lungs. It was for this uræmic dyspnœa especially that the morphine was prescribed. I have for some years been accustomed to treat such cases, in addition to the measures indicated under principles 1 and 2, by means of amyl nitrite, nitro-glycerine, chloral with and without alcohol, ammonia and ether, inhalations of oil of juniper, Himrod's cure, chloroform, &c. One of the worst cases of uræmic dyspnœa I have ever observed I saw recently with Dr. W. J. Mackenzie, of Liverpool-road, Islington. I prescribed small doses of nitro-glycerine, frequently repeated, and, if it failed, morphine. The dyspnœa was greatly relieved, I subsequently learned, by the nitro-glycerine. It will be observed that morphine was not prescribed in the cases I have narrated until several of the remedies above mentioned had been ineffectually tried. The relief afforded by the morphine was extremely prompt, and equally successful in each recurrence of the attack. I think all the facts of uræmic dyspnœa, its periodicity, sudden onset, and relief by antispasmodics, point to a spasmodic neurosis due to poisoning of the nerve centres. Dr. Carter, with, I think, great probability in his favour, suggests that the spasm is of the bloodvessels rather than of the bronchial tubes. This accounts for the absence of auscultatory signs in the early stage, and I think the subsequent pulmonary œdema is another point in favour of Dr. Carter's contention. The high arterial tension, on which Traube and Dr. Broadbent[3] have deservedly laid so much stress in uræmia, due to spasm of the arterioles and capillaries, the great rapidity of the heart's action, the cyanosis and clammy sweat noticed in Case 1, all support this view. Dr. Carter suggests the analogy between uræmic dyspnœa and muscarine poisoning, which Dr. Lauder Brunton has shown produces intense dyspnœa, by causing spasm of the pulmonary and other arteries. He further hints the possibility of neurine and choline—which have been separated from the human body by Brieger—structurally and morphologically allied to muscarine, or some closely similar substance, being proved to be the toxic element, which poisons the nervous system and gives rise to the dyspnœa in Bright's disease when not eliminated from the blood. If this be the case, then, as Dr. Carter writes, we may anticipate the time when a physiological antagonist shall be discovered capable of unlocking the spasm and relieving the distress as promptly as atropine does in muscarine poisoning. I venture to suggest that this is how morphine acts in relieving the dyspnœa of Bright's disease. It counteracts the poison, whatever it may be, that causes the spasm of the pulmonary arterioles (or bronchioles).

Headache and convulsions are very common symptoms of uræmia. The former was present in both my cases. The immediate cause of both headache and convulsions, apart from or in connexion with Bright's disease, has been much discussed. There is a good deal of evidence in favour of arterial spasm being the immediate exciting cause of each. This does not of course explain the pathogeny of headache or epilepsy, because we have to look further back for the cause of the spasm of the arterioles. In uræmia we have this to hand. We know we have a poison or poisons in the blood, and we have evidence of spasm of the bloodvessels, so that we are able to connect the cause with its effect. I think we are justified in referring the relief of the headache as well as the dyspnœa to the influence of morphine in antagonising the poison.

Uræmic convulsions were not present in my cases, but I shall immediately refer to their treatment by morphine. The success of morphine in the treatment of uræmic convulsions I should also refer to counteraction of the poison that excites spasm of the arterioles in the cerebral cortex, which is the anatomical substratum of the motor phenomena. As I have already stated, at the time I used morphine in the narrated cases I had only read brief references to the experience of Dr. Loomis and others in the treatment of uræmic convulsions. I have since consulted the original paper of Dr. Loomis, which appeared in the *New York Medical Record*, 1873, p. 365. Here will be found some very striking cases, illustrating not only the safety, but the advantage of the employment of morphine in the treatment of both uræmic convulsions and of other uræmic symptoms, some of which were present in my own cases. Dr. Loomis, writing on the employment of morphine when "premonitory symptoms of acute uræmia were present, as well as during the active manifestations of uræmic intoxication," says:—"So far as I am able to judge its administration has been uniformly followed by good results. In no instance am I aware that I have caused a fatal narcotism." Loomis certainly has shown the courage of his convictions, for he has given half a grain of morphine in a single dose to a patient in complete coma; and what is more remarkable and important, with relief to the condition. Scanzoni appears to have been the first to use morphine for uræmic convulsions, and Loomis mentions that he first gave morphine at the suggestion of Dr. Metcalf. Loomis and his followers have administered morphine in doses of from half a grain to one whole grain by hypodermic injection. Quite recently Mr. Alfred Grace[4] has reported two cases of puerperal convulsions treated by morphine. In the first he gave a hypodermic injection of one grain at a single dose, and later another injection of nearly a grain. In the second case a single injection of a full grain of morphine was administered. Both cases made a perfect recovery. Purdy[5] advises beginning with one-sixth to one-fourth of a grain, and writes, "The range of utility and safety of morphine in uræmia is strictly confined to the convulsive seizures. Its employment is improper in the state of pure coma or chronic uræmia unassociated with convulsions." The cases chronicled by Dr. Loomis and those I now bring forward directly negative this latter qualification. After the statements I have quoted, I shall hardly be accused of bold or venturesome efforts. My friend and colleague Dr. Ralfe, in the Year-book of Treatment, 1889, mentions that in a patient of his suffering from granular kidney, with dropsy and ascites, the subcutaneous injection of one-sixth of a grain of morphia speedily relieved a persistent and distressing attack of renal dyspnœa which all other means had failed to control, and the relief was continued for some days following, without further recourse to the drug. But Loomis claims for morphine not only the relief of dangerous and distressing symptoms, but more decided benefit still. Writing of the hypodermic injection of morphine in such cases, he says: "The almost uniform effect of morphine so administered is (1) to arrest muscular spasm by counteracting the effects of the uræmic poison on the nerve centres; (2) to establish profuse diaphoresis; (3) to facilitate the action of cathartics and diuretics, more especially the diuretic action of digitalis.

Enough has, I hope, been said to justify the further trial of morphine in uræmia. I am not advocating its employment to the exclusion of other remedies of ascertained utility in the treatment of Bright's disease and the uræmia arising therefrom. The evidence I have adduced shows that in spite of the asserted danger of opium and its alkaloid morphine in patients suffering from renal disease, it may in suitable cases be safely employed, and afford relief in the very distressing conditions we often witness in Bright's disease. I do not recommend its indiscriminate use; and in the light of the asserted susceptibility of patients with disease of the kidneys to the toxic effect of opium, it will be given with eyes open to its danger. It certainly afforded striking relief to the cases I have narrated; and though in these I

Digitized by Google

can only claim a palliative and not a curative influence, they were cases which, from their nature and degree, no other result could be expected. In less advanced cases, where the kidneys are capable of recovery, better results may be hoped for, and, indeed, have been obtained.

Cavendish-square, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

REMARKABLE SUICIDE.

By JOHN GRANT, M.B., C.M. EDIN.

AT 8 A.M. on June 2nd I was called to see F. B——, a blacksmith, aged forty-eight. He was lying on his back in bed, dressed in a cotton shirt and flannel under-shirt, dead. He had come home the preceding evening at 6 P.M. partially intoxicated, having been drinking for two days. Of late he had been addicted to drink. He went to bed at once, but left his room in half an hour, coming downstairs. He was quarrelsome, but on persuasion returned to bed. At 11 P.M. his wife tried to rouse him, but, getting no answer, thought it best to let him alone. At 6 A.M. next morning she again tried, but failed. At 8 A.M. her son broke open the door, and found his father in a sitting posture with his back against it, preventing entrance. He did not go in, but ran for a police officer and medical man. The constable arrived first and forced open the door, finding the deceased as described. Round his neck was a common red cotton handkerchief twisted and tied to the door handle. He immediately cut him down and placed him in bed. On examination I found the body cold and rigid. Post-mortem lividity was well marked on the lower part of the back and legs. The pupils were equal, and moderately dilated. The jaws were firmly clenched and the lips blue, but the face as a whole was little altered, and there was no protrusion of the tongue or eyeballs. Round the front part of the neck immediately below the chin, extending upwards and backwards obliquely over the occiput, was a mark produced by the handkerchief; it was about an inch and a half broad, the skin being quite natural and pale; the texture of the cloth was clearly impressed, but there was no roughening or excoriation; at about an inch on either side of the middle line posteriorly the mark ceased. Turning the man on his face, I noticed the buttocks were flattened and white.

Remarks.—It is perhaps worthy of note that the post-mortem external appearances afforded some indication of the position in which death occurred. The presence of the lividity on the lower part of the back and legs, the flattened pale nates showed that the body had assumed a more or less vertical position, and the minute impress of the cloth on the anterior aspect of the throat pointed to its inclination forwards—in fact, indicated that the man had, so to speak, sat down and hanged himself. The handle of the door was only two feet nine inches from the floor. It is probable the deceased made a loop of his handkerchief, hitched it over the door handle, twisted it to fix it there, but leaving space to admit his head. He then sat down on the floor with his back to the door, put his head through the loop, and bent forward. The forward inclination of the body and the drooping of the head probably induced suffocation by pressure of the glottis against the back of the throat. One has only to try the position for a few seconds to become convinced of the congestion it causes in the head. The entire facts showed considerable method and determination on the part of the deceased.

INSANITY FOLLOWING MUMPS.

By R. PERCY SMITH, M.D., M.R.C.P.

INSANITY is well known to be associated with several of the infectious fevers as a complication or sequela, but I am not aware that cases following mumps have ever been recorded. Mumps is not mentioned in the ordinary text-books on insanity under the heading of "Post-febrile Insanity," and therefore the following cases have appeared to me to be worth recording.

CASE 1.—G. R. R. T——, a clerk, aged nineteen, was admitted to Bethlem Hospital on June 19th, 1888. He had enjoyed good health previously to this illness and had never suffered from insanity before, and there was no neurotic inheritance. A fortnight before admission he had suffered from mumps, there being other cases in the family and in the same village. His attack was associated with diarrhœa so severe as to be called "English cholera" by the doctor attending him. The patient was said to have been extremely exhausted and almost pulseless afterwards, and was described by his friends to have been "nearly gone." On recovering from this about five days before admission he became excited, sleepless, and rambling, and passed into a condition of acute mania, in which state he was admitted to hospital. There was no special feature about his insanity while in the hospital; he rather rapidly improved, and was discharged recovered in October last.

CASE 2.—This case occurred in a young medical man who had an attack of mumps complicated with severe orchitis, for which he was admitted to a general hospital, and as a result of which he became depressed and suspicious, thought he was guilty of imaginary crimes for which he dreaded punishment, and was suicidally inclined. He had a short attack of melancholia, which passed off with improvement in his physical health, and eventually he recovered perfectly without the necessity of being sent to an asylum.

It is worthy of note that in both cases there was a severe complication associated with the mumps, so that there was considerable physical exhaustion, this seeming to have more to do with the attack of insanity than and severe febrile process or metastasis.

NODULAR PERIOSTITIS IN CHILDREN'S RHEUMATISM AND HEART DISEASE.

By ANGEL MONEY, M.D., F.R.C.P.

OF the occurrence of subcutaneous nodules we have hay records enough and to spare. It is not so generally known that nodules are rheumatic manifestations in other tissues. Nodular pericarditis, pericarditis with fibrous nodules, nodular pleurisy, and nodular periostitis are, however, undoubted facts. I have notes of a few cases in which subcutaneous nodules were associated with nodules growing from the bone—exostoses—resembling subcutaneous nodules in every respect except that they are firmly fixed to the bone and cannot be dislodged. One case, a boy aged ten, died, and then I was able to prove post mortem that his olecranon had nodular exostoses growing therefrom. He had many nodules in the valves of the heart, chiefly the mitral valve. Rheumatism is a frequent producer of fibrous nodules, limited localised lumps of connective tissue; a nodular sclerosis, different from the nodules of tuberculosis and from the limited fibroid formations of syphilis, but nodules or limited fibrous formations all the same.

Harley-street, W.

CASE OF SUPRA-PUBIC OPERATION OF OPENING THE BLADDER FOR STONE.

By CECIL A. CORKE, F.F.P.S., L.R.C.P., L.S.A.

W. B——, aged sixty-eight, consulted me about four years ago, when he suffered from chronic bronchitis, pain on micturition, and was passing gravel. About twelve months ago he passed some bloody urine, but this symptom has only appeared twice since. I sounded him for the first time in June, and discovered the presence of a stone; but from the symptoms then and in subsequent soundings I concluded that the stone was encysted, and from its position not easy to reach by the ordinary operation of lithotomy, so determined upon the supra-pubic operation.

On Wednesday, July 3rd, chloroform being administered by my coadjutor, Dr. Freeman, R.N., and in the presence of Dr. Sankey of Boreatton and Dr. Sandford of Baschurch, who kindly assisted me, I performed the operation, having first distended the rectum with an indiarubber ball of 10 oz. capacity. I injected ten to twelve ounces of boracic solution into the bladder, carefully dissecting and scratching my way

Digitized by Google

through the tissues. The knife was only used three times. I had no difficulty in reaching the bladder and in extracting the stone, which was, as I had supposed, encysted, and not to be easily discovered; in fact, I at first thought there was no stone, as only a very small surface could be felt, and requiring some little manipulation to free it from its cyst walls. A drainage-tube was passed from the external wound through the urethra, and left *in situ* about five days. The patient has made an uninterrupted recovery, and is now (July 26th) passing all his urine by the urethra, and the wound is nearly healed. The operation was attended by very little hæmorrhage, all veins being held aside, and was much easier to perform than the perineal operation. The stone is about an inch long, half an inch broad, and weighs one drachm five grains.

I place this case upon record as the high operation is only recommended for large calculi; but in all cases of encysted calculi I strongly advise it, and believe it the best resource.

Baschurch.

LARGE BURNS.

By T. SOMERVILLE SMITH, M.D.

ON February 25th C. W——, aged three years and six months, being left alone in the kitchen, played with the fire, burning himself in a dreadful manner. I saw him half an hour after the accident, and found him in a state of collapse, suffering from shock. The extent of the burns, subsequently ascertained, was as follows:—

All over the abdomen, width five inches, length seven; down the left thigh, width three inches, length four; on the back, nine inches long and four wide; round each arm, three inches long and four wide; round the neck, three inches long and three wide. The true skin was burnt through over the whole of the abdomen and a portion of the back. Linen rags steeped in linseed oil and lime water were applied to the burnt surfaces. Purgatives, at first administered, were discontinued, as peritonitis set in, accompanied for nearly a whole day with suppression of urine. The child lay on its back with its legs drawn up, the bowels not being relieved for eight days. There was delirium at night for the first five or six days. The treatment was as follows: Brandy during collapse, with bark and ammonia; bromide of potash for rest at night. Linseed oil and lime water were continued for about a week, at the end of which linseed poultices, with plenty of linseed oil in them, were applied to the abdomen and part of the back to remove the eschars. When the wounds were perfectly clean the whole of the raw surfaces were smeared with an ointment composed of lard, zinc, and glycerine, under which they slowly but surely healed. The child's strength was kept up by tonics. There is a very slight contraction in the left groin, where the thigh and abdomen wounds meet; in all other respects the child is now convalescent.

ST. THOMAS'S HOSPITAL.

CASES OF ORBITAL CELLULITIS AND ORBITAL ABSCESS; REMARKS.

(Under the care of Mr. J. B. LAWFORD, Assistant Ophthalmic Surgeon.)

THESE cases, which are examples of inflammation of the cellular tissue of the orbit, some of which terminated in abscess, illustrate the difficulty often met with in tracing a disease to a definite cause, as well as the successful treatment of a serious condition. In no case was any history of injury obtained, and in only one was disease of the bony wall of the orbit found, making it probable that the suppuration in the orbit was secondary to a localised periostitis. There had been no recent attack of fever or erysipelas, but in Case 4 renal disease was present, the patients were apparently free from evidence of visceral disease. Mr. Lawson[1] speaks of an acute inflammatory exudation into the orbit of a syphilitic nature presenting the characters of a cancerous growth, and considers that some of the firm orbital tumours which had gradually subsided under treatment may have been of this nature. To show the remarkable resemblance, he cites a case in which he was himself misled by this close resemblance to malignant disease. When unable to account satisfactorily for the onset of an inflammation, it is not infrequent to find it ascribed to a chill, and this observation applies equally to orbital cellulitis as to inflammations in other parts of the body. Day[2] described a case of acute exophthalmos. After exposure to cold rain the eye protruded nearly three-quarters of an inch, the pupil being dilated. The protrusion of the eye subsided only after two months, without suppuration in the orbit, and vision continued unimpaired. The fundus was not examined. He ascribed the condition to congestion of the vessels, and perhaps infiltration of serum or blood in the post-orbital tissues. There was apparently nothing to cause the disease excepting the exposure to cold. The subjects of orbital cellulitis and abscess are so frequently depressed and feeble that it is quite possible sudden changes of temperature may lead to a localised venous thrombosis, with a secondary inflammation of the tissues around. The disease may be part of a pyæmic infection of the system, and is occasionally found accompanying the puerperal state. It may be secondary to abscess of the lacrymal gland. The disease may prove fatal by extension of the inflammation backwards to the cerebral membranes, but this is not a frequent sequence. Much more commonly the result of the disease is shown in more or less complete loss of vision in the eye of the affected side, by stretching of, or pressure on, the optic nerve; ulceration of the cornea may also occur from damage to the ciliary nerves behind the globe.[3] As regards prognosis, much will depend upon the period in the course of the disease at which treatment is commenced and the way in which it is carried out, as well as upon the causation of the disease.

CASE 1. (From notes by Mr. Hinnell.)—Charles D——, aged thirteen, a schoolboy, was admitted on Aug. 25th, 1886. The illness began on the 15th, when the boy awoke at night with severe pain in and about the right eye. The lids were then noticed to be swollen. The pain has continued since, and there has been frequent vomiting. There is no history of injury, or of recent illness. Family history unimportant.

On admission, there was marked proptosis of the right eye, the globe being protruded to the outer side of the middle line; almost fixed, but a little outward movement retained. There was slight bluish discolouration of the lids, with very little swelling. The cornea were clear, the pupil equalled the left in size and reaction. V = J.1. Under ophthalmoscopic examination the retinal veins were engorged; the margins of the disc hazy. On palpation there was a sense of resistance beneath the upper orbital margin, with doubtful deep fluctuation. There were no enlarged glands. The child was in pain, looked ill and thin, and was said to have lost flesh rapidly. The tongue was furred. Temperature 97·8°; pulse 66; urine 1032, acid, no albumen or sugar.

Aug. 27th.—The condition of the eye has scarcely altered, but there is more pain. No sickness since admission. The temperature has slowly risen, and remains about 100°. There is now a solid resistance to be felt at the lower and inner part of the orbit. Ether having been administered, an incision was made close to the lower orbital margin towards the nasal side. At a depth of an inch to an inch and a quarter thick fetid pus was discovered, and two to three drachms let out; a small area of rough bone was felt. A drainage-tube was inserted, and an iodoform dressing applied. Pus continued to drain away in small quantities for the next two days. The boy was much more comfortable. The temperature continued above normal.

30th.—More proptosis; discharge of pus continues.

Sept. 3rd.—Considerable chemosis of conjunctiva; eyeball greatly protruded. Ether again administered, and the

[1] Diseases and Injuries of the Eye. [2] Medical News, April, 1888. [3] Nettleship.

Digitized by Google

incision in the lower lid enlarged outwards. No further collection of pus discovered. Steady decrease in the protrusion of the eye ensued; pus continued to escape in small quanti ies. The pain soon ceased, the temperature became normal, and the boy improved in every way.

16th.—Slight recovery of voluntary movement of the eyeball upwards, inwards, and outwards.

21st.—L. V. = J. 1 (slowly). No ophthalmoscopic changes.

28th.—Movements of right eye rapidly increasing in extent. Still considerable proptosis.

29th.—Patient discharged. He was not seen again.

CASE 2. (From notes by Mr. Hinnell.)—William F——, aged two years, was admitted on Nov. 15th, 1886. The history given by the mother was that the child's left eye had been inflamed for a week, and that two days previously the lids had become swollen. The child had refused food, and was feverish and vomited. There was no evidence of injury.

On admission the left eyeball was considerably displaced forwards and slightly downwards. The lids were swollen, tense, and dusky. There was puffiness over the bridge of the nose, and in the left temporal region. Chemosed conjunctiva protruding between the lids at the inner canthus; cornea clear; left pre-auricular gland enlarged. There was swelling of the tonsils and uvula; no suppuration in the former; no membrane seen. Temperature 101·6°.

Nov. 16th.—Ether having been administered, an incision was made through the upper lid below the outer part of the upper orbital margin. Pus was found deep in the orbit. No exposed bone detected. A drainage-tube was inserted and a small poultice applied.

17th.—The swelling is rather less tense. Scanty discharge from the tube. No vomiting. Takes milk well. Morning temperature 100·6°. Warm-water dressing ordered.

23rd.—The swelling is considerably less, and the lids are now quite soft, excepting over a small area around the tube. There is still scanty purulent discharge. The child is much better. Temperature generally normal, occasionally rising to 99° and 100°.

28th.—Drainage-tube removed. Still much displacement of eyeball, but swelling of lids is nearly gone. Chemosis of conjunctiva persists.

Dec. 12th.—The child was discharged from the ward to-day. Steady improvement has taken place since last note. The patient was not seen again.

CASE 3.—Dorothy M——, aged seven months, was sent to Mr. Lawford at the hospital by Dr. M. Read, on Sept. 26th, 1887. One week previously the child had had a fit; beyond this there was no history bearing on the case. So far as was known the child had received no injury. No evident disease of nose or mouth. The left eyelids, especially the upper, were swollen and tense; indistinct deep fluctuation could be felt; eyeball considerably protruded and movements limited; cornea clear; pupil much larger than that of the right eye, remaining so under chloroform. An incision was made through the upper lid in its outer half, and a probe passed deeply into the orbit, but no pus or diseased bone was found. Warm lead lotion dressings were applied. The incision rapidly healed. Two days later the lids were less swollen and tense, but the proptosis was no less, and there was noticeable downward displacement of the eyeball. The left pupil was still larger than the right. The child seemed well, ate and slept well, and suffered apparently very little pain. On Oct. 3rd the swelling of the lids and proptosis had increased; the child appeared to have very little discomfort. The next day Dr. Read made an incision through the upper lid, and let out about half a drachm of pus. On Oct. 5th, when Mr. Lawford saw the child, this incision had closed. On reopening it a small quantity of dark thin pus escaped. No bare bone could be felt with the probe. The displacement and loss of movement of the eyeball was the same as two days previously. Ophthalmoscopic examination revealed nothing abnormal. Mr. Lawford did not see the child again till Oct. 19th. There was then slight displacement of the eye downwards, but it moved freely in all directions; there was still some thickening beneath the upper orbital rim, and the lid could only be raised half way. The optic disc and vessels were normal. On Nov. 2nd there was very slight downward displacement. Some thickening could be felt about the scar of incision. The child then appeared perfectly well. In April, 1889, Dr. Read wrote that the child had had no recurrence, and had been in good health since the above attack. The left eye and eyelids looked quite normal.

CASE 4. (From notes by Mr. Laws.)—James S——, aged twenty-one, a railway porter, was admitted on March 13th, 1889. On March 8th he had throbbing pain in the right eye, and noticed that it was bloodshot, and soon became swollen. Pain continued till the 11th, then decreased in severity, but the swelling became more noticeable. There was no history of injury; no bad teeth; no discharge from the nostrils. Three weeks previously he had a sore-throat, but it had left no trace in the fauces. He has not had syphilis or gonorrhœa, nor any of the specific fevers. He stated that three years ago his right eye was similarly affected, but recovered in a fortnight.

On admisson, there was considerable swelling of the right eyelid, with marked proptosis; the ocular movements were almost abolished; conjunctiva protruded between the lids; the cornea was clear, pupil dilated (probably by atropine used before admission); media clear; optic disc slightly blurred at the inner edge, and the veins tortuous; vision unaffected. Very little pain or tenderness. There was a doubtful sense of fluctuation above the eyeball. The temperature was normal; pulse 80. Heart sounds clear, but apex beat displaced upwards and to the left. Tongue furred. Urine 1035, acid; high coloured; good trace of albumen; no sugar; no casts; large quantity of crystalline phosphates. The patient was kept in bed and given a purgative of the citrate of potash mixture. Warm lead-lotion dressings were applied to the swollen lids. There was no appreciable change during the next two days. The urine became slightly alkaline; albumen still present. There was no urethritis or cystitis. The temperature was normal.

March 16th.—This morning slight serous chemosis of the *left* conjunctiva, and slight tenderness to pressure on the eyeball. No limitation of movement. Condition of right eye about the same. Proptosis decreasing.

20th.—Proptosis of right eye no less, but there is slight return of movements of the eyeball. Pupil active. Cornea clear. Chemosis of left eye almost disappeared. Urine: alkaline, deposit of amorphous phosphates, no albumen to-day, but a few granular casts.

24th.—Right eye improved in every way. Less proptosis, more movement. Left eyelids slightly swollen. Conjunctiva chemosed.

25th.—Left eye: increased swelling and some evident proptosis; movements of eyeball limited, especially upwards and outwards, but there is no pain. No ophthalmoscopic changes in either eye. On the afternoon of this day the patient's temperature rose to 100·8°, and he complained of pain in the left orbit; nausea, but had no shivering.

26th.—Better. Temperature normal. Pain much less. Left eye now more prominent than right. From this date steady improvement took place. Both eyeballs resumed their normal position and regained perfect movement, and sight in each eye = $\frac{6}{6}$. No ophthalmoscopic changes were visible. Albumen was not found again in the urine. The patient left the hospital on April 15th.

June 25th.—He has been quite well since his discharge.

Remarks by Mr. LAWFORD.—Perhaps the most noticeable feature of these cases is the apparent absence of adequate cause for the cellulitis. In not one was there a history of local injury, and in none could I obtain evidence of disease of neighbouring parts from which inflammation might have extended to the orbital tissues. Case 4 is in many respects the most interesting. Here, in an apparently healthy man, cellulitis of the right orbit appeared without ascertainable cause, and extension to the left orbit took place, though the inflammation was less severe in the second orbit. The occurrence in this patient of albuminuria was remarkable and unexpected, and its disappearance concomitantly with the improvement in the local and general symptoms lends support to the hypothesis that it was in some way connected with the inflammatory processes. It is to be noted also that in this patient there was a history of a somewhat similar attack of orbital inflammation previously. The recovery of all four cases without any extension of the inflammation beyond the orbits, and without, so far as can be judged, permanent damage to the optic nerves is matter for congratulation.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA-PARK.

TUBERCULAR ABSCESS OF LIVER; MILIARY TUBERCLES IN LUNGS; NECROPSY.

(Under the care of Dr. THOROWGOOD.)

THIS case is chiefly interesting from the comparative rarity of tubercle of the liver, some of the abscesses from which attained to unusual size in this patient. The German pathologists describe tubercle as not unfrequent in the liver in the general tuberculosis of children, and specimens illustrating the condition have been shown at the Pathological Society.[1] Tubercle of the liver as a primary deposit is almost unknown. "Miliary tubercles are most frequently met with, and are often present in considerable numbers. Occasionally tubercles of the average size of a pea or a bean are observed. They always present a central cavity full of broken-down tissue and biliary colouring matter, with a capsule of yellowish or greyish tubercular growth."[2]

Francis S——, a labourer, aged twenty-one years, was admitted to hospital on Dec. 27th, 1888. The family history was good. He dates his present illness from a cold, caught ten weeks since. Lately he has become short breathed, has night sweats, and is losing flesh. In general appearance he is fair-haired, not emaciated. Appetite good; tongue rather coated; bowels not open; mucous expectoration with cough. Temperature 101°; pulse 100 (feeble); respiration 20. Urine acid, sp. gr. 1020; no albumen; no sugar.

Physical signs. — Chest fairly well covered. Heart's impulse feeble in the fourth and fifth interspaces in the nipple line. A short systolic murmur is heard over the apex. The hepatic dulness commences slightly above the fifth rib. The liver extends downwards about three inches below the costal margin, it feels fairly smooth, and is very tender. The rectus muscle is not markedly tense. Under the right clavicle much crepitant râles with sibilus can be heard, and under the left clavicle the breathing is fair, a few crepitations being audible. Below the right scapula resonance is impaired, breath sounds are very feeble, and faint friction sounds are audible. The spleen seems slightly enlarged.

The temperature during his stay in the hospital was irregular and wide in its range; usually from 101° to 102°, sometimes 103° to 104°. He had no rigors, and was very dull and apathetic in manner. The skin was sallow, but the conjunctivæ were not yellow, and the urine was free from bile. There had been slight œdema of the feet before admission, but never any ascites. He never had coughed or vomited blood. The question was as to the nature of the hepatic enlargement. The persistent febrile condition and the tenderness over the liver, with smoothness of surface, made Dr. Thorowgood suspect abscess, though there had been no rigors, and the patient had never been in a tropical climate. The absence of marked jaundice, blood-vomiting, ascites, and the very slight enlargement of the spleen were against cirrhosis. The evident disease in the right lung pointed to tubercular mischief, and possibly fatty liver. No remedies had any beneficial effect, though five-grain doses of quinine seemed to reduce the temperature from 103° to 101°. On Feb. 27th, 1889, he died, and from the ample record of the necropsy by Dr. Wetherhed, pathologist to the hospital, the following summary is made.

Necropsy, held on Feb. 28th.—The liver weighed 58 oz., was somewhat enlarged, colour pale, congested in patches, substance firm. The upper surface was adherent to the diaphragm, and the lower surface to the duodenum and parts around. Capsule much thickened. The liver was studded throughout with small nodules, varying in size from a pin's head to a large pea. The larger ones were breaking down in the centre, and stained a light green. Some of the cavities thus formed were as large as a chestnut. The contents examined microscopically showed caseous débris and crystals of fatty acids, but no tubercle bacilli could be found. Sections of the nodules showed typical tubercular structure, and in some bacilli were found. There was also a considerable amount of cirrhosis. The glands near the liver were enlarged, and many were breaking down in the centre. The bile-ducts were patent, and no communication could be found between them and the tubercular abscess. There was well-marked peritonitis on the right side, where a small hæmorrhage had taken place. No sign of tubercle in the intestines. Both lungs were full of grey miliary tubercles, and there were no old lesions at the apices.

Remarks by Dr. THOROWGOOD.—The case is of interest as one of tuberculosis of the liver. The disease does not appear common, for Frerichs states that only twice in necropsies of 120 phthisical patients did Louis observe tuberculosis of the liver. In children it is a more common affection than with adults. Dr. Murchison[3] has recorded a case where the liver was enlarged to 77 oz. from miliary tubercles scattered through the glandular tissue; the surface generally was smooth. Cirrhosis, or interstitial hepatitis, is known to be a complication of tuberculosis, but according to Frerichs[4] there is no symptom during life indicative of tuberculosis of the liver. A section of the liver in this case was shown by Dr. Wetherhed as a card specimen in May last at the Pathological Society.

Reviews and Notices of Books.

The Treatment of Epilepsy. By WILLIAM ALEXANDER, M.D., F.R.C.S. Edinburgh and London: Young J. Pentland. 1889.

SOME years ago the author of this work, influenced by the vascular theory of epilepsy, proposed and practised ligation of the vertebral artery as a means of cure of this most incurable of diseases. He has abandoned this treatment, of which the results were not so satisfactory as he had anticipated. He now comes forward with another, and even more formidable, surgical procedure which in his hands seems to bear greater promise. Nor has he hastily arrived at this conclusion, since some of his operations were performed as long as six years ago—a sufficiently long lapse of time to note the good effect, if any, of the operation. This consists in the removal of the superior cervical ganglion with the theoretical object of altering the nutrition of the brain through its vascular supply, and is applicable therefore to whatever view of the nature of epilepsy may be accepted, whether, that is, the primary seat of the disturbance be considered in the medulla (Van der Kolk) or in the cerebral cortex (H. Jackson). Dr. Alexander frankly admits that the procedure is based upon theoretical reasonings; and for some time he naturally hesitated to perform an operation which, according to experimental physiology, should lead to very marked disturbance in circulation and nutrition. However, he set to work to practise its details on the cadaver. His first case—one of facial tic and spasm, which he found to be relieved by pressure on the carotid—proved to be successful, and unattended by deformity or inconvenience beyond slight drooping of the eyelid and contraction of the pupil on the side of the operation. The general description of the operation is best given in the author's own words (pp. 22 and 23):—

"The patient should be anæsthetised with chloroform instead of ether, to avoid congestion of the veins of the neck. The head is placed on one side, and the part to be operated on exposed to a good light. An incision is then made three inches in length, from half an inch in front of the mastoid process, just below the ear, straight down the middle of the sterno-mastoid muscle, until we are stopped by the fear of wounding the external jugular vein. The fibres of the muscle are separated until the sheath and fascia beneath are reached. The sheath is cut through, and the inner side of the wound is drawn well inwards and lifted up. The fascia now seen at the bottom of the wound is also cut through, care being taken not to wound the internal jugular vein. This vein is pulled well inwards with a retractor, when the internal carotid artery will come into view, and the superior cervical ganglion will be

Digitized by Google

seen lying behind it. The ganglion will be easily recognised by its greyish colour and its large size, which rapidly diminishes into a thin cord as we follow it downwards. This cord should be cut below, the lower end of the upper fragment seized by the forceps, and the ganglion freed from its connexion as high up as possible, by snipping with fine blunt-pointed scissors that cut well out to the end. When the ganglion is freed as far as possible, its upper connexion may be most safely and readily severed by traction. Some carbolic lotion is now used to wash out the wound, the inner side of the incision, which has been retracted, is allowed to fall outwards in apposition with the opposite side, after a drainage-tube has been introduced, and the wound dressed with gauze, sublimate wool, or any other antiseptic dressing."

It is needless to remark how much care is required by the operator to avoid injuring the important vessels and nerves which he will encounter in the course of his dissection. Dr. Alexander does not minimise these dangers, and gives many practical directions for their avoidance. He gives details of twenty-four cases of epilepsy thus treated, and after an interval of from four to six years reports of them that six were cured, that ten were improved (especially in their mental condition), and five unimproved. None were made perceptibly worse by the operation; but two died shortly after its performance (not, however, from its direct effects), whilst of one case no further information was obtained. He claims, therefore, that a percentage of recoveries amounting to 25 is an advance on the ordinarily admitted "cures" of epilepsy (7 per cent.) by medical treatment, whilst he avers that they were actually the cases most unfavourable for the latter treatment which recovered under his plan.

Extirpation of the cervical sympathetic ganglia in the human subject might be expected to prove of great physiological importance, since, as is well known, so many striking effects have been observed to follow this operation in the case of animals. It is, however, remarkable how slight were the phenomena observed in Dr. Alexander's cases, and how few of those noted by the experimental physiologist were present. As regards ocular phenomena, a contracted pupil and drooping eyelid were noticeable (but to a very slight extent, as the numerous photographs inserted in the volume show) only when one ganglion was excised. When both ganglia were removed the eyes seemed almost normal, and in neither case was the contractility of the pupil affected; no lacrymation, no evidence of impaired nutrition of the eyeball in any part resulted; whilst as to graver effects, no glycosuria and no cardiac phenomena were ever observed. Nor even was there any notable flushing of the face or rise in temperature, and yet it is remarked that in the cases where opportunity was given by a post-mortem examination an increased vascularity of the pia mater on the side of the operation was apparent. Physiologically, then, this operation has not added much to our knowledge of the function of the cervical sympathetic, except in the way of diminishing its importance in the human subject; whilst from the point of view of the surgeon it is satisfactory that so slight disturbance is occasioned by what *primâ facie* would be considered a very serious interference with the normal mechanism.

Dr. Alexander adds chapters upon Trephining for Epilepsy, and on the medicinal and dietetic treatment of the disease. He points out how detrimental to the general health is the continued and excessive use of bromides, and how few other remedies have any control over epilepsy. "Routine," he says, "is the curse of this disease, and routine generally means bromide." His new method of treatment is certainly calculated to startle us out of such routine. He has found that percussion of the spine (with a mallet over a rubber pad) from the lumbar to the cervical region will afford temporary relief in arresting the fits, and that this procedure may be employed together with galvanism, but that it has no curative power. An interesting chapter upon the General Management of Epileptics contains a description of the home at Maghull. Lastly, there is a chapter on Morbid Anatomy, consisting of details of many cases of tumour, and many of true epilepsy, but in only two, it is remarked, could "brain surgery" have had any reasonable chance of success.

OUR LIBRARY TABLE.

Lectures on the Errors of Refraction and their Correction with Glasses. Delivered at the New York Post-graduate School by FRANCIS VALK, M.D., Ophthalmologist to the New York Dispensary. Pp. 241. New York and London: G. P. Putnam's Sons. 1889.—These lectures are written in an easy and intelligible manner, and contain all, or more than all, the well-educated student need know, unless he is intending to make ophthalmology his special branch of practice. The author remarks very justly that, whilst many things may be learnt from writers, to obtain perfection in the correct detection of the errors of refraction the eye and hand must become accustomed to do their work, just as the skill of the artisan is shown by his manual dexterity in the work that he performs. He adds dryly that he has known some of our best ophthalmologists to differ very essentially on the degree of refraction when they estimate it with the ophthalmoscope. He commences with a description of the orbit, which is correct enough except that the cart is put before the horse in regard to the floor, which is said to be "formed partly by the bones from the inner wall, except in front by a portion of the malar bone, and near the apex by a part of the palatal and superior maxillary bone." The last-named bone should have been named first as constituting the major part of the floor, then the malar and palate bones, and last, as least important, the slight participation of the inner wall. The optic nerve is described as having only one nerve-sheath, a continuation of the pia mater. Why is the dural sheath omitted? The principal properties of lenses are then given, and the following chapters are devoted to Emmetropia, Hypermetropia, and Myopia, and to Ophthalmoscopy. The accounts of these states are of course accurately given, in some cases in a rather colloquial style, but in a way that will render the book useful to all ophthalmological students.

Archiv für Pathologische Anatomie und Physiologie und für Klinische Medicin. Herausgegeben von RUDOLF VIRCHOW. Band cxvi., Heft. 1 and 2. Berlin: G. Reimer. 1889.—The contents of these two parts of "Virchow's Archiv" consist of the following papers:—1. Elasticity of Arteries (healthy and diseased), by Professor Thoma and N. Kaefer (stud. med.). 2. Blood-plates (Blutscheibchen) are Constant Elements of Normal Mammalian Blood, by Dr. C. Laker. 3. Experimental Researches on the state of Intestinal Movements in Lowered Temperature of the Body, by Dr. C. Ludovitz. 4. On Hyaline Changes of the Skin produced by Freezing, by Dr. H. Kriege. 5. On Xanthoma Multiplex, Planum, Tuberosum, Molluscifórme: I. Clinical, by Dr. G. Lehren; II. Anatomical, by Dr. K. Krauss. 6. On Tuberculosis in Vertebrates, by W. K. Sibley. 7. On the Theory of Suppuration, by Dr. P. Grawitz. 8. The Origin of Stenosis of the Air-passages in Tracheotomised Children, by Dr. W. Fleiner. 9. On Nerve Lesion and Loss of Hair with respect to Alopecia Areata, by Dr. G. Behrend. 10. A Historical Sketch of Early Medicine in Rome, by Dr. Saalfeld. 11. Spontaneous Pulmonary Hernia in Adults, by Dr. Strubing. 12. The Action of Astringents, by Dr. Heinz. 13. Relation of Motor Ganglion Cells of the Spinal Cord to the Peripheral Nerves, by Dr. von Sass. 14. On Defective Skulls, by J. Fridolin. 15. Bacteriological Reports on Green Sputum, by A. Frick. 16 On Mycosis Fungoides, by W. Dönitz and O. Lassar. 17. Fibrous Tubercle caused by Ova of Parasites, by Dr. Miura. 18. Notes on the Pathology of

Digitized by Google

the Blood, by Professor Neumann, and a few minor contributions.

Medical Bookkeeping.—We have received for review a prospectus of Mr. P. B. Ferdinand's system of "medical bookkeeping," which describes an attempt to combine an account book and a case book in one set of documents. Strictly speaking, Mr. Ferdinand's invention is not a system of bookkeeping in the business sense, but a particular form of that very useful object, a nest of "pigeon holes" for the orderly preservation of papers. It is designed to receive a number of dockets, in which the memoranda for case book and account book may be noted down and preserved for easy reference. The dockets, being sorted out into distinct compartments arranged in alphabetical order, can be easily found when wanted and carried on his rounds by the medical practitioner in his pocket-book, a suitable form of book being supplied with the apparatus. Thus the medical man has the great advantage of having so much of his case-book as he wants to refer to always at hand, and the want which a busy man always feels of facilities for refreshing his memory as to the history and details of a case is very successfully supplied. The system, the apparatus connected with which may be obtained of the firm of Thompson, Walters & Co., Curtain-road, E.C., seems to be capable of being worked without very much trouble, and we cannot doubt that it will prove to be of great utility.

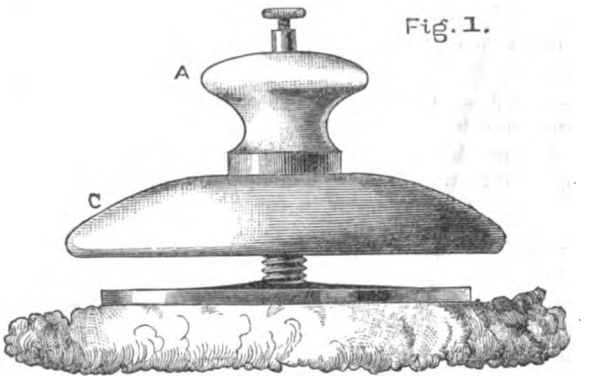
Dictionary of National Biography. Vol. XIX., Finch—Forman. Edited by LESLIE STEPHEN. London: Smith, Elder, and Co.—The nineteenth volume of this important work contains 474 biographical sketches, commencing with Anne Finch, Countess of Winchilsea (d. 1720), poetess, and ending with Simon Forman (1552–1611), astrologer and quack doctor. The College of Physicians summoned him in May, 1593, for practising without a licence, maintaining that he was laughably ignorant of both medicine and astrology. Forman, who declared that celestial signs and aspects gave him all the information about diseases that he required, was fined £5, and interdicted from the practice of medicine. Forman was several times afterwards imprisoned and fined for the illegal practice of medicine. Amongst the medical biographies in this volume, we notice William Webster Fisher (1798–1874), William Henry Fitton (1780–1861), Alexander Fleming (1824–1875), Malcolm Flemyng (d. 1764), John Fletcher (1792–1836), Valentine Flood (d. 1847), Sir Charles Fergusson Forbes (1779–1852), James Forbes (1779–1837), and John Forbes (1799–1823).

New Invention.

A NEW SPONGE ELECTRODE FOR GENERAL FARADISATION.

THE annexed woodcut represents an electrode which I have devised for applying general faradisation. It consists of three parts: a knob (A), containing a female screw, a metal plate from the centre of which rises a male screw (F), terminating in the binding screw (B). A wooden disc (C), on whose lower surface is cut a groove to receive the turned up edge of the plate (G). This disc is cut at its centre in a hole large enough to allow the male screw (F) to travel easily within it. To insert the sponge spread it out flat upon the table, and place the electrode upon its centre, the knob (A) having been unscrewed as far as it will go, and the male screw pushed down, thus leaving a gap between the plate (G) and the wooden disc (C). The relative positions of the electrode and sponge are shown in Fig. 1, which exhibits a side elevation. The edge of the sponge is now tucked in all round with a paper knife into the gap between the edge of the plate and the wooden disc, or body of the electrode, and the knob (A) is screwed well home. To remove the sponge the process is reversed. Fig. 2 shows a section of the electrode with the sponge in position, the edge of the sponge being firmly held between the turned up edge of the plate (G) and the rebate on the under surface of the wooden disc. The sponge must be circular and trimmed to the thickness of about an inch and a half in the centre, thinning to about half an inch at the extreme edge. The advantages of this electrode are: 1. Its size is

Fig. 1.



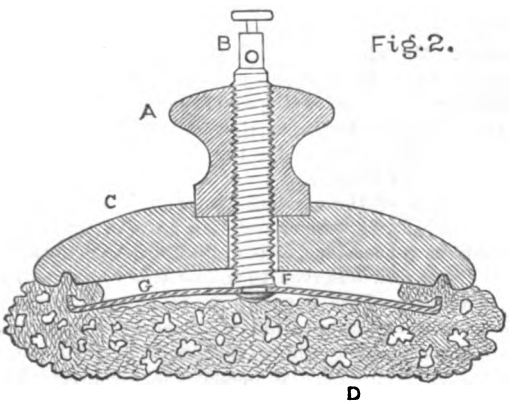


Fig. 2.

large (4½ in. to 5 in. in diameter). 2. The ease with which the sponge can be removed and replaced. 3. Its firmness, which enables a considerable amount of massage to be performed with it. In using it the palm of the hand is placed flat upon the upper surface of the wooden disc, the knob being grasped between the roots of the thumb and forefinger. It is made by Schall, of 55, Wigmore-street, W.

LECTURES ON CHEST DISEASES FOR ADVANCED STUDENTS.

To the Editors of THE LANCET.

SIRS,—May I be allowed to draw the attention of the profession to the fact that the Committee of Management of the City of London Hospital for Diseases of the Chest, Victoria-park, have recently consented, at the urgent request of the medical staff, to allow the practice of the hospital to be made available to practitioners and students, on the payment of a small fee, for systematic instruction in the diagnosis and treatment of chest diseases? The practice is extensive; it comprises a service of 164 beds, and an out-patient department attended by about 14,000 cases a year. There appears to be a considerable demand for post-graduate instruction in the chief subjects connected with clinical medicine, but as the material at our disposal at this hospital is unsurpassed, as far as the subject of chest diseases is concerned, there should be no difficulty in meeting it. For senior students, too, the opportunity thus given of studying a large number of cases of chest diseases must be of great value.—I am, Sirs, yours very truly,

VINCENT D. HARRIS, M.D., F.R.C.P.,
Physician to the Hospital.
Wimpole-street, W., Aug. 5th, 1889.

THE LANCET.

LONDON: SATURDAY, AUGUST 10, 1889.

THE conception of tuberculosis gained by the memorable discovery of the bacillus by KOCH in 1881 is being rapidly pushed to its extreme logical conclusion. For it is remarkable how widespread is the acceptance of the belief, based on that discovery, that this morbid state, which manifests itself in so varied a manner, according to the tissue or organ that is primarily attacked, depends upon the introduction of this parasite into the body. The disease thereby takes a definite position amongst the infective class, since, so far as present knowledge goes, all diseases owning an ultimate cause in an organised virus are communicable. It does not matter for the argument whether—as undoubtedly would appear to be the case with regard to tuberculous affections, and as is probably true of the whole group of specific infective disorders—the victims selected have been already predisposed by heredity, environment, or otherwise to become a favourable soil for the growth of the parasite. This is a question which ought not to enter into the consideration of the preventive measures to be adopted, except in so far as it is necessary to secure that individuals so predisposed are placed under conditions the most favourable for the maintenance of general health. For it is conceivable that under certain transitory conditions an individual not predisposed may yield to the attack of this ubiquitous parasite. No better illustration could be given of the manner in which the bacillary doctrine of tuberculosis now dominates the scientific world than the fact that in Berlin, Paris, New York, and Glasgow there have been recently published declarations, police regulations, reports and judicial decisions, all of which turn upon the acceptance of this doctrine as an assured fact, with the corollary affirmation of the transmissibility of the disease from man to man, and from animals to man. The result is, and can only be, on the admission of this teaching as a proved scientific truth, the enforcement of prophylactic measures of the most stringent kind, such for example as have been widely promulgated during the past week by the Committee of the Paris Congress on Tuberculosis, constituted by many eminent men, an enumeration of which will be found in another column. The policy adopted is "thorough" enough to satisfy the most ardent hygienist; but he indeed would be sanguine who could hope to see even a tithe of these recommendations carried out in practice. For, owing to the complex conditions of civilisation, to the sentiment of humanity, as well as to the affections of the family circle, it is obviously impossible to obey these harsh, if wholesome, dictates of science. In the abstract, doubtless, such recommendations are logical and reasonable; in their application to the prevalent conditions of human existence they will fail by their own impracticability. We talk of the segregation of lepers as the one efficient method for restricting the spread of that scourge of subtropical lands, and perhaps we could realise what that implies if we applied the same measure to subdue the ravages of a disease which in its extent and its fatality ranks far above leprosy. Yet, to be logical, to the one disease should be meted out the same measure as to the other, or the millennium of hygiene will never arrive.

We have stated the matter thus broadly, not because we either mistrust the evidence upon which the conclusions of the Paris Congress were based, or question the validity of these conclusions, but merely in order to point out the practical impossibility of acting upon them. Nevertheless there are directions in which it may be possible to carry out with fair prospect of success the most rigid requirements of the Congress, provided of course that there is good ground for the execution of such measures. It may, indeed, be impossible to protect mankind from tuberculous infection through individuals in the same way as is done in the case of contagious disease generally; but if it be true that much of human tuberculosis is derived from the lower animals, it is at least comparatively easy to close this avenue of contamination. Not long ago it was maintained that bovine and avian tuberculosis were diseases of a nature distinct from human tuberculosis. Even since KOCH'S discovery this contention has been upheld, based now not merely upon gross anatomical differences, but on the infinitely more minute differences in the morphology of the bacilli that are met with in various kinds of animals. However, this view has now been practically abandoned; and, in his recent report to the Agricultural Department, Professor CROOKSHANK dealt it the *coup de grâce*. It appears incontestable that the morbid condition known as tuberculosis is of the same kind in man as in those animals which are specially prone to it, some of which, such as cattle and poultry, form in many ways staple articles of human food. It has been abundantly proved that any portion of tubercular products administered to animals (prone to tubercle) in food or by inoculation will reproduce the disease in the latter; so that it would, with our present knowledge, be an act amounting to a crime to give an infant milk from a cow suffering from tubercular mammitis. Yet who knows how often this has been done in the past, or how much of infantile mortality from tabes mesenterica may be attributable to the direct introduction into the alimentary canal of the parasite—a result which would have its analogy in the induction of an attack of typhoid fever from the ingestion of water contaminated with the typhoid virus or of trichinosis from the ingestion of a piece of raw, measly pork.

The Paris Congress of 1888, of which the Transactions[1] have just appeared, advanced this question a stage further, supporting it by many and forcible arguments, as may be judged by the following resolutions passed at the meeting: "It is imperative that every possible means should be adopted, comprising compensation to parties interested, for the general application of the principle of seizure and general destruction in totality of all flesh belonging to tuberculous animals, no matter how slight the specific lesions found in such animals." (Page 156.) And again: "The Congress expresses the wish that tuberculosis be included in the sanitary laws of all countries in

[1] Congrès pour l'Étude de la Tuberculose chez l'Homme et chez les Animaux. 1re session, 1888. Comptes Rendus et Mémoires. Paris: G. Masson. 1889.

Digitized by Google

the world amongst contagious diseases requiring special prophylactic measures" (p. 716); whilst the French Government, at the very time of the session of the Congress, promulgated a decree enjoining the destruction of carcases in which the tubercular lesions were limited to parts of the body. This is the question which recently excited so much interest in Glasgow, where a judicial inquiry, lasting over many days, was made for the purpose of enforcing the order of the local authority for the destruction of two animals condemned as unfit for human food on account of the presence in them of such limited evidence of tubercular disease. The questions of scientific investigation were submitted to the close analysis of legal advocates, and expert witnesses were called to give evidence on both sides. The views of the Paris Congress prevailed, and KOCH'S bacillary theory, with all its consequences, has received judicial sanction at the hands of Sheriff BERRY, who upheld the local authority, and declared that the flesh (in itself having the appearance of health) of a tuberculous animal is unfit for human consumption. The inquiry was one of great interest and importance, and the evidence given deserves to be widely studied.[2] As it is impossible in the space at our disposal to lay the matter fully before our readers, we propose to return to the subject next week. Meanwhile, it is needless to point out the influence that this decision may have, since tubercular disease in one form or another is perhaps the commonest affection from which cattle suffer; and the general application of the principle therein laid down may necessitate a considerable change in arrangements connected with food supply as well as in sanitation generally.

WE hope that our readers have carefully weighed the facts and arguments so well stated by Mr. HOWARD MARSH in his lectures at the College of Surgeons, an abstract of which we published in our issue of July 27th. There are few, if any, subjects of greater importance to a British surgeon than that of tubercular disease of bones, joints, and glands, and this importance does not arise solely from the number of patients affected, but quite as much from the destructive nature of the disease in many cases, and also from the wide range of variety in course and consequences that it exhibits. The progress of pathological discovery has largely affected the prevalent practice in this branch of surgery. So long as tubercle was regarded as a constitutional affection with local manifestations, treatment was directed mainly to the constitution, and it was regarded as useless to remove a mere local manifestation if the essential disease or morbid condition were left behind. Then came the discovery of the infective nature of tubercle, and the danger of a limited caseous deposit becoming a source of fatal infection for distant organs or for the whole body was impressed upon surgeons, and the expediency of operations for the removal of tubercular deposits was discussed. And when, in 1882, KOCH announced that he had demonstrated the existence of a specific bacillus in connexion with tubercle, a powerful impetus was given to the local treatment of all tubercular diseases. It is, unfortunately, only too true that scientific men, like ordinary mortals, are largely swayed by "fashion." The prevailing "fashion" in modern medicine is a belief in micro-organisms as a potent factor in disease. And so, advancing far beyond what has been demonstrated with proper precision, there are many among us who speak as if micro-organisms were the sole factors in disease and the undoubted cause of all infective maladies. They would also disregard all clinical experience which is opposed to the prevailing pathological dictum. Many recent statements as regards the treatment of surgical tuberculosis show the tendency there is to be influenced by one phase only of pathological truth, and the danger of making a partial view of the nature of a disease a guide in its treatment.

Mr. HOWARD MARSH has done excellent service in calling attention to this matter as regards tubercular disease of the hip, and his lectures ought to have a powerful influence in modifying what may be called the most modern practice in this department of surgery. Mr. CROFT has now for some years been an earnest advocate for early excision of the hip, and has formulated the simple rule that the presence of pus in connexion with morbus coxæ should be taken as a sufficient indication for this operation. Mr. BARKER goes even further than this, and, adopting an explanation for the non-success sometimes attending this practice, which is very common in surgical writings, he states that if evidence of suppuration is waited for the surgeon will often operate only late in the disease, and too late for a full measure of success to attend his efforts. He urges that as soon as the surgeon suspects caseation of the inflammatory products he should proceed to excision of the joint. Mr. HOWARD MARSH, on the other hand, would limit operative interference to the opening of abscesses, and trusts to prolonged rest, with extension and fixation, and general hygienic precautions. He gives statistics to show that the danger of general or distal tubercular infection from bone and joint disease has been exaggerated, and that it is known to occur in only about 5 per cent. of all cases of hip disease. He is strongly of opinion that the tubercular process in bone has a great tendency to be self-limited and to undergo recovery, and that in some cases suppuration is but nature's method of throwing off dead tubercular matters—sequestra he calls them,—and must not be regarded as a destructive process at all. But his case becomes stronger still when from pathological evidence he appeals to actual clinical experience. Against a mortality of 20 per cent. he has to set one of 5 per cent., and while the advocates of early excision have to record a large number of partial successes and shortened enfeebled and distorted limbs, Mr. MARSH is able to show a much higher percentage than they do of strong, firm, fully movable limbs of proper length.

Mr. MARSH might have supported his views by much collateral evidence, particularly perhaps from cases of caries of the spine. He does not in his lectures deal with one argument that is sometimes urged by the advocates of early incision—that of time. They point out that for the wealthy and for the few poor who can obtain admission to institutions such as the Alexandra Hospital, where patients are allowed to stay as long as they require treatment by rest, this rest treatment is all very well. But how about the number of poor who crowd our general hospitals, where a time limit

[2] *Tuberculous Meat.*—Proceedings at trial under petitions, at the instance of the Glasgow Local Authority, against Hugh Couper and Charles Moore, before Sheriff Berry. Glasgow: W. Hodge. 1889.

Digitized by Google

is enforced? Is it not far better to take their cases in hand early and excise the joint and send them home in a month or two than expose them to the perils and disappointments of an imperfectly carried out rest-treatment? This is, of course, an important point, but we cannot admit that it is a satisfactory reply to Mr. MARSH. If the final result of early excision both as to life and to utility of limb were as good as that obtained by prolonged rest, then a treatment demanding only weeks or a few months might be preferred to one involving years, even although a serious operation had to be performed. But the case is not so. The mortality attending early excision at present is four times greater than that following the opposite practice, whilst the mutilation resulting in those who survive is often severe. Of course Mr. MARSH'S vigorous attack will be followed by an equally vigorous defence; and we cannot doubt that the result of discussions of the subject by men so able, so painstaking, and so conscientious, will be of great benefit to the suffering children of our crowded towns.

IN the current number of the *Nineteenth Century*, Dr. BURNEY YEO discusses the well-worn but never uninteresting topic of change of air. There is something suggestive in the mere phrase itself. We do not so commonly speak of change of place or change of scene as of change of air, implying, correctly enough, that it is to an altered atmospheric condition that we look mainly for physical benefit. The German phrases "Luftkur" and "Luftkurort" carry the same implication; and if our faculty for adapting our own language to express new scientific ideas equalled that of our Teutonic neighbours, we, too, might speak of "Air-cure" and "Air-cure-place." Air and food are the materials out of which the organism is built up and maintained, and change of air has a necessity and a utility comparable to variety in diet.

The first kind of change that naturally suggests itself is change from town to country. While Dr. YEO quotes almost with approval the saying of a well-known physician, that he knew "no place so good as London to live in for ten months of the year, and no better place for the other two"; yet we are all practically agreed that a change from the smoky and germ-laden atmosphere of large cities to the pure air of moor, mountain, or seaside is for most persons as necessary as it is undoubtedly pleasurable. Without going the length of the witty philosopher, who opines that

> "All that's great and good in men
> Has its source in oxygen,"

we must admit that without a more abundant supply of oxygen than is afforded by the exhausted atmosphere of our great towns we cannot hope to preserve permanently full vigour of brain and muscle. The delight with which the child hails the departure for the summer resort by mountain or sea, the immense tide of excursionists which flows on each public holiday along the various channels of exit from London and other great centres, the yearly increasing facilities afforded for travel, all tell the same tale of a great need and of the pleasure that attends its satisfaction.

Of the tonic and restorative qualities of sea air, Dr. YEO says truly that nothing new remains to be noted. He goes on to point out the less favourable effects which sometimes follow recourse to the seaside: "Disturbances of the functions of the stomach and liver may frequently be observed in some nervous sensitive subjects when they are dwelling on the seashore, and a seaside dyspepsia accompanied by great nervous depression is not a very rare affection. These disturbances may, however, often be avoided by those who are sensitive to them, by the selection of a coast resort where they can conveniently live at a little distance from or above the sea. It is in those resorts where the visitors have to live on a level with and literally by the sea that these unpleasant consequences are especially observed."

In common with all other authorities, Dr. YEO regards a sea voyage as affording one of the most perfect and healthful types of change of air. He recommends sea voyages "in those cases of anomalous nervous affections, unconnected with organic disease, that are induced by overwork, worry, and anxiety, and often associated with disorder of the digestive organs." Again, "instances of slow, protracted, and incomplete convalescence from acute disease, from surgical operations, &c., are occasionally greatly helped towards complete recovery by a sea voyage, more especially if the persons concerned have a natural fondness for the sea, and do not contemplate the life on board with dread and distaste. To young persons approaching adult age and suffering from debility, the consequences of over-growth, or over-educational strain, or dependent on other depressing influences, a condition which often appears to threaten to terminate in serious disease—to such a long sea voyage is often of essential service."

On these points there will, we conceive, be general agreement. Much more disputable is Dr. YEO'S low opinion of the utility of sea voyages in phthisis. He believes their repute in this affection is almost solely due to the good results which commonly attend a voyage in cases of the debility of adolescence alluded to above, where "incipient consumption" is often erroneously believed to exist. Subtracting such cases, he believes that the residue—i.e., of cases of phthisis decidedly benefited by a sea voyage—is "surprisingly small." This is an opinion so opposed to general experience, and concerns a matter of such vital importance, that it may be worth while to formulate some of the evidence upon which sea voyages are relied upon as a valuable remedial agent in phthisis. Dr. WILLIAMS reports as the outcome of his experience that "the results of sea voyages were that 89 per cent. of the patients improved, 5½ per cent. remained stationary, and 5½ per cent. became worse." He adds the very important remark that "this is the most favourable of all our climatic experiments." Dr. WALSH, after stating that he regards a long voyage as "a remedial measure of real value," goes on to say that "in not a few instances he has known the Australian voyage followed by practical recovery." Dr. DOUGLAS POWELL writes: "The sea voyage is unquestionably a most successful means of climatic treatment in suitable cases." This evidence might easily be multiplied tenfold, so we can hardly follow Dr. YEO in his unfavourable estimate of the sea voyage. We need hardly say that we agree heartily in what he writes regarding "the impropriety, unwisdom, and in some instances the positive cruelty of sending feeble persons, the subjects of advanced consumption, to encounter all the

Digitized by Google

vicissitudes, risks, and occasional hardships of a long sea voyage." This warning is no doubt still necessary.

Dr. YEO concludes with some remarks on the winter resorts, such as Madeira, Las Palmas, Orotava, and the Mediterranean sanatoria. We are quite in accord with all he says about the necessity of being on our guard against the defective hygiene of so many foreign resorts. Happily there is reason to hope that a steady change for the better is in progress in many places.

IT was hoped by the Government that the Notification Bill would come on in Committee on Monday night, when Sir WALTER FOSTER would have had the opportunity of bringing forward his amendment for restricting the duty of the medical practitioner in attendance on an infectious disease to certifying its nature. We cannot regret the delay which will secure attention to the amendment; it should be utilised by all practitioners in urging on their representatives to give it their support. The Government, of course, is master of the situation, and has a very obedient majority at its back. But we still hope that Mr. RITCHIE will consider the great reasonableness of the position taken up by the medical profession. According to Mr. STOREY, the profession cares more for half-crowns than for the merits of this question, and the unfitness of the duties which the Bill as it stands will impose on them. We will not credit Mr. RITCHIE with such an erroneous estimate of the feelings of medical men. We prefer to urge on him the advantage of conciliating them and preserving their hearty interest in the great measure of which he has charge, and which, like others, will redound to the honour of his name. We will enumerate the points which constitute the strength of Sir WALTER FOSTER'S position. The duty sought to be imposed on medical practitioners is an inconvenient and incongruous one. They are a busy class of men, and in attending to one case may have a dozen more needing their prompt attention. In such circumstances it is unreasonable to expect them to notify—that is, forthwith to send a communication to the sanitary authorities with particulars of the case, the patient, his situation, and his responsible relatives. No such duty is required of the medical man in the case of death. He is required to certify the facts. But the transmission of the certificate—in other words, the notification—is left, and with perfect success, to the householder or parent. It is said, of course, that there are not the same guarantees as in the case of death, where interment cannot take place until registration is certified. And there is something no doubt in this difference. But there is not enough to justify, at any rate as a first experiment, the plan of requiring notification from the medical man as well as from the householder. It will be easy enough to add the dual notification if the single fails. But the latter should have a fair trial. And we can promise Mr. RITCHIE that the system shall have every assistance and encouragement from the medical profession, who have never been backward in subordinating their own interests as a profession in the cause of public health. Much is to be gained in this matter by conciliation. The invasion of the privacy of the household and of personal and domestic liberty is a matter on which hot haste and iron compulsion would be unreasonable. Time will in any case be necessary to educate the people to a knowledge of the law and to acquiescence in it; it cannot be borne all at once. Mr. RITCHIE shows his own sense of this in a way that we do not approve. He stops short of making the Act applicable at once to all places. He temporises, and leaves it to the local authorities to accept or reject it as they please. This is scarcely fair; as all the care of one place to secure notification may be frustrated by the carelessness of an adjoining place that refuses to "adopt" the Act. There is too much of this sort of legislation nowadays, as if the House of Commons were timid and distrustful of its own authority. The really wise course is to make the Bill universal in its application, and to secure that the machinery of its working shall be such as to cause least friction. We appeal to Mr. RITCHIE to try single notification first, which is believed by Mr. BIDDLE and others to have been proved to operate most effectively. This concession would secure the passing of the Bill this session, which otherwise might be doubtful.

Annotations.

"Ne quid nimis."

VACCINATION AND SMALL-POX MEMORANDA.

AT the present time, when the value of vaccination as a prophylactic against small-pox is under the consideration of a Royal Commission, a few memoranda, although dealing with well-known facts, may from time to time be conveniently recorded. In the first place, we note that Dr. B. A. Whitelegge gives, in his annual report for the borough of Nottingham, an account of recent small-pox outbreaks which may well shake the faith of those modern enthusiasts who want to rely on irksome and as yet illegal systems of quarantine and isolation, and to abandon vaccination. The first occurrence of small-pox referred to was in December, 1887, in which case nothing was heard of the malady, even under a system of compulsory notification, until a number of people in Nottingham had been infected and the disease had been conveyed to Ilkeston in a fatal form, to Stoke-upon-Trent, as well as to other places. Fortunately, by the aid of vaccination, in addition to measures of isolation, the spread of the infection was stayed. In all, 61 cases are reported on, and the greater comparative incidence of the disease upon unvaccinated persons, and the excessive mortality among that class, were manifested, to use Dr. Whitelegge's words, "in the usual startling way." In the first place, revaccinated persons were entirely exempt from attack. There were 41 attacks amongst those who had been vaccinated in infancy, all but 2 being over ten years of age; of these, 6 died, including a man aged thirty-eight, who bore no characteristic marks of vaccination. Amongst the unvaccinated, 14 were attacked, 9 of the attacks being under ten years of age, and of these 6 died. Six of the patients had been vaccinated after infection, but none of them died. No death of a primarily vaccinated person took place under twenty years of age, whereas half the fatal unvaccinated cases were under five years of age. This question of age-incidence of the disease should altogether dispose of the contention that sanitary improvements lie at the root of the diminution of small-pox in this country, for sanitary influences have, as regards other diseases, been at least as much marked in their influence for good amongst children as in any other class. From Bristol Dr. D. S. Davies supplies information as to 327 cases of small-pox which occurred between August, 1887, and July, 1888. With regard to the incidence of death

Digitized by Google

according to quality of vaccination, the attacks are divided into two groups according as the patients were under or over fifteen years of age. First, as to those under fifteen. In 20 attacks amongst the unvaccinated or doubtful there occurred 11 deaths, this being at the rate of 55 per cent. of the attacks; whereas amongst those having vaccination marks, whether one or more, only one fatal attack occurred, and this was in the case of an infant ten weeks old who had only been vaccinated one week before admission—namely, after contracting the disease. Above fifteen years of age the deaths to attack were as follows:—Amongst 33 unvaccinated or doubtful, 14 deaths; amongst 49 with one or more bad marks, 7 deaths; amongst 18 with one good vaccination mark, no deaths; amongst 78 with two good vaccination marks, 1 death; amongst 39 with three good marks, no death; amongst 22 with four good marks, 2 deaths, one being associated with premature confinement, which is almost invariably a fatal complication; and, lastly, amongst 2 with more than four good marks, 1 death occurred. Thus, whereas out of 82 who were unvaccinated, doubtful, or who had only one or more bad marks, 21 died; there were only 4 deaths out of 159 cases at all ages with one or more good primary marks. Dealing next with the character of the disease as affected by age, it appears that 5 unvaccinated cases were met with under twelve years of age, and all these had the "severe" form of the disease—that is to say, a confluent or semi-confluent attack,—no vaccinated child under twelve years having anything but a "mild" or discrete attack. Above twelve years there were 54 cases of "severe" small-pox, 46 of them being amongst either the unvaccinated or those not possessing more than two vaccination marks. There were 6 cases of hæmorrhagic small-pox; 3 were amongst the unvaccinated, and the other 3 amongst the "badly vaccinated."

"SPONDYLALGIA."

DR. MAX BUCH describes in a preliminary communication to the *St. Petersburger Medicinische Wochenschrift* a nervous cardialgia, the pain in which he discovered to be strictly confined to the anterior surface of the vertebral column, and to be caused by pressure. The pain is so exclusively due to pressure upon the bone that in those of his forty cases in which it was referred to the epigastrium the result of pressure over this region was not merely absence of pain, but rather a feeling of comfort, while pressure on the vertebral column in the umbilical region caused not only local pain, but a neuralgia also, radiating into the epigastrium, and exactly corresponding with the spontaneous pain. Spondylalgia may, according to Dr. Buch, reach as far down as the sacral promontory; in which case, however, some parts of the vertebral column are usually more sensitive to pain than others, or special localities alone are sensitive to pressure. Spontaneous pain also may affect the whole column, and patients often complain during attacks of gastralgia of a pain affecting both sides of the sternum, extending to the clavicle, or over the middle of the chest and the lower half of the sternum. In most of these cases Dr. Buch succeeded in producing the same pain by exerting pressure on certain points of the abdominal part of the vertebral column. Spondylalgia is, indeed, like true neuralgia, apt to radiate from any point over which pressure is made towards some distant points, the pain being not only local but also remote. Dr. Buch believes that he has made out a correspondence between certain points: pressure, for instance, about an inch above the umbilicus generally causes pain in the region of the sacro-iliac synchondrosis, or a little above the sacrum; pressure about an inch below the umbilicus causes pain, radiating into the epigastrium, and especially into the pit of the stomach. In one patient, a woman of forty, pressure in the umbilical region caused a pain like compression in the middle of the vertex, exactly similar to clavus hystericus. Pressure on the spinous process was rarely painful. Other symptoms of spondylalgia are malaise, eructations (often sour), ravenous appetite, or a feeling like that of hunger. The bowels are normal or a little constipated; diarrhœa is rare. In some cases painful pulsation of the abdominal aorta was observed. All the symptoms of spondylalgia most frequently denote general neurasthenia. They also occur in chlorosis and diseases of the uterus. The affection is, pathologically, a neuralgia of the vertebral plexus of the abdominal sympathetic, to which the name "spondylalgia" has been given by Dr. Buch as being short and graphic. His treatment consists in a subcutaneous injection of a 50 per cent. solution of antipyrin into the abdominal region, or, in cases of neuralgia, at the seat of pain. The injection is rather painful, and the puncture if left to itself remains so for many days. If, however, massage is practised immediately after the injection, first lightly and then with some amount of energy, to disperse the liquid, the sensitiveness disappears in about ten minutes. Dr. Buch used the antipyrin injection, according to circumstances, daily or every two or three days. A complete cure occasionally took place after one or two injections, but sometimes only after ten or more. Improvement was generally observed after the first injection. The original affection must, of course, never be neglected, and in chlorosis the spondylalgia has been known to disappear under the administration of iron. He mentions as particularly interesting from the therapeutic point of view cases in which the spondylalgia disappeared under long-continued palpation, so that massage of the abdomen may in some cases be an excellent method of treatment. In conclusion, the author states it as his opinion that the affection is very common, and that every case of cardialgia and dyspepsia ought to be examined for traces of it.

THE MELBOURNE OPERATING THEATRE.

WE learn from the *Speculum*, a journal of the Melbourne medical students, that there are serious defects in the operating theatre of the Melbourne Hospital. It is referred to as "the operating theatre (so-called) of the Melbourne Hospital, which for antiquity and inconvenience stands almost unrivalled as a monumental mausoleum of modern apathy." It is said to be situated on the ground floor, an isolated building with one large room and two small antechambers—one used as an instrument room, the other as a consulting room, and occasionally for the administration of chloroform, the patients having to be deposited on the floor, whilst the doctor in a humble attitude gives the anæsthetic. The entrance doors face the north, and are convenient to receive any stray dust storms; and until lately anyone could see the patients carried across to the room. Patients during transit from any part of the hospital are exposed to the air and wet. "The ventilation of the large room consists mainly of fourteen sets of fixed louvres round the skylight, and conveniently placed to catch the dust, and also soot, from some eight or nine surrounding chimneys. Here it lodges during a calm, to be gently wafted down on the spotless covering of the operating table and patient when on it, much to the astonishment of visitors and annoyance of the operator, should the slightest wind outside dislodge it from its resting place. To complete the ventilation, ordinary ventilators, and four fanlights beneath, which are four grimy ledges sloping downwards into the room, likewise contribute their unwelcome offering when the fanlight is opened." "Night? Two gas circlets of six burners each, o'ershadowed by large reflectors, upon which the dust lies thick; and beneath these the operating table, 'fitted with all appliances, which will not work when required' (a remark by one of the leading surgeons during an operation), receives

Digitized by Google

the patient, who lies unconscious amidst hosts of antiseptic precautions, but happily unaware of the Nemesis above. This is called Listerism in the Melbourne Hospital. The illuminators above being fixed at a definite height, and the gas characteristic of a metropolitan monopoly, the unlucky operator by night has to resort to the dim flicker of a candle to complete a most difficult operation—an actual occurrence." After a description of the present theatre, one is suggested as it should be built, and it will be well if the governors of the hospital take this or some similar plan in hand, and remove what is a discredit to them, replacing it by one in which the skill of the operator is less likely to be baffled by "accidental" complications. We have no report of the result of operations at this hospital, but if the surgeons consider that the mortality is higher than it should be from preventable causes after operations, a united protest would probably effect the desired reform. We cannot think that a wealthy town like Melbourne will long rest under the imputation that it is careless about the welfare of the suffering poor.

THE TREATMENT OF HYDATID DISEASE OF THE LIVER.

DR. DAVIES THOMAS, whose contributions to the study of hydatid disease have been numerous and important, sums up the results of his researches (*Australian Medical Journal*, June 15th) as follows. That there is reason to believe that tapping operations fail to cure the patient in fully 40 per cent. (or more) of the cases in which they have been tried; and that, taking aspiratory puncture and ordinary tapping operations together, the deaths amounted to nearly 18 per cent., but the mortality following aspiratory puncture was only about half that of punctures with an ordinary fine trocar. Speaking generally, the greater the number of punctures required in a given case, the smaller is the probability of cure by tapping alone. Simple puncture, though generally devoid of risk, has been known to cause sudden death, sometimes from shock, sometimes, in the case of pulmonary hydatids, from suffocation by the fluid contents of the bladder-worm. As to parasiticide injections and the use of electrolysis, there is no evidence in their favour that does not apply to simple puncture, whilst each has drawbacks of its own. The mortality of the various forms of radical operation is given as follows: Caustics, 33·68 per cent.; canule-à-demeure, 26·66 per cent.; Simon's method, 48·0 per cent.; Volkmann's method, 19·05 per cent.; Lindeman n's method (abdominal section), 10·29 per cent., and ditto (thoracic incisions) 29·41 per cent. From which it appears that abdominal section yields an even lower mortality than puncture of the cyst.

COUNT PIETRO LORETA.

A FEW hours before he made away with himself, Prof. Loreta sent his annual donation of 500 lire (£20) to the "Society of the 8th August, 1848,"—a day on which a memorable stand was made for Italian freedom and unity, on which, too, Loreta, when a mere youth, had borne his part nobly. In the letter accompanying the donation he said: "Ti mando 500 lire da distribuire ai nostri compagni-poveri. Domani non potrò essere con voi. Ne saprete la causa. Addio!" (I send you 500 fr. for distribution among our poor companions in arms. To-morrow I will be unable to be with you. You will know the cause of this. Farewell!) Although president of the society, his annual gift was, characteristically, anonymous; and the secretary on receiving it, little knew that it was to be the last from the same source. He thought it was the first. A similar experience, say the Italian papers, is in store for the secretaries of countless other charities, of which Loreta was the anonymous benefactor. To the last he was an enthusiastic Liberal in politics, and, though a man of birth and fortune, he was from his youth upwards on the side of the Revolution. When still a student he fought in his country's cause as one of the "Battalion of Hope," and, after risking his life many times in the cholera visitation of 1865 (when, if ever man earned monumental honours, Loreta did), he joined in the year following Garibaldi's army in the Tyrol, and was frequently under fire, when relieving the wounded, in conflicts with the Austrians. His nature was in an exceptional degree ardent, aspiring, and impulsively philanthropic. He was genial, even jovial, to a fault. So highly emotional an organism was not without hereditary neuroses of a specially formidable kind; indeed, his father himself committed suicide, and his brother died an inmate of a lunatic asylum; a family history which points too plainly to the causes that led to his tragical end.

FEMALE MEDICAL AID IN INDIA.

IN the East, thanks to the engrained exclusiveness of social habit, the treatment of women's diseases is to the male physician or surgeon a practical impossibility. Access to such cases is open only to female practitioners. There is consequently a distinct necessity for the employment of medically trained women, and that in a kind of work for which their energies, if not in all points equal to those of men, are as a rule not insufficient. We would be slow indeed to admit the wisdom of employing women in medical duty under all and any conditions. On the other hand, it would be idle to dispute their manifest utility for the purpose in question. Attention has lately been directed to this subject by Sir William Hunter in an article in the *Contemporary Review* on the demand for female medical attendance in India. From the facts here stated it is evident that the aid rendered in sickness by lady practitioners has been much valued by the natives of our eastern dependency. The National Association for Supplying Female Medical Aid, founded in 1885 by Lady Dufferin, has been liberally supported by public subscriptions. The medical tuition which it affords to native women through the medium of the Indian medical schools has attracted a good number of students. Native princes, gentlemen, and the public generally have interested themselves in its growth. Dispensaries and small hospitals have arisen under its auspices and have, during the short period of their existence, done much to relieve the sufferings of the poorer population. The movement therefore is prospering in spite of considerable difficulties. Not the least of these is the want of a vernacular medical literature. This is in course of gradual formation.

A CASE OF SPINAL RESECTION.

IN the *New York Medical Journal* for June 29th Dr. Dawbarn records a case of traumatic paraplegia for which he performed resection of part of the spine. The patient was a man twenty-nine years of age, who fell from a height, striking his lower dorsal spines. On recovering consciousness he was found to be totally paraplegic below the umbilicus, and to have considerable displacement of his eleventh and twelfth dorsal spinous processes. These were replaced as far as possible, and a plaster-of-Paris jacket was accurately moulded on. Some months later he came under Dr. Dawbarn's treatment, the paraplegia not having at all improved. Electrical treatment was tried without permanent benefit, and then, as there was some deformity of the spines, it was decided to cut down on to the spinal cord, and, if possible, remove any portions of bone found to be pressing upon it. An H-incision was made over the seat of mischief, the longitudinal incisions being carried obliquely

Digitized by Google

down and inwards through the muscles on to the laminæ. These were then carefully sawn through, and the intervening mass divided into two by the transverse cut carried down between the two spinous processes. The cord was found to be compressed between the body and laminæ of the eleventh dorsal vertebra, and the laminæ and spines of the tenth, eleventh, and twelfth dorsal vertebræ were entirely removed. The patient made a good recovery from the operation. Ten weeks afterwards he is reported to have been "none the worse for his operation, but, on the contrary, is in many ways somewhat improved, so that he expresses himself as very glad that it was performed." The improvement consisted in restoration of muscular sense, recovery of sensation in the rectum and bladder, freedom from pain in movements of the head and trunk, and improved circulation and temperature in the lower limbs. Before the operation there had been an absence of sweating in the left leg and of all growth in the toenails of the left foot. After the operation the left leg sweated as much as the right, and the toenails grew vigorously. The operation might have been more successful if performed much earlier than after an interval of six months from the primary injury.

THE INTERMARRYING OF CONVICTS.

WITH an optimism certainly not justified by the medico-psychological literature of England, Germany, and Italy, or even of France herself, the French Government has set itself to encourage the intermarriage of life convicts in New Caledonia with life convicts imported from the prisons of the motherland. In official reports published in vindication of these matrimonial arrangements, it is said that "the Government of the Republic is animated in this policy by views of an exalted kind. The constitution of the family in our penitentiaries," the Government apologist continues, "is the best aid to morality. Some of these marriages between two persons whom society has rejected from its midst are prosperous, and such examples, although they are rare, are yet of a nature to warrant the Government in promoting them. The painful exceptions, the number of which has been exaggerated, will tend to become fewer, and the marriages in question will in the long run be better assorted." More than a quarter of a century ago the late eminent Commissioner in Lunacy for Scotland, Sir James Coxe, in an annual report of unusual interest, insisted on the necessity of breaking up and isolating the criminal class as the only way to check the multiplication of crime in our great cities. Forty years' experience in connexion with the Perth Penitentiary had brought Dr. Bruce Thomson to the same conclusion, the soundness of which has derived confirmation from the testimony of numerous Continental alienists, of whom the Italian Lombroso may be adduced as at once the most recent and the most authoritative. "*Simile simili gaudet*," he demonstrates, is nowhere more strikingly illustrated than in the transmission from parents to progeny of depraved habits and felonious proclivities; and his remedy is practically the one recommended by Sir James Coxe, that of separating the individual members of the criminal community as widely and effectively as possible, and of giving them a chance, under saner conditions of association and intercourse, of rehabilitating themselves physically and morally. Vice itself, and, still more, vicious tendency, can be lived down, but only by entire removal from the social atmosphere in which they have been generated, and by steady application of a morally reinvigorating regimen, tested by opportunity and modified by circumstances. With such facts and conclusions *en évidence*, the French Government has surely allowed a sentimental optimism to sway it unduly when it encourages such a system as that recorded by impartial eye-witnesses. "Girls, whether thieves or prostitutes," says M. Moncelon, "on arriving from the prisons of France and landing in New Caledonia are received in a religious asylum, superintended by the sisters of S. Joseph. The rule of this establishment resembles that of a *pension* where the girls draw lots for husbands. On the arrival of a convoy of such young women the bachelors imprisoned in the penitentiaries are in great excitement, and if they ascertain that there are any good-looking ones in the number they demand interviews or introductions. On a fixed day the convict-bachelor is brought into a parlour divided into two by an iron grating. There the sister introduces him to the girl whom he has fancied, and charges herself with the preliminaries, which, beginning with conversation, lead up to a matrimonial engagement." From this not very promising experience the marriage is contracted, with results, according to M. Louis Barron, another eye-witness, the reverse of encouraging. His gleanings, in fact, from the journals of New Caledonia form an instructive commentary on the *lex hæreditaria*, as evolved by Darwin, and are sufficiently adverse to the continuance of an experiment hardly creditable to the countrymen of Esquirol and Pinel, of Paul Broca and Legrand du Saulle.

THE FUNCTIONS OF THE CEREBELLUM.

IS the cerebellum an organ for the storage of cerebral events which have become automatic? Do we first of all receive with the cerebral cortex and then practise with the same brain-bark, and afterwards relegate to the cerebellum, as to a limbo, those things of which we are so tired of being conscious? Are all performances of the cerebral cortex conscious acts, and those of the cortex of the cerebellum unconscious? And so might questions, more or less unanswerable, be postulated without end. The functions of the little brain are scarcely known at all; even the dependence of the equilibrium on its existence may be called in question on the data supplied by pathology. It is perfectly certain that no obvious signs of nervous disease need exist when the lateral lobes are the seat of even extensive mischief. Some regard the cerebellum as the terminal organ of all visceral sensation, and on this assumption it has been thought that the curious perturbations in visceral epilepsy are to be ascribed to perversions of the vitality of the grey matter of the little brain. Anything is possible for the cerebellum. The most gifted imagination might guess strange things, yet pathology could perhaps find exact counterparts.

PUBLIC CONVENIENCES.

THE public conveniences at Piccadilly-circus, which were opened on Wednesday last, the 7th inst., were constructed by the Vestry of the Parish of St. James, Westminster, at a cost of about £3500. The circumstances under which these conveniences were constructed reflect considerable credit upon the Vestry in question, as it was only after a prolonged struggle with, and finally in spite of, the now defunct Metropolitan Board of Works that the Vestry were enabled to provide this much-needed accommodation. The conveniences, which are underground, are divided into two sections, each having a separate entrance from the street, the larger being designed for the use of gentlemen and the smaller for ladies. Both sections are approached from the street by a stone staircase, there being two flights of stairs for the men, one for entrance and one for exit, and a single staircase for the ladies. The accommodation provided in each section appears ample and complete, and the means of ensuring cleanliness in every respect satisfactory. Due attention has also been paid to suitable ornamentation. Ventilation is obtained through fresh-air inlet gratings at the street level and by the entrance staircases. The superstructure consists of a group of ornamental lamps,

Digitized by Google

designed in the free Renaissance style, and raised on a base and dome of polished Aberdeen granite, the lamp acting as a ventilating shaft, and the dome forming a reservoir for the heated or foul air, the upward current being formed in the shaft of the central lamp by means of a small sunlight, which is kept burning at its base. We again congratulate the Vestry of St. James upon the intelligence and enterprise displayed by it in this work, particularly in providing accommodation for ladies—accommodation the absence of which in this great city has long been felt as a crying evil. We may hope that the example thus set will be followed by other vestries.

"PHYSIOLOGICAL ALBUMINURIA."

DR. HANS MALFATTI, of the Laboratory for Applied Medical Chemistry at Innsbrück, controverts the belief that albumen or serum albumen is one of the normal constituents of urine in healthy subjects. He mentions the case of a healthy man in whom the ordinary tests apparently proved the presence of albumen, while Heller's test gave negative results. There was also a singular want of correspondence between the various reactions, as either the test by boiling seemed very satisfactory and acetic acid and ferrocyanide of potassium gave no reaction, or *vice versâ*. Filtration after the test by boiling did not always remove the apparent albumen, which was still discoverable in the filtered urine by ferrocyanide of potassium, especially when chloride or acetate of sodium had been added before boiling. The addition of ferrocyanide of potassium after boiling and adding acetic acid increased the turbidity considerably. When the urine mixed with acetic acid had been allowed to stand, and was then filtered, acetic acid and ferrocyanide of potassium did not make it so turbid, and had sometimes no effect at all, when the same filter was used repeatedly, especially with the addition of acid phosphate of soda, which sometimes prevented the occurrence of turbidity even after a single filtration. After the urine had been treated by reagents which throw down mucin, but not albumen, no albumen could be found, though many tests were tried. The author concludes from his experiments that in the case reported by him albumen was either entirely absent or present in an extremely small quantity only (1 in from 2 to 4 million parts). He considers that the body which has given rise to the supposition that albumen occurs in physiological urine is not an albumen, but a kind of mucin, which is easily broken up into typical mucin and a peptone-like body, and he believes that the presence of albumen in the urine of apparently healthy persons is really indicative of a morbid process, though not necessarily of one of at all a serious character.

HOLDING TO BAIL.

IT often is an exceedingly difficult question whether a person accused of a serious offence should or should not be allowed to give bail, but the ground upon which Mr. Marsham appears to have decided it recently at the Greenwich police court seems very strange indeed to the non-legal mind. The charge was one of murder and came up upon adjournment. Inspector Langrish thereupon asked for a further remand without going into evidence, which the magistrate granted. Thereupon Mr. Besley, who appeared for the accused, asked very naturally to be allowed to give bail. The magistrate objected that the charge was too serious, and that objection we can perfectly understand. Mr. Besley appears, however, to have been able to meet it by citing an instance in which an accused person, who was subsequently convicted of murder, was admitted to bail. Then the magistrate delivered what seems to us a very strange ruling. He is reported to have said that "he had not heard the evidence, and that being so he certainly should not take bail. He would not say that he would be of the same opinion if he had heard the evidence." The report is very meagre, and it may be that the magistrate only meant that he had not heard the evidence given at the original examination. If so, it seems to indicate that the arrangements at the Greenwich police court stand sadly in need of improvement. Surely when the personal liberty of a man who is still entitled at least to the presumption of innocence is in question there ought to be some means of making the depositions taken available for the use of the magistrate who has to adjudicate on that important question, or otherwise of referring the whole matter to the magistrate who is already in possession of the requisite information. If, on the other hand, the meaning is that because no evidence had been adduced that day against the prisoner, the worst ought to be presumed, then surely the rule is repugnant to all the traditions of British justice. In this case the person who is in the unhappy position of being accused is a medical man, and it is easy to see that, even if he should eventually vindicate his character, his present enforced seclusion must do him irreparable harm. Such harm may any day befall the most innocent of men, and, although it would be unreasonable to demand that the administration of the criminal law should be wholly unattended with inconvenience, and even serious inconvenience, to innocent people, it is surely not too much to ask that these inevitable inconveniences should be minimised by an even scrupulous regard for the rights of the individual, rather than aggravated by a perfunctory and reckless watchfulness over the public interest.

THE STRENGTH OF BRAIN FUNCTIONS.

THAT different functions of the brain have different strengths is not always recognised. A violent poison may paralyse the whole of the functions, and the rate at which they become extinguished is so great that it is impossible to say which goes first. In anæsthesia by means of ether the auditory perceptive centres seem to endure longer than the other perceptive centres; indeed, an expansive change appears to occur in them prior to their final closure. What we want to know is something more of the differing strengths of brain functions. This would be a great aid in the study of symptoms. At present the variations in the clinical course and progress of disease are as inexplicable as they are remarkable. That some further experimental researches on the relative strengths of the various nervous functions of the body would bring out facts of importance cannot be doubted.

PRELIMINARY MEDICAL EDUCATION IN THE UNITED STATES.

THE *Medical Record* notices with pleasure the fact that the New York State Legislature recently enacted a law requiring of medical students compliance with a certain standard of preliminary education. The requirements are not very stringent, as our contemporary says, but it is something to see so important a State Legislature legislate on the subject at all, and having put its hand to the plough it will not stop short, let us hope, of doing the work still more effectually. The law requires that "before the regents of the University of the State of New York, or the trustees of any medical school or college within the State, shall confer the degree of doctor of medicine on any person who has not received a baccalaureate degree in course from a duly authorised college or university, they shall require proof that he has passed an examination, under their authority, in arithmetic, grammar, geography, orthography, American history, English composition, and the elements of natural philosophy." It is obvious that unless such requirements

Digitized by Google

are made to apply also to graduates from outside the State, little good will be done. What is wanted is for all the States to agree upon some common legislation that will secure an indispensable amount of general culture and education in the medical profession.

THE TYPHOID GERM.

AT the recent meeting of the American Medical Association, a paper on the Etiology of Typhoid Fever was read by Dr. V. C. Vaughan (*Boston Med. and Surg. Journ.*, July 18th), who alluded to Eberth's discovery of a bacillus, which, although it had been found in most cases of the disease and had been isolated, had not been successfully inoculated in animals. To Koch's four rules for determining the causal relationship of a micro-organism to any disease in which it is found, Dr. Vaughan would add a fifth—viz., that it must be shown that the chemical products of the microbe are capable of producing the characteristic symptoms and lesions of that disease in an acute form. Eberth's bacillus did not respond to any test except that of its frequent concurrence with typhoid fever, and this it was claimed might be explained by its being a result, quite as well as its being the cause of typhoid. Dr. Vaughan had extracted a crystalline ptomaine from this bacillus, and found its injection into the abdominal cavity to produce fever and purging. Dr. Welch, however, thought that the evidence in support of Eberth's bacillus being the cause of typhoid was conclusive, and considered that further evidence was required to establish the belief that the ptomaines obtained from typhoid stools had anything to do with the production of the symptoms.

THE PATRICROFT GUARDIANS AND THEIR MEDICAL OFFICER.

A VERY small dispute between Mr. E. H. Roe, of Patricroft, medical officer of the Workhouse Hospital, on the one hand, and the guardians on the other, has led to his resignation at the request of the guardians, upheld by the Local Government Board after an inquiry by Mr. Henley, held, we are sorry to say, with closed doors. The *Eccles and Patricroft Journal* publishes a letter by Mr. Roe, giving his version of the quarrel, and a leading article on the subject. The dispute between Mr. Roe and the guardians arose in a very simple way. According to his contract with the guardians, he was to find "medicines internal," and they to find castor oil, cod-liver oil, and external applications and appliances. This was a very curious contract, and, as we think, a very unsatisfactory one, very different from the system in vogue in London, where medicines are supplied by the guardians. But small as the undertaking of the guardians was, they quarrelled over it with Mr. Roe. When he required substances for external application, however urgently, he had to wait till the next meeting of the board before they could be supplied. The guardians denied his right to order what external applications he thought fit, and only recognised his right to order such as his predecessor used to order. This is obviously a most absurd limitation. The crisis came in this manner. Mr. Roe told the chemist to have certain things he wanted ready when he should receive the order of the board. Instead of waiting for this the goods were at once despatched. But Mr. Roe did not use them. No less than five weeks elapsed before he could get from the clerk any information as to the board sanctioning the order of the drugs. Mr. Roe pressed the clerk, and pencilled a line to him saying that "a patient's death had been accelerated for the want of the medicines." This note was shown to the guardians, and was taken as a reflection on them, though it was meant only to stimulate the clerk, who said "he had forgotten" to bring the list of drugs wanted before the board. Mr. Henley defended Mr. Roe in regard to most of the points on which he was charged, but held that he had disobeyed a legal and reasonable direction of the guardians in "ordering" the drugs before the meeting of the board, though Mr. Roe had not ordered them, but only told the chemist to have them ready. We think that after such delays he should have ordered and used the drugs absolutely, and that the guardians should have indemnified him. If the saving of a patient's life or the mitigation of his sufferings in dying were involved, it was not a case for delay. We never heard of a medical officer being dismissed on so slight and doubtful a ground, and we earnestly hope that the guardians of their own motion will reconsider their attitude towards Mr. Roe. We have only one qualification to make. We are writing on Mr. Roe's version of the facts. But thi comes of the inquiry being with closed doors.

TREATMENT OF PNEUMONIA BY APPLICATION OF ICE.

DR. FIEANDT, writing in *Duodecim*, a Finnish medical journal, states that he has now treated no less than 106 cases of pneumonia with ice, and with the best results. Though ten of the cases were of double pneumonia only three out of the whole number succumbed, notwithstanding that the epidemic was by no means a slight one. The method adopted was to apply over the affected lung an india-rubber bag containing ice continuously for from twelve to twenty-four hours after the crisis. In addition to the local treatment the patients were given such medicines as are usually employed, that is to say, opium, ipecacuanha, digitalis, brandy, &c. The method has, we may remark, received of late some attention in this country.

PERSONALITIES IN JOURNALISM.

AN evening contemporary has lately had a very strong pronouncement on the "virtues of the greatest surgeon in the world in operations pertaining to certain diseases of women." He has a singularly sweet and pleasant expression, &c. Best of all, "he has now made a fortune," in spite of many cases where he is too generous to take a fee. It is difficult to say whether his fame is greatest in England, Germany, or the United States. The point of all this laudation — which is extended also to a favourite pupil, described as having a fine face and quiet, gentle manner, &c.—seems to be reached in an expression of the hope that the "greatest surgeon," in consideration of his fortune, will be able at the next election to offer himself to a constituency in which the political views held by our contemporary prevail.

ŒDEMA OF THE BRAIN.

ACCORDING to Dr. Hugenin of Zurich inflammatory œdema of the brain or diffused encephalitis occurs after perforating wounds of the skull with injury to the brain, also in tumours of the brain where the centre breaks down and softening is going on towards the periphery, also in abscess and infectious diseases of the brain, and more rarely in cases where there is hæmorrhage or a hæmorrhagic infarct. It is, however, to the non-inflammatory variety of cerebral œdema that Dr. Hugenin has devoted his attention specially. Having made a large number of post-mortem examinations in cases of this kind, he has come to the conclusion that so long as the vessels within the cranial cavity maintain their normal condition, there is no fear of any fatal œdema resulting from circulatory disturbance in cerebral disease; but when there exist such morbid conditions as obliteration of the lymphatics or increased intra-cranial pressure, due to diminution of the cranium or more par-

Digitized by Google

ticularly to an arrest of its ordinary growth, fatal œdema of the brain may be induced. He found that in children who had died from hyperæmia or œdema of the brain or slight hydrocephalus there was commencing meningitis, usually of an infectious character—that is to say, due to the presence of streptococci. Fatal congestive œdema in children was found to occur only when there was obliteration of the channels leading from the space beneath the pia mater or obliteration of the Pacchionian bodies, such as is set up in the course of chronic meningitis.

LARYNGEAL ULCERS IN TYPHOID FEVER.

DR. ANTONOFF publishes in the *Ejenedêlnaya Klinicheskaya Gazeta* the result of a series of histological examinations of laryngeal ulcer occurring in typhoid fever. The earliest change, he says, is a hyaline degeneration of the membrana propria of the capillaries and smaller arteries, and in places of the connective tissue of the mucous membrane. The epithelium dies from coagulative necrosis. The reticulum formed becomes the seat of micrococci. There is no inflammatory infiltration in the broken-down tissue, but the process takes place on the border between healthy and morbid tissue. If the ulceration goes deeper perichondritis with formation of pus, phlegmonous inflammation of the soft parts, and loosening of the fibres of the cartilage take place.

THE LIVERPOOL POISONING CASE.

AFTER a protracted trial, and evidence of a full and minute character, Florence Maybrick was found guilty at the Liverpool Assizes last Wednesday of the wilful murder of her husband, by administering arsenic, and sentence of death was passed in the usual form. Owing to the unusual circumstances surrounding it the case has excited widespread interest, an interest perhaps not equalled since the hearing of the curiously similar Madeleine Smith case, which was tried in Edinburgh in July, 1857, but which ended in a happier manner for the accused than did that of the unfortunate woman condemned to death on Wednesday. The case turned largely upon the medical evidence, and it is that with which we are mainly concerned. This evidence, as our readers will be aware, was conflicting and contradictory, and in view of the extreme gravity of the case, we shall have to reserve our analysis of the medical evidence until our next issue.

PATHOLOGY OF EXTENSIVE BURNS.

OSCAR SILBERMANN of Breslau finds that in extensive burns the red corpuscles alter their form, and are able to exert less than their normal resistance to heat, drying, compression, and staining. In consequence of these changes thrombosis and stasis in different organs are very frequent, especially in the lungs, kidneys, stomach, bowels, spleen, liver, skin, and brain, and most of all in the smaller branches of the pulmonary artery. The stasis in the lungs produces a very considerable impediment to the emptying of the right ventricle, with enormous venous congestion and dangerous arterial anæmia. This again leads to apoplexies and parenchymatous alterations in the above-mentioned organs, also to dyspnœa, cyanosis, coma, a small pulse, angina pectoris, eclampsia, anuria, and to a diminution of the surface temperature.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—Dr. Rosenheim has been recognised as *privat-docent* in Medicine.

Buda-Pesth.—The nominations of the Professorial Senate to several of the professorships vacant have not been accepted by the Minister of Education. It is, however, stated that the chair of Special Pathology and Therapeutics has been definitely filled by the appointment of Dr. Karl Kétli.

Naples.—Dr. Romano has been recognised as *privat-docent* in Operative Medicine.

Padua.—Dr. Canalis has been recognised as *privat-docent* in Hygiene.

Pavia.—Dr. Zambianchi has been recognised as *privat-docent* in Operative Medicine.

Rio de Janeiro.—Dr. João Paulo de Carvalho has been appointed Professor of Physiology.

Turin.—Dr. Gradenigo has been recognised as *privat-docent* in Midwifery.

Zurich.—Dr. Felix of Würzburg has been appointed Prosector of the Anatomical Institute.

THE report on the composition and quality of the metropolitan water-supply during the month of June by Messrs. Crookes, Odling, and Meymott Tidy shows that of the 168 samples examined 6 were recorded as "very slightly turbid." The remaining 162 samples were found to be clear, bright, and well filtered. During the month of June the progressive increase in degree of freedom from organic matter, manifested by the water-supply during the first five months of the year successively, was not found to be sustained; but there was, on the contrary, a retrogression to about the degree recorded as prevailing a month or two back. Dr. Frankland, in his analysis, states that, taking the average amount of organic impurity contained in a given volume of the Kent Company's water during the nine years ending December, 1876, as unity, the proportional amount contained in an equal volume of water supplied by each of the Metropolitan Water Companies and by the Tottenham Local Board of Health was:—Kent, 0·8; Tottenham, 1·0; Colne Valley, 1·2; Grand Junction, 1·5; New River, 1·6; Lambeth, 2·0; West Middlesex, 2·6; East London, 2·7; Southwark, 3·4; and Chelsea, 3·8.

AT the Edinburgh University, on capping day, as will be seen by the list, published in another column, of successful candidates for degrees and of prizes and scholarships awarded to distinguished graduates, the Cameron Prize in Therapeutics was conferred on M. Pasteur in recognition of the high importance and great value to practical therapeutics of the treatment of hydrophobia discovered by him.

ACCORDING to telegraphic advices from Zanzibar, fever is very prevalent among the fleet, the English apparently suffering most. On the *Agamemnon* alone, out of a total complement of 400 men there are eighty sick, including seven officers. The deck had been turned into a hospital, and hammocks were slung everywhere.

IN reply to a deputation to urge the Australian Government to assist in an attempt to remedy the defective hospital accommodation in Melbourne, Mr. Gillies has agreed to ask Parliament to give a grant of £10,000 towards the foundation of a hospital, and to consider the question of a contribution towards its maintenance.

THE Italian Medico-Psychological Congress (Congresso Freniatrico) will this year be held at Novara, within easy distance of Turin and Milan, from Sept. 8th to the 14th. These Congresses are triennial, and there have already been five of them.

AT Rome the great Hospital of the Santo Spirito is about to open a *succursale* (branch) near the Bocca della Verità for the accommodation and treatment of chronic cases.

THE HEALTH OF THE ARMY IN 1887.

No. III.

THE average strength of the European troops in India (exclusive of the force in Upper Burma) was 63,942; the admissions were 1351, the deaths 14·68, the mean sick 70·45, and the invalids sent home 22·60 per 1000—all except the invaliding lower than in 1886, and except the mean sick considerably under the decennial average.

In Bengal, a force of 40,921 had 1404 admissions, 15·00 deaths, 69 65 mean sick, and 10·90 invalids discharged per 1000, all, except the invaliding, lower than in the preceding year. Malarial fevers were the most frequent cause of admissions (amounting to upwards of one-fourth of the whole), and enteric fevers of death, cholera being the next. The admissions at the various stations ranged from 723 at Solon to 2623 per 1000 at Saugor, where the great excess was due to malarial fevers. The deaths, omitting stations where the force was under 150, and the hill depôt at Naini Tal, where the results were affected by the number of men arriving from Burma, ranged between 4·02 per 1000 at Solon and 34·14 at Nowgong, the latter due chiefly to cholera. Enteric fever gave rise to 13·1 admissions and 4·06 deaths per 1000 of strength. Lucknow was the station which furnished the greatest number of cases and deaths, amounting to 79 and 16, but there were few stations entirely free from it. As usual, the great prevalence of the disease was among the younger soldiers. The admissions were highest in the second and the deaths in the third quarter of the year. The deaths were in the proportion of 1 in 3·24 cases. Cholera prevailed to a considerable extent, the admissions amounting to 3·3 and the deaths to 2·25 per 1000, chiefly in the third quarter of the year. The stations most affected were Peshawar, Meerut, Rhaniket, Lucknow, and Allahabad, and also troops on the march. Two of every three cases terminated fatally. Venereal diseases, including all forms, caused 324 admissions, and the constantly non-effective from these amounted to 22·32 per 1000. Three cases of hydrophobia occurred, all of which died, one at Saugor, one at Naini Tal, and the third at Dalhousie. The most frequent cause of invaliding to England was the group of diseases of the circulatory system, amounting to 2·98 per 1000 of strength. Of 122 cases, 37 were returned as palpitation. In the Bengal command, the cavalry had the highest ratio of admissions and mean sick and the artillery of deaths. The sickness was greatest among the men at the ages of twenty to twenty-four, and also the death-rate, with the exception of those from thirty-five to forty. Among the officers the cases of sickness amounted to 684, the deaths to 10·24, and the invaliding to 29·86 per 1000, considerably lower than among the men, except the invaliding, which was one-half higher. Among the women the admissions were 783, and the deaths 16·96 per 1000, and among the children 562 and 52·62 per 1000.

In the Madras Command the admissions from an average force of 11,738 were 1242, the deaths 13·80, the mean sick 77·26, and the discharges by invaliding 13·37 per 1000, being considerably lower than in 1886. Venereal diseases were the most prevalent, and those of the digestive system the most fatal in the Command, the latter causing nearly one-fourth of the deaths. Omitting the depôts, the highest ratio of admissions was at Thayetmyo, and, at stations having a force over 150, of deaths at Madras and Pallaveram, but it is stated that both these results were considerably affected by the arrival of sick from the troops on field service in Burma. The admissions by enteric fever were 12·3 and the deaths 2·98 per 1000, the disease being most prevalent and fatal in the third quarter of the year. Secunderabad furnished much the largest number of cases and deaths, and next to it Bangalore. The prevalence of the disease at Secunderabad was attributed to the 7th Hussars having recently arrived from England, and having a large proportion of young men in it; "the barrack and latrine accommodation was also reported to be defective." At Bangalore the cause could not be definitely traced, but was believed to be attributable to the bad sanitary conditions of the bazaars, where the men "drink bad water, mixed or otherwise. There were only 8 cases of cholera and 7 deaths; 4 of them occurred at Secunderabad. The admissions by all forms of venereal disease were 350 and the constantly non-effective 27·39 per 1000. The high death-rate by diseases of the digestive system was due to hepatitis and abscess of liver, the admissions by which were 27·26 and the deaths 3·15 per 1000. By arms of the service the infantry had the highest ratio of admissions and mean sick and the lowest of deaths, while the deaths were highest and admissions lowest in the cavalry. In the invaliding to England, 2·90 per 1000 were sent home on account of the circulatory system—a ratio almost identical with that from Bengal. Among the officers the cases were 834, the deaths 10·16, and the invalided 98·30 per 1000; the last, though very high, was slightly lower than in 1886. Of 29 thus sent home, 12 were on account of fevers, 7 debility, and 5 hepatic affections. The women had 1002 cases and 17·52 deaths per 1000; and the children 856 and 54·09 per 1000.

The water-supply of Fort St. George is reported as unsatisfactory, and the latrines and drains require improvement. The water at Bangalore is also unsatisfactory, requiring to be boiled and filtered a second time before use by the troops. At most of the other stations it is reported as abundant and good.

The average strength of British troops in Bombay was 11,283; the admissions were 1274, the deaths 14·45, the mean sick 66·30, and the discharges by invaliding 12·32 per 1000 of strength. The admissions and mean sick were considerably under, but the deaths and invaliding slightly above the proportion in 1886. The admissions ranged between 2058 per 1000 at Ahmedabad and 775 at Deolali; and the deaths between 59·52 at Neemuch and 4·27 per 1000 at Hyderabad. The excessive mortality at Neemuch was due to an outbreak of cholera. The admissions by enteric fever were 11·3 and the deaths 3·37 per 1000 of strength. Mhow furnished much the largest numbers of cases and deaths, the former having been 56 and the latter 13 out of a total of 127 and 38, but no specific cause for this could be ascertained. The disease also prevailed to a considerable extent at Nasirabad, Karachi, and Ahmednagar. Cholera was the cause of an admission-rate of 3·5 and a death-rate of 2·48 per 1000. Of 39 cases and 28 deaths, 23 and 17 occurred at Neemuch in the third quarter of the year, and 8 cases with 5 deaths at Mhow. No cause is assigned for the outbreak, nor is any information given respecting the measures adopted to check it, or the removal of the troops into camp, if that were done. The admissions for venereal diseases, including all forms, were 287 per 1000, and the constantly non-effective from it 20·59, both lower than in the other two Presidencies. The highest ratio of admissions and mean sick was in the cavalry, and of deaths in the artillery; the infantry had the lowest of admissions and deaths. Among the officers the cases amounted to 612, the deaths to 8·42, and the invaliding to 61·80 per 1000. The women furnished 717 cases and 16·01 deaths, and the children 576 and 53·40 per 1000.

The number of recruits medically examined during the year was 60,976, or about 14,000 less than in 1886. The number rejected was 27,571, or 452 per 1000 examined, being 19 per 1000 higher than in 1886. There were 51,884 primarily inspected by army medical officers, with a ratio of 458 per 1000 rejected, and 9092 by civilian medical practitioners, with only 210 per 1000 rejected; but of those passed by the latter, 1919, or 267 per 1000, were subsequently rejected, giving a ratio of 421 rejected of the number primarily inspected. In addition to the total rejected at inspection there were 249, or 4·08 per 1000, discharged as unfit within three months after enlistment. But as we have frequently pointed out, some of the causes of rejection were not medical but military, such as under-height and over-height, under chest measurement, and apparent age not in accordance with General Orders. If these be deducted from the numbers inspected and rejected the proportion found unfit on medical grounds would be 318, as against 312, per 1000 in the preceding year. Of the recruits finally passed into the service, 763 per 1000 were natives of England and Wales, 96 of Scotland, 129 of Ireland, and 12 of British colonies and foreign countries. From the tables in the report, "it has been calculated that, excluding boys under seventeen years of age, the average age of recruits finally approved during the year was 19·6 years, the average height 5 ft. 5·8 in., the average weight 126·2 lb., and the average chest measurements 33·8 in. These all show an improvement upon the results for 1886. As regards education, the returns show an increase in the "well educated," but attended with a reduction in those able to read only, while the "unable to read" remains exactly the same as in the preceding year.

In the appendix to the report we observe with much satisfaction that Surgeon-Major Notter, the Professor of Military Hygiene at Netley, has resumed the annual review of the progress of hygiene introduced originally by Professor Parkes, but which has been in abeyance since 1882. To these reviews we always attached much importance, and Dr. Notter has done well to inaugurate his professorial career by re-establishing them. In addition to notices of works bearing on hygiene, he has given a full detail of the work done under his superintendence at the laboratory at Netley. Among other things this included an analysis of 89 samples of water, of which 36 were found "fit for use," 26 usable or requiring filtration before use, and 27 unfit for use on account of organic impurity, and of excessive hardness and chlorides. The details of these are given in a tabular form. There is also a report of bacterial cultivations from these samples of drinking water by the assistant professor, Surgeon A. M. Davies. The conclusion at which he arrived was that "no opinion apparently can be expressed as to the character of a drinking water from the rough bacterial testing as here recorded." But the number of observations is small, and Mr. Davies is continuing them in the hope of obtaining some definite result. In addition to these, a course of experiments was made on the filtration of water, and a considerable number of analyses of different samples of concentrated and preserved foods, milk, and wine, the results of which are given in some detail. The amount of work done and the careful manner in which the results are reported are very creditable to this branch of the Netley School, and if properly utilised by those in authority, ought to prove very beneficial.

The usual list of operations performed at the hospital during the year, with short abstracts of the most important cases, has been furnished by the assistant professor, Brigade surgeon Goodwin. The same officer gives a very good report of the transactions of the French Congress of Surgery at Paris in March, 1888, which he attended officially as the representative of the British Army Surgeons. The appendix also contains an abstract of a topographical report on the Pichin valley by Surgeon-Major Burry, M.D., and several cases by Army medical officers. But for these we must refer our readers to the volume itself, the whole appendix to which is deserving of study.

THE PROPHYLAXIS OF TUBERCULOSIS.

WE have been requested by the Standing Committee to publish the following "Instructions to the Public, to enable it to know and be capable of protecting itself against Tuberculosis."[1] The document was communicated to the Academy of Medicine on July 30th. When it came on for discussion at the meeting of the Academy on Aug. 6th, the document was submitted to severe criticism, especially by Drs. G. Sée and Dujardin Beaumetz, the latter declaring there was no evidence that tuberculosis was propagated through meat. Other speakers also criticised the recommendations in Clause 6, and eventually the debate was adjourned to the 13th inst.

I. Tuberculosis claims more victims in towns and even in certain rural districts than any other disease. Thus, in 1884, for example, of 56,970 deaths in Paris about 15,000, or more than one-fourth, were due to tuberculosis. The tuberculous are so numerous because pulmonary phthisis is not the sole manifestation of tuberculosis, as has been erroneously believed by the public. Physicians have good ground for considering as tuberculous many other diseases besides pulmonary phthisis. In fact, a number of cases of bronchitis, catarrhs, pleurisies, croup (gourmes), scrofula, meningitis, peritonitis, enteritis, white swellings (osseous and articular), and cold abscesses are tuberculous diseases as formidable as pulmonary phthisis.

II. Tuberculosis is a parasitic disease, virulent, contagious, transmissible, caused by a microbe—the bacillus of Koch. This microbe penetrates into the organism by the digestive canal with food, by the air-passages with inspired air, by the skin and mucous membranes following sores, punctures, wounds, and various kinds of ulceration. Certain diseases—measles, small-pox, chronic bronchitis, pneumonia; certain constitutional states due to diabetes, alcoholism, syphilis, &c.,—greatly predispose the individual to contract tuberculosis. The cause of tuberculosis being known, the precautions taken against its germs are capable of preventing its propagation. We have an encouraging example in the results obtained in respect to typhoid fever, the epidemics of which diminish in all towns where steps have been taken to prevent the typhoid germ mingling with drinking water.

III. The parasite of tuberculosis may be met with in the milk, muscles, and blood of animals serving for the food of man (ox, cow especially, rabbit, poultry). Raw or underdone meat and blood, being capable of containing the living germ of tuberculosis, should be prohibited. Milk, for the same reason, should only be consumed after being boiled.

IV. Owing to the dangers arising from milk, the protection of young children, who are so readily attacked by tuberculosis in all its forms (since there die annually in Paris more than 2000 tuberculous children below the age of two years), should especially engage the attention of mothers and nurses. The ideal is of course lactation by the healthy woman. A tuberculous mother should not nourish her child. She should entrust it to the care of a healthy nurse living in the country, where, under the best hygienic conditions, the risks of tuberculous contagion are much less than in the towns. The child thus brought up will have a great chance of escaping tuberculosis. If suckling at the breast be impossible, and it has to be replaced by feeding on cow's milk, this milk, given to the infant by the bottle or spoon, should always be boiled. The unboiled milk of asses and goats is far less dangerous.

V. Owing to the dangers arising from butcher's meat, which may preserve all the characters of health even when the animals are tuberculous, the public is largely interested in being assured that the inspection of meat, required by law, is properly and generally practised. The only absolutely certain means of avoiding the dangers of meat coming from tuberculous animals is to cook it to such an extent that the deep parts are as well done as the surface; only thoroughly roasted, boiled, or fried meat is devoid of danger.

VI. On the other hand, the germ of tuberculosis, being capable of transmission from the tuberculous to the healthy subject by sputa, pus, dried mucous discharges, and all objects laden with tuberculous dust, it ought, to ensure security from the transmission of tuberculosis, to: 1. Be known that the sputa of the phthisical being the most formidable agents for the transmission of tuberculosis, there is a public danger in distributing them on the soil, carpet, hangings, curtains, napkins, handkerchiefs, cloths, and coverings. 2. Be well understood, in consequence, that the use of spittoons should be imposed everywhere and upon everybody. These should always be emptied into the fire and cleansed with boiling water; they ought never to be emptied on dust-heaps, or in gardens, where they may tuberculise the poultry, nor into the latrines. 3. Not to sleep in the bed of a tuberculous subject; to dwell in his room as little as possible, and especially not to suffer young children to sleep there. 4. To remove from places, inhabited by the phthisical, individuals regarded as predisposed to contract tuberculosis, subjects born of tuberculous parents, or having had measles, small-pox, pneumonia, repeated attacks of bronchitis, or suffering from diabetes, &c. 5. Not to use objects which may have been contaminated by the phthisical (linen, bedding, clothing, objects of toilet, hangings, furniture, toys) except after previous disinfection (high pressure steam, boiling, sulphur vapour, lime-washing). 6. To ensure that the rooms of hotels, lodging-houses, châlets, or villas occupied by the phthisical in watering-places or winter resorts are furnished and carpeted in such a way that disinfection may be readily and completely effected after the departure of each patient; the best plan would be that these rooms should have neither curtains, carpets, nor hangings; that they should be painted with lime, and the floor be covered with linoleum.

The public is mainly interested in preferring hotels in which such indispensable hygienic precautions and measures of disinfection are carried out.

[1] These instructions have been drawn up by the Standing Committee of the Congress for the study of Tuberculosis, consisting of MM. Chauveau (President), Butel, Cornil, Grancher, Landouzy, Lannelongue, Legroux, Leblanc, Nocard, Rossignol, Verneuil, Villemin, L. H. Petit (Sec. Gen.). They have been seen and approved by MM. Bouchard, Brouardel, Potain, and Proust.

THE PARIS UNIVERSAL EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT.)

The International Congress of Hygiene.

THERE are so many congresses now sitting in Paris that it is physically impossible to follow them all. Last week we had the congresses on Alcohol, on Poor Relief, and on Therapeutics. This week we have the congresses on Mental Medicine, on the Amelioration of the Condition of the Blind, on Zoology, and on Hygiene and Demography. The last-named is undoubtedly the most important of all these gatherings. Its labours were inaugurated on Aug. 4th, and there were at that time 662 members, of whom 134 were foreigners, and represented 28 different nationalities. Among the latter there were 10 English, 10 Italians, 14 Russians, 6 Roumanians, 8 Spaniards, 4 Swiss, and 22 delegates from the North and South American continents. Further, it is to be noted as a gratifying symptom that the various municipalities, almost all the municipalities of the large towns of France, have sent special delegates. The opening ceremony took place in the large Amphitheatre of the Ecole de Médecine, which was gracefully decorated with drapery and flowers for the occasion. The Congress is held under the honorary presidency of the Minister of the Interior, and Dr. Brouardel occupied the chair. Dr. Chantemps, president of the Paris Municipal Council, and Sir Douglas Galton sat on either side of the chairman. The platform was crowded with the representatives of different nationalities, and the large amphitheatre was completely filled by the members of the Congress. A considerable number of ladies, many of them members of the Congress, also assisted. Dr. Brouardel, who was warmly greeted when he rose to speak, related how within thirteen years French hygienists had been received abroad five times, at Brussels, Turin, Geneva, the Hague, and Vienna. All had retained an ineffaceable souvenir of these great meetings, and he hoped that at our present Congress and on the pacific field of hygienic study fresh victories would be achieved. Alluding to the Faculty of Medicine, where the Congress met, he spoke on the immense changes that had been brought about. Here it was that medical men had struggled against barber-surgeons, and had sought to maintain the exclusiveness of their profession. Yet here it was to-day that medical men welcomed engineers, chemists, architects, public administrators, and not only welcomed them, but were even anxious to consult them and to follow their advice. Not only was this a mighty change, but it was precisely this that constituted their principal force. It was because hygiene united so many different professions that it had acquired so much strength and popularity. Hygiene had swept away the old ramparts that had kept various professions apart, and it would also help to unite different nationalities. The discussions, which were formerly restricted to the academies, had now invaded the Parliaments, and "the President of the French Republic, justly inspired by the interests of the Democracy, of which he was the highest and the most respected representative, had inscribed reform in the sanitary services among these reforms which must receive the first attention of the Legislature." This announcement was received with loud applause. Dr. Brouardel then proceeded to describe the difficulties of the Legislature when sanitary measures were proposed, as they almost invariably interfered with some vested interests. These interests soon organised resistance against the proposed reform. The expense and difficulty of reform was a certainty, while the danger to be avoided was often unrecognised or doubtful in the mind of the public. Then there was always some doctor or other who supported the old ideas, and thus strengthened the reaction. The Governments were often sorely perplexed. But such congresses as the present armed the sanitary reformers with an expression of competent opinion which no administration could afford to discard. Dr. Brouardel then described some of the progress already achieved, and concluded by rendering homage to Dr. Napias and Dr. Martin, who had so ably organised the Congress, and the younger secretaries who had assisted. Paraphrasing the "Marseillaise," he said, "Vous entrez dans la carrière lorsque vos ainées y sont encore." Our generation has forged the arms; it is for the next generation to use them.

Sir Douglas Galton was then called upon to speak, and, in the name of Professor Corfield, Mr. Shirley Murphy, and the other English delegates, thanked the Congress for the reception given them, and for the honourable position he (Sir Douglas Galton) occupied at the presidential table. He regretted deeply the absence of his eminent colleague, Sir Edwin Chadwick. Dr. Alfred Carpenter had once remarked that the influence of a sanitary inspector in preserving the health of a community depended on the degree of education of that community concerning the laws of hygiene. The mission of the English sanitary societies represented at this Congress was to spread the knowledge of hygiene at home and abroad. In Paris especially they were called upon to admire the progress made, and envy the intelligent manner in which the principles of hygiene were applied to daily life. The next Congress, it had been decided, would be held in London. They would do their best to show their foreign visitors how in England sanitary principles were practically applied. He hoped the French hygienists would attend in large numbers, and promised them a hearty welcome in London.

Senator Dr. Pacchiotti, on behalf of Italy, delivered an eloquent oration. He dwelt on the delight of the foreign delegates when invited to visit the country which had done so much for humanity, and which to-day had organised a universal exhibition that was the marvel of the world. He described how Italy, enlightened by the example of France, had created at the Ministry of the Interior a service of hygiene. This consisted of a director of hygiene, a medical man, and a committee of hygiene, organised under the Minister of the Interior at Rome. These watch over the public health of the entire kingdom, while at each provincial prefecture there was a similar director of hygiene aided by a committee to watch over local interests, and to communicate with the central bureau at Rome. Dr. Pacchiotti then, in warm, glowing language, showed how Italy and France, as two sisters, had progressed hand in hand, how the works of M. Pasteur, of Emile Trélat, and of Durand Claye had been appreciated in Italy, and how many Italian municipalities had imitated the example of Paris in creating a municipal laboratory for the prevention of the adulteration of food. In the future, as in the past, France and Italy would continue to struggle for freedom, for civilisation, home, country, and humanity. This speech, which was ornamented by many flowers of rhetoric, was very enthusiastically applauded.

Senator Dr. Crocq, official delegate of the Belgian Government, related what had been done in Belgium to organise the sanitary services, and maintained that it was the duty of every Government, whatever its origin and form, to forward the interests of the people, and the first of these interests was the preservation of their health. For this purpose private interest, if necessary, must be sacrificed. A healthy people cost less and produced more. The question was an international one, for with the modern and rapid means of communication and exchange one nation was sure to suffer from the neglect of sanitary matters by a neighbouring nation. He therefore congratulated the Congress on its international character and on having met in France, the land of freedom, and in Paris, the capital of progress.

Dr. W. Dextererv, delegate of the Russian Society of Public Hygiene, briefly but warmly expressed the sympathy of Russian sanitary reformers with the French nation and the efforts of French hygienists. He was greeted with applause of a very special and marked character.

Dr. Felix of Bucharest rendered homage to the great sanitary reformers whom he had met in Paris at the Congress of 1878, and who were now dead; mentioning the names of Bouchardat, Gübler, Fauvel, Durand Claye, Lionville, Paul Bert, Würtz, and Tardieu. He closed by a graceful compliment to the President of the Republic, M. Carnot, and the President of the Congress, Dr. Brouardel.

Señor M. Belmas, on behalf of the Spanish Delegation, described the progress achieved in Spain and the decrease of the death-rate in that country. He showed that a system of sanitary administration was being organised on the French model, and that those countries, late in reform, might ultimately become the healthiest, through the adoption of the most recent and perfected methods.

Dr. Chantemps insisted that a reduction in mortality always followed on the rigorous application of sanitary measures. As administrators, they had come to the Congress to learn. In the study of hygiene, a sentiment of generous

Digitized by Google

solidarity united the representatives of every nation, and nowhere were words of international fraternity more welcome than at an international sanitary congress.

Dr. Napias, as secretary of the Congress, read a lengthy report on its organisation, containing the facts and statistics as to the Congress already given. He concluded by expressing his thanks for the active support the cause and the Congress had received at the hands of the press, and especially the representatives of foreign scientific journals.

Dr. Chantemps having felicitated the Congress on the presence of so many ladies, Dr. Roth urged that the Ladies' Sanitary Association was the first society of the sort that had been formed, and then the Congress adjourned to other apartments, where refreshments were served, and many friendly acquaintances renewed.

On Monday morning the various sections of the Congress met, and several resolutions were adopted. In the first section there was an important discussion on measures that should be taken in schools to prevent the spread of phthisis by the sputa of youths suffering from tuberculosis. Dr. Jablonski, a Russian delegate, would exclude every pupil who might be suspected of tuberculosis, but this proposal found no support whatsoever from the members of the Congress. Dr. Felix of Bucharest energetically urged that when there was abundant expectoration and no doubts entertained as to the nature of the malady, then the young person—for this would rarely apply to little children—should be excluded from school. There could be no doubt that the sputa were a cause of infection; and therefore the education of one child had better be sacrificed instead of endangering the health of a whole school. Dr. C. Drysdale urged that the question was too wide in its bearings to justify the Congress in jumping at a conclusion. Personally, he had twenty years' experience of hospital treatment of phthisis, and had failed to remark that the nurses and other attendants contracted tuberculosis; and they were far more exposed to the contagion than school children, even if one or two among the latter were in an advanced stage of consumption. Other speakers protested against the danger of spreading unnecessary alarm, urging that cases where "suspicion" only existed should be subject to confidential communications between the school and the family doctor. Suggestions were also thrown out as to the necessity of providing spittoons, and preventing children soiling the floors of schools; but these were very generally considered impracticable. Finally, the section adopted the following resolution: "That children who undoubtedly are suffering from pulmonary tuberculosis may render the adoption of measures prescribed by the authorised medical attendant necessary for the preservation of the health of the school." Practically the question is left to the discretion of the school doctor, who may take measures, such as the exclusion of the pupil, when he thinks there is a real risk of contagion.

In the afternoon an important discussion took place in Section 5 on the report presented by Dr. Proust, inspector-general of the sanitary services, on Sanitary Works in Seaport Towns. The report concluded: "(1) That it was the strict duty of Governments and municipalities to render ports healthy; (2) that sanitary works for seaport towns were more necessary than for other towns; (3) that it was only when such sanitary works had been accomplished that any notable reduction in the death-rate and zymotic death-rate would take place; (4) that it was only when the ports presented a soil unsuitable for the penetration of morbid exotic germs that the last quarantine checks could be abolished." The discussion was limited to the first two clauses. No speaker made any allusion whatsoever to the question of quarantine. A very mild discussion was held as to whether the State, the municipality, or the chambers of commerce could best secure the application of the necessary sanitary measures, and then the vote was taken, and a favourable decision unanimously given. The chairman now rose to vacate the chair, but Mr. Adolphe Smith protested that, in common with many others, he had only voted in favour of the first two or three clauses of the resolution, and did not understand that the question of quarantines had yet come before the section. Most of the delegates had, however, already risen to leave. A confused conversation followed, and it was understood that the question would be re-opened on another occasion. The last clause of the resolution practically means that quarantines should be imposed everywhere, for what port is there in the world where it is possible to declare that the soil is absolutely incapable of harbouring the germ of an imported disease? This is evidently a subject which the Congress must more carefully discuss.

In the afternoon Section 1 debated the able and interesting report of Dr. Landouzy and Dr. H. Napias on the Best Means of Protecting the Health of Children. Dr. Desmoulin of Ghent said that whereas the mortality among rich children ranged from 10 to 20 per cent. that of the poor varied from 30 to 60 per cent. At Ghent the children working in factories, from the age of eleven, showed terrible signs of physical degeneration. He urged that mothers should receive such help as would enable them to leave the mill at the period of childbirth. Many of the speakers denounced poverty as the principal cause of a high rate of mortality, but several delegates were afraid that by restricting the work of children this poverty would be increased. Mr. Adolphe Smith, on the contrary, pointed out that it was precisely the competition of the work of women and children that reduced the scale of wages. The British coal miner was better paid than the Belgian miner; but in Belgium the women and children worked below ground in the coal mine. The discussion was ultimately adjourned.

On Tuesday morning the report of the French Government Commission on Unwholesome Dwellings was discussed at great length. The conclusions of M. Hudelo, the reporter, were combated in a report drawn up by M. Jourdan. The principle at stake was whether the Commission on Unwholesome Dwellings could deal with the question, or whether, as proposed by M. Jourdan, special salaried inspectors should be appointed to inspect houses and insist on sanitary improvements. The Commissions of Insalubrious Dwellings had rendered great service. At Bordeaux, for instance, they had visited 1800 houses in one year. Would a paid agent have the same moral influence? The commissions were composed of doctors, architects, and engineers, who received no remuneration, and whose opinion was therefore respected. Householders would be more likely to contest the decisions of a mere paid inspector. M. Jourdan insisted that the Commissions which had done good work existed only in large towns, and could not be created in smaller districts. Dr. Pacchiotti remarked that as two sanitary laws were now before the French Parliament, it would be better to wait till their fate was decided. An American delegate related that paid sanitary inspectors in America did their work well, while Mr. Adolphe Smith also alluded to the work done by the sanitary inspectors in England acting under the medical officers of health. The difficulty in France was not to discover insanitary houses, but to find a wholesome dwelling. According to the admirable charts shown at the Exhibition by M. Masson, there were not 2000 sanitary houses in Paris, but about 96,000 insanitary houses. A large handsome room did not make a healthy house. Every house with soil pipes untrapped was unhealthy. It was first necessary to decide what constituted a healthy house. This had been done in Brussels but not in France.

Dr. Janssens, Chief of the Brussels Sanitary Bureau, then explained how, by applying the French law of 1789 and 1790, immense progress had been achieved, and the death-rate reduced from 30 to 22 per 1000. Any complaint led to an inspection, and on report of inspectors the mayor ordered the necessary improvements. If these were not at once executed, the house was declared unfit for human habitation, emptied, and closed. The tenants then prosecuted the landlord and claimed damages for disturbance; consequently the landlords now always and promptly carried out the improvements ordered by the mayor at the suggestion of the sanitary inspectors and bureau. The Congress ultimately unanimously decided that the French law of April 13th, 1850, on unwholesome districts, should be revised. This revision was in the sense of rendering the appointment of commissions on insalubrious districts obligatory throughout France. Some delegates preferring M. Jourdan's proposal, voted against this, but it was carried. Another resolution was adopted unanimously, raising the cubic space per inhabitant from fourteen to sixteen cubic metres, and a final resolution in favour of establishing sanitary bureaux in all towns was approved.

In the afternoon of Tuesday Section 5 discussed the treatment and removal of domestic refuse, what in England is familiarly known as the dust-bin nuisance, but in France is called *la boite à Poubelle*. The discussion in the main was very French in character. Thus it was shown that, in Paris,

Digitized by Google

where there was little or no cinder, but, on the contrary, a larger quantity of vegetable refuse, the town refuse was worth from 3f. 50c. to 4f. the cubic metre. The reporter on the question, M. Dumesnil, insisted principally on the method for the removal of the refuse, and the resolution carried was to the effect, "That domestic or kitchen refuse should be placed in a metal box or case, which was to be kept clean and disinfected; that it was desirable that the box or case destined to receive the refuse of the entire house should be placed at the disposal of all the tenants in the evening; should be kept in a part of the building where there was a plentiful supply of air; should be provided with a lid easily removed, and kept in a cellar or other place where there is a ventilating shaft." It will be seen that this latter part of the clause only applies to certain towns and houses. Another resolution, to the effect that all refuse should be put outside the dwellings before night and removed daily, was a more sensible proposal to make at an international congress, for it involved principles rather than details of execution, and was carried unanimously and without discussion. In the course of the afternoon it was remarked that in England the contractors were paid to remove the refuse, while in France profits were made. Mr. Shirley Murphy pointed out that the practice in different districts varied, and that it was impossible, without knowing every detail, to compare the one with the other; but where the cost of collection from the houses had to be borne by the contractor, he was paid in London large sums of money for this service. The principal new point raised was the question often put but never satisfactorily answered, whether house refuse could be partially dried and then packed under strong hydraulic or other pressure. Thus reduced in bulk, partially dried (that is, lessened in weight), it would cost much less to transport to distant agricultural districts, where a more ready market would be found.

To-morrow, at 7 A.M., the whole Congress proceeds to Reims, and the next sitting will be held on Thursday.

Paris, Aug. 6th.

MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE annual meeting took place at the rooms of the Medical Society of London on Thursday, July 25th, when the President, Dr. Hayes Newington, delivered an address on Lunatic Asylum Hospitals, of which the following is an abstract.

Dr. NEWINGTON gave credit to Dr. Batty Tuke and Mr. Brudenell Carter for having re-started the discussion, and referred to the article in *The Times* of April 30th, 1889. He showed that the original idea was embodied in sec. 27 of 8 and 9 Vic., c. 126, but it was not followed up and has since been repealed. He vigorously contested the depreciatory account that had been given of the progress in the study of insanity during past years. From the point of view of the efficacy of treatment he showed that 40 per cent. of admissions were cured, and that the balance of admissions contained an enormous proportion of hopeless cases. Eighteen per cent. of all admissions are general paralytics or epileptics; 21·8 are aged fifty-five or over; 22 per cent. are admitted after a year's duration of the disease; and a further 13 per cent. after three months' duration. Looking to the number of such cases, either dead or dying in intellect, the accumulation of chronic cases in asylums could no more be charged with a failure to overcome "brain death" than could the accumulation of a cemetery be laid to the door of general medicine. He uttered a warning that highly coloured statements would procure a refusal on the part of the public to provide hospitals, which are undoubtedly wanted not only for the purpose of gradually increasing our recovery rate if possible, but for teaching insanity to students, as well as for the more elaborate and leisurely study of the disease by professed alienists. The danger is that the public would either take as true all the hard things said, and would refuse to entrust medical men with further and expensive institutions, since they cannot properly use those already under their charge; or the public would, on finding out the real facts, consider that it had been needlessly alarmed by exaggeration, and would be disposed to sleep over the matter. He deprecated any idea that his arguments should be taken as signs of ultra-conservatism on the part of alienists. Alienists, like other scientific persons, looked for improvement; but justice had to be done both to present and past workers in the field of insanity, and the public itself had interests which would be imperilled if it were led to form erroneous opinions as to the present condition of psychiatry. He advocated the establishment of two classes of hospitals; the first to form part of the machinery of county and borough asylums, into which all curable cases should be taken and kept for a certain time, unless, of course, recovery took place; the second to be erected near large towns supporting medical schools. Both are to be under the responsible charge of alienists, but both are to have the advantage of the services of general physicians. In the latter class of hospitals ample provision is to be made for systematic and clinical teaching, much on the lines of a general hospital. He gave considerable details as to the arrangements, the selection of cases, and the duties and relations of the staff.—A discussion followed, in which Drs. Clouston, Savage, Hack Tuke, Yellowlees, Rayner, Whitcombe, Urquhart, Mr. Clark Bell, and others took part.

THE BRITISH NURSES' ASSOCIATION.

THE annual meeting of members was held in the Guildhall, Cambridge, on Wednesday, July 31st, Professor Humphry, F.R.S., in the chair. The hon. secretary, Dr. Bedford Fenwick, read the first annual report, which spoke of an amount of success achieved by the Association which at the inception of the scheme was hardly hoped for. Founded only upon Dec. 7th, 1887, there were already 2537 members enrolled in addition to the branches forming in the Australasian colonies and South Africa, which would add several hundreds to the numbers of the Association, whilst financially the Association was in a most prosperous condition. The subject of registration had been most carefully and thoroughly considered, and the best advice had been taken. In the interests alike of the public and of qualified nurses, and for the protection of both, the General Council had decided to act upon its own initiative, and to open without delay registers of nurses and midwives, and to place on these at once without payment the names of members of the Association. For a few months to come all who had been engaged in nursing for three years and possessed unexceptionable testimonials of knowledge and character would be eligible for registration. But after that brief period of grace and thenceforward only those women who produced certificates of training from a recognised nursing school or diplomas from an obstetrical body would be entered on the registers. When a sufficient number had been enrolled, the General Council proposed to present the petition for a Royal Charter to Her Majesty the Queen in Council. It might be added that the Royal Charter had now been drafted, and, except for some verbal alterations which might hereafter be made, was practically already prepared. Amongst other schemes to be undertaken by the Association was the establishment of a benevolent fund to assist members standing in need of temporary pecuniary assistance. A number of resolutions in accordance with the objects of the meeting, and making requisite alterations in the bye-laws &c., were put and carried, and the proceedings, which were marked throughout by considerable enthusiasm and entire unanimity, came to a close, the members dining in the hall of St. John's College, the vice-chancellor of the University being in the chair.

ARMY MEDICAL SCHOOL.

THE summer session of the Army Medical School was brought to a close on the 2nd instant at Netley. Ten candidates for commissions in H.M.'s Indian Medical Service had passed through the courses of practical instruction at the school. No candidates for commissions in the British service attended during the session, but twenty-four surgeons of the medical staff had gone through a post-graduate course. Sir Dyce Duckworth, M.D., F.R.C.P., accompanied by Director-General W. A. Mackinnon, M.S., C.B., and Surgeon-General Sir Joseph Fayrer, K.C.S.I., F.R.S., arrived from London to distribute the

Digitized by Google

prizes, which were delivered to the successful competitors, as usual, in the lecture theatre in the presence of the medical and military staff of the Royal Victoria Hospital, professors of the school, and a number of visitors. After handing the prizes with a few appropriate remarks to each recipient, Sir Dyce Duckworth delivered an address, which is printed in full on another page. At the close of the address the Director-General spoke, referring to the time when he was himself among the number of the professorial staff of the school, and he was followed by Sir J. Fayrer, who gave the young surgeons about to proceed to India some valuable counsel derived from his own long experience in that country, and heartily congratulated them on having selected service in India for their future professional career. At the conclusion of the proceedings in the lecture theatre, the meeting adjourned to the officers' mess-room, where luncheon was served.

We publish in another column the list of successful candidates for commissions in the Indian Medical Service, and the number of marks gained by them, together with the names of the surgeons to whom prizes were awarded.

MALCOLM MORRIS INDEMNITY FUND.

THE following additional subscriptions to the above fund have been received:—

	£	s.	d.
Amount previously acknowledged	428	7	0
Sir William Gull	5	0	0
D. J. Woodman, Esq. ..	5	5	0
Dr. Corfield	2	2	0
Dr. M. Barnes	1	1	0
Dr. T. Morton	1	1	0
Dr. Allchin	1	1	0
W. J. Walsham, Esq. ..	1	1	0
Dr. Macnaughton Jones	1	1	0
E. Nettleship, Esq. ..	1	1	0
Herbert W. Allingham, Esq.	1	1	0
Dr. Henry C. Martin ..	1	1	0
Dr. H. Cooper Rose ..	1	1	0
Dr. Riding	1	1	0
Dr. T. Britton (Harrogate)	1	1	0
Bruce Clarke, Esq.	0	10	0

The costs amount to £480. Subscriptions may be sent to Mr. G. P. Field, 34, Wimpole-street, or to Dr. Sidney Phillips, 21, Upper Berkeley-street, who will be glad to receive subscriptions which have been promised but not yet sent.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Fatal "Croup" &c. in the Horwich Registration District, by Mr. J. SPEAR.—Another of those prevalences of diphtheria, of a more or less marked type, masked under such names as "croup" &c. has occurred in the Horwich registration district. The term diphtheria having been more freely used towards the end of 1887 and the beginning of 1888 than during the earlier part of the prevalence, the matter at last came under the notice of the Local Government Board, and Mr. Spear was instructed to inquire into the occurrence. It now appears that between the beginning of 1884 and the end of the first quarter of 1889 an outbreak causing no less than 57 deaths took place in this registration district, all but 3 of the deaths being registered in the Horwich and in the Westhoughton urban districts, having together an estimated population of some 214,000 persons. Of 26 fatal attacks up to the end of 1887, only one was registered as diphtheria, the remainder being described under such terms as croup, tracheitis, cynanche trachealis, and laryngitis. And of 27 deaths in 1888 only 4 were put down to diphtheria. The subjects were nearly all young children, and in 3 of the "croup" cases membrane is said to have been visible either on the pharynx or as the result of expectoration. In dealing with the cases that came within review Mr. Spear says that in the more obvious general symptomatology little differentiation was found possible between the fatal affections, whether described as croup, tracheitis, or laryngitis; and speaking again of non-fatal attacks, he says that on the whole the testimony available suggested that under such names diseases of a different etiology had been included, and that although in some half-dozen cases the history was that of diphtheria, yet the non-fatal attacks were rarely in the same neighbourhood, or apparently associated with the fatal attacks. It is next pointed out that the 38 fatalities ascribed to "croup, tracheitis, and laryngitis" occurred in 35 different households, in 26 of which no other similar attack, or, indeed any of diphtheria or noticeable sore-throat, occurred, although they contained some 78 other children or young people; and we rather infer from this that Mr. Spear inclines to the view that these cases were in some respects different from diphtheria. But the exceptional cases show that what is termed "laryngitis" led to multiple attacks in the same households, whether of the same complaint or of what is termed either sore-throat or croup; that when diphtheria of a typical type took place this was followed by so-called croup; that croup cases were followed by other croup cases; and that diphtheria in one case attacked an adult who had been nursing a croup patient. The truth is, that there is nothing so very exceptional in genuine diphtheria being limited to single attacks in households; its power for spread being at times very different from that which obtains at others. Indeed, of six fatal attacks from "diphtheria" reported by Mr. Spear, three were single ones, whereas two occurred in houses where fatal attacks of croup had taken place, the remaining one being associated with two mild attacks in the family invaded, and probably with two or three elsewhere. Mr. Spear next adverts to the coexistence of measles and scarlatina with some of the fatal attacks registered as croup or laryngitis, a coincidence which he is inclined not to regard as accidental. Looking to the whole of this statement about throat illness, fatal and non-fatal, forming apparently an epidemic, we cannot help thinking that an almost artificial attempt is made to differentiate between the several diseases. Whilst we would by no means deny the possibility of occurrences of laryngitis or of croup, merely because a diphtheria prevalence was in progress, yet we cannot help thinking that the knowledge we have recently acquired as to the natural history of diphtheria goes to show that all which occurred during the prevalence under consideration is entirely consistent with the view that throughout the disease met with was diphtheria, in so far as that term can be regarded as covering a single specific disease, the affection merely manifesting certain of those modifications, alike as to local symptoms, power of spread, and otherwise, which are known to have marked its course in outbreaks where no question whatever has arisen that it was diphtheria and no other disease, that was met with.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5770 births and 3763 deaths were registered during the week ending Aug. 3rd. The annual rate of mortality in these towns, which had been 21·0 per 1000 in each of the preceding two weeks, declined to 20·5 last week. During the first five weeks of the current quarter the death-rate in these towns averaged 20·3 per 1000, and was 0·1 above the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 14·1 in Brighton, 14·8 in Birkenhead, and 15·7 in Bristol and in Huddersfield. The rates in the other towns ranged upwards to 25·9 in Newcastle-upon-Tyne, 27·0 in Manchester, 28·8 in Sunderland, and 42·6 in Preston. The deaths referred to the principal zymotic diseases in these towns, which had been 1018 and 998 in the preceding two weeks, further declined last week to 891; they included 578 from diarrhœa, 79 from measles, 69 from whooping-cough, 65 from diphtheria, 59 from scarlet fever, 41 from "fever" (principally enteric), and not one from small-pox. These zymotic diseases caused the lowest death-rates last week in Wolverhampton, Derby, and Huddersfield, and the highest rates in Salford, Sunderland, Plymouth, and Preston. The greatest mortality from diarrhœa occurred in Salford, Sunderland, Birmingham, Leicester, and Preston; from measles in Plymouth, Newcastle-upon-Tyne, Leeds, Halifax, and Preston; from scarlet fever in Huddersfield, Bolton, and Plymouth; from whooping-cough in Portsmouth and Sunderland; and from "fever" in Preston. The deaths from diphtheria included 45 in London, 5 in Manchester, 3 in Salford, and 3 in Sunderland. Small-pox caused no death in any of the twenty-eight great towns; and no small-pox patient was under treatment at the end of the week either

Digitized by Google

in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and London Fever Hospitals at the end of last week was 727, against numbers increasing in the preceding five weeks from 559 to 660; 124 cases were admitted to these hospitals during the week, against numbers increasing from 33 to 110 in the previous seven weeks. The deaths referred to diseases of the respiratory organs in London, which had been 141 and 160 in the preceding two weeks, further rose last week to 182, but were 11 below the corrected average. The causes of 76, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Norwich, Plymouth, Wolverhampton, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Birmingham, Halifax, and Liverpool.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·6 and 17·9 per 1000 in the preceding two weeks, rose again to 18·3 in the week ending August 3rd; this rate was 2·2 below the mean rate during the same week in the twenty-eight large English towns. The rates in these Scotch towns ranged last week from 12·4 and 12·7 in Dundee and Perth to 25·2 in Leith and 27·4 in Paisley. The 468 deaths in the eight towns showed an increase of 9 upon the number in the previous week, and included 39 which were referred to diarrhœa, 15 to whooping-cough, 8 to measles, 7 to "fever" (principally enteric), 4 to scarlet fever, 4 to diphtheria, and not one to small-pox; in all, 77 deaths resulted from these principal zymotic diseases, against numbers increasing from 81 to 95 in the preceding four weeks. These 77 deaths were equal to an annual rate of 3·0 per 1000, which was 1·9 below the mean rate from the same diseases in the twenty-eight English towns. The deaths referred to diarrhœa, which had risen in the preceding five weeks from 17 to 41, declined to 39 last week, but exceeded by 17 the number in the corresponding week of last year. The 15 fatal cases of whooping-cough showed a decline of 6 from the number recorded in the previous week, and included 6 in Glasgow and 3 in Edinburgh. The deaths from measles, which had been 18 and 20 in the preceding two weeks, declined to 8 last week, of which 3 occurred in Edinburgh and 2 in Aberdeen. The 7 fatal cases of "fever" exceeded by 3 the number in the previous week, and included 5 in Glasgow. Of the 4 deaths attributed to diphtheria, 2 occurred in Leith, and of the 4 fatal cases of scarlet fever, 2 were returned in Glasgow. The deaths referred to the principal diseases of the respiratory organs, which had been 66 and 59 in the preceding two weeks, were 60 last week, and slightly exceeded the number in the corresponding week of last year. The causes of 54, or nearly 12 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased from 16·3 to 24·8 per 1000 in the preceding three weeks, declined again to 20·7 in the week ending Aug. 3rd. During the first five weeks of the current quarter the death-rate in the city averaged 21·5, the mean rate during the same period being 18·2 in London and 16·4 in Edinburgh. The 140 deaths in Dublin showed a decline of 28 from the number in the preceding week; they included 8 which were referred to diarrhœa, 4 to measles, 2 to "fever," 1 to whooping-cough, and not one either to small-pox, scarlet fever, or diphtheria. Thus the deaths from these principal zymotic diseases, which had been 25 and 23 in the previous two weeks, further declined to 15 last week; they were equal to an annual rate of 2·2 per 1000, the rate from the same diseases being 3·7 in London and 2·3 in Edinburgh. The deaths referred to diarrhœa showed a further decline from those recorded in recent weeks; the fatal cases of "fever" and of whooping-cough were also fewer than those registered in the preceding week. The deaths of infants showed a marked increase, while those of elderly persons were below those recorded in the previous week. One inquest case and 1 death from violence were registered; and 47, or more than a third, of the deaths occurred in public institutions. The causes of 16, or more than 11 per cent., of the deaths in the city were not certified.

INFANT AND CHILD MORTALITY IN MOSCOW.

The city of Moscow now issues a monthly return of mortality statistics, which is a sign, at any rate, that its inhabitants are supplied with the means of testing its sanitary condition by its death-rate. It appears from these returns that the population of the city in 1882 was 753,469, and not far short of that of St. Petersburg. Estimating the present population of the city at 800,000, the annual birth-rate during the first five months of this year was equal to 41·3 and the death-rate to 37·2 per 1000; these rates are probably understated by an over-estimate of the present population. The official return not only gives the deaths at different age periods, but also the ages of the population at the same groups of ages. From this it appears that the proportion of children in the population was remarkably small. The proportion of children aged under five years of age is stated to have been in 1882 only 60 per 1000, whereas in London the proportion living in 1881 at these ages was 130 per 1000. This small proportion of living children in Moscow may be partly due to the remarkably high rate of infant mortality that appears to prevail there. During the first five months of this year the deaths of infants aged under one year in Moscow were equal to 389 per 1000 registered births, whereas in London this proportion of infant mortality did not exceed 124, or less than a third of the rate in Moscow. The death-rate among children aged between one and five years does not show so large an excess as does that of infants under one year; but, based upon the ages of the Moscow population given in the return, the annual death-rate of children aged under five years in that city, in the five months under notice, was equal to 138·6 per 1000, and was more than double the recent death-rate at these ages in London. As throwing some light upon this startlingly high death-rate of children in Moscow, we may point out that the returns before us show death-rates from "fever," diphtheria, scarlet fever, measles, and diarrhœa enormously exceeding those recorded in English towns. We must content ourselves with noticing that the annual death-rates from diphtheria and diarrhœa in Moscow during the five months ending May last were equal to 1·01 and 6·12 per 1000, whereas the rates from those diseases in London during the same period did not exceed 0·31 and 0·20 per 1000 respectively. Thus diphtheria was more than three times and diarrhœa more than thirty times as fatal in Moscow as in London. With reference to the mortality from diphtheria in Moscow, it should, moreover, be stated that the deaths referred in the five months to croup and to "pneumonia crouposa," both headings classed among the principal zymotic diseases, considerably exceeded those returned under the heading "diphtheritis."

HEALTH OF MEXICO.

Dr. Daniel Kuiz, of Vera Cruz, has recently drawn up a report on the mortality in the canton of Vera Cruz, from which we learn that the most prevalent diseases are those affecting the lungs. Miasmatic diseases account for only 164 deaths out of 1101 last year in the city itself, but they were responsible for an immense amount of sickness, which did not prove fatal, but which considerably lowered the general standard of health. Lung diseases and paludal fevers are so general that one has only to pass down a crowded street to see their effects in the contracted chests, anæmic complexions, and thin limbs of the passers by. Even the police, who are a picked body of men, are characterised, though in a somewhat less degree perhaps, by the same evidences of the effects of the treacherous climate. The cargadors (porters) are, physically speaking, the finest class, possessing broader chests and better developed limbs than the great majority of the population. The reasons of this physical superiority are threefold: (*a*) the cargador's work, while it lasts, is severe, and weak persons are not admitted into the brotherhood; (*b*) the cargador is well paid and well fed; (*c*) he takes sufficient physical exercise in the open air, which with the other classes is, in consequence of the climate being so hot, damp, and enervating, the exception rather than the rule. Another cause of the weak chests and the anæmia which are so prevalent may be found in the custom which obtains of very early marriages. The climate is again at fault, for it develops both sexes very early, and girls are sometimes wives at fourteen and mothers at fifteen, whilst marriages at sixteen are not at all unfrequent. These early marriages are not unprolific, but the children of them are, as a rule, weakly, the mortality amongst them is great, and the survivors help to lower the general standard of health.

"Audi alteram partem."

VACCINATION AND INFANTILE SYPHILIS.

To the Editors of THE LANCET.

SIRS,—With your kind permission I wish, albeit somewhat late in the day, to make one or two remarks on a matter which press of work prevented me from taking up at the proper time, but which has again cropped up in your leading article of July 27th. I refer to the argument derivable from Scotch registration statistics regarding the relationship between vaccination and infantile syphilis, and to Dr. Creighton's connexion therewith.

The argument, as I have put it in "Vaccination Vindicated," pp. 136–38, is, in three parts, briefly as follows:—1. Opponents of vaccination hold that because deaths from syphilis have largely increased in the first year of life, "the year of vaccination," the increment is to a great extent due to that operation. Regarding this, the question at once arises, Have the deaths taken place mainly before or after the performance of "the rite"? The answer is to be found in the tables of the Scotch Registrar-General, in which the first year of life is divided into three periods: 0–3 months, 3–6 months, and 6–12 months. Here are the figures for three recent years:—

Deaths from Syphilis in Scotland at certain Ages.

Year.	0 to 3 months.	3 to 6 months.	6 to 12 months.	1 to 2 years.	All ages.
1882	109	44	39	16	244
1883	107	51	23	16	240
1884	117	57	26	14	276
Totals	333	152	88	46	760
Per cent. ..	43·8	21·3	11·6	6	100

But in Scotland vaccination is not compulsory until six months, so that of deaths from syphilis at all ages this table shows that no less than 65 per cent., or about two out of every three, take place before the age of vaccination; and in the second half year of life, when vaccinal syphilis ought to be rampant, the deaths fall to 11·6 per cent., or less than one-fifth of those in the prevaccination half year. 2. If vaccination were responsible for any considerable part of the infantile syphilitic mortality, then, as the operation is compulsory three months earlier in England than in Scotland, the former country should, in the first half year of life, have a correspondingly higher share of the deaths But in the same three years the percentages were, under six months, 64·5; from six to twelve months, 11·3; and from one to two years, 6·1. The remarkable similarity of these figures to those given above, shows that vaccination has nothing whatever to do with the comparative syphilitic mortality of the two countries. 3. The powerlessness of vaccination to propagate syphilis may be shown even more clearly. Anti-vaccinationists have pointed out that the mortality has risen more rapidly under one year than at all ages combined. The question again is, In what part of the first year has the increase occurred? The Scotch registrar once more gives the answer. (The Vaccination Act of Scotland was passed in 1863.)

Deaths from Syphilis in Scotland, 1855–9 and 1880–4.

Five years.		Under one year of age. 0 to 3 months.	3 to 6 months.	6 to 12 months	All other ages.	All ages.
1855–9.	Deaths ..	142	81	42	116	381
	Per cent. ..	37·3	21·3	11·0	30·4	100
1880–4.	Deaths ..	540	242	147	284	1213
	Per cent. ..	44·5	20·0	12·1	23·4	100

Thus the deaths from syphilis have grown from 381 to 1213, an increase much more rapid than that of the population. Further, the population under one year formerly contributed only 70 per cent. of the total, and now it contributes 77 per cent. Seven per cent. has thus been transferred to "the year of vaccination." But, on looking at the figures it will be seen that *the whole 7 per cent. is accounted for by infants under three months old—the three months of non-vaccination*, so that of course vaccination is not a factor in the case.

Such, in brief, is the argument from the Scotch statistics. Your issue of Dec. 1st last contained a letter from Dr. Creighton, occasioned by a valuable criticism in your columns of the previous week. In it Dr. Creighton said, "I showed also, by reference to the registration figures for Scotland, that most of the deaths from infantile syphilis happened in the first three months of infancy, whereas the statutory limit of vaccination in that country is six months. Dr. McVail used that argument, doubtless independently, in his book published two months after mine, and he has been duly commended in your own columns and elsewhere for establishing a fact so well calculated to meet the alarmist charges against vaccination. But the argument from the Scottish statistics was first established by myself."

Passing by the fact that I have not been commended, either duly or unduly, in your columns for establishing the point in question, I now turn to the reference given by Dr. Creighton, and find that on p. 153 of "Cow-pox and Vaccinal Syphilis," he says that "probably" it is the case that "a great part" of the increased syphilitic mortality under one year "will have to be looked for" elsewhere "before we go to vaccination as a last resort." Then he goes on: "This is made all the more likely by an examination of the more recent registration returns for Scotland, which give the mortality in separate columns for the first three months of life, the second three months, and the next six months; if these returns may be taken as showing forth the incidence upon the several quarters of the first year for England also, we should have the significant fact that considerably more than half the deaths from syphilis under the age of one belong to the first three months of infancy." He adds, however, that "that fact certainly does not make absolutely against the hypothesis of an increase being due to vaccinal infection." This is positively the only reference to Scotch statistics that Dr. Creighton's book contains, and on this slender basis he rests his claim to have "established the argument." The point is in itself a trifling one, but it is a valuable indication as to the amount of proof which Dr. Creighton thinks sufficient in forming a conclusion. He is of opinion that he has "established" a number of new points. He has proved, he believes, that the milkers' tradition of the anti-variolous power of cow-pox was "an old wife's fable,"[1] that the variolous test, as practised by the early vaccinators, was a sham, that cow-pox has its analogue not in small-pox but in syphilis, that vaccination is nothing but a "grotesque superstition," and that its author, Jenner, "went blundering into visionary nonsense in the first place, and at length into systematic mystification and chicane." Let any reader of Dr. Creighton's books, who has not the opportunity of consulting the evidence at first hand, recollect in regard to such assertions how little in the way of demonstration it takes to satisfy the doctor that he has "established" his argument.

Questions of priority in such matters are as a rule of merely personal interest, and in regard to that incidentally mentioned by Dr. Creighton, I will only remark that, as he courteously suggests, my reference to the Scotch argument was quite independent of his, though his book was published two months before mine. The necessary figures had been obtained by me from the English Registrar-General many months before, and indeed even after the manuscript was in the printer's hands, its publication was, owing mainly to illness, delayed for about half a year.

I am, Sirs, yours sincerely,

Aug. 5th, 1889. JOHN C. MCVAIL.

THE SANITARY ASPECT OF BOVINE TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—In connexion with the above subject, it has afforded me unfeigned pleasure—and I think I may say that it will have given equal pleasure to all veterinarians interested in the question—to observe that, according to an

[1] In a review of Dr. Creighton's writings on vaccination, of which the first part appears in the current number of the Edinburgh Medical Journal, I have discussed this question somewhat fully.

Digitized by Google

announcement at p. 220 of your last issue, the decision of Sheriff Principal Berry in the tuberculosis case recently tried at Glasgow has met with such marked acceptance at the hands of so important a body as the combination of Medical Officers of Health of the North-western and Yorkshire branches of the Society of Medical Officers. Coming so closely upon the combination which was escheloned in Glasgow, with the view of assisting the Association of Butchers in its object of perpetuating the pernicious system previously so largely in vogue in Glasgow of passing the carcasses of tuberculous cattle for human food, it is very refreshing. To me the spectacle of a phalanx of medical officers of health arrayed on the side of those who wished to perpetuate the sale of the flesh of animals that had suffered from "*the scourge of the human and animal race alike*" was truly melancholy; and there was, it seemed to me, a certain tinge of irony in the circumstance, seeing that, in addition to the fact that so long ago as 1872 this matter was exhaustively discussed at a meeting of the West of Scotland Veterinary Medical Association held at Glasgow, the subject was brought before the Sanitary Association of Scotland and the British Medical Association in the Western City so recently as last year. In whatever way the action of the medical officers of health just referred to may be interpreted, there can only be one interpretation of the action of the medical officers of health of the North-Western and Yorkshire Combination; and I promise (or I think I may safely do so) all such combinations or associations that in this matter they will have the energetic and earnest support of the veterinary associations throughout the kingdom. In your issue of the 3rd inst. I also notice a recommendation of the Streets Committee of the Darlington Corporation to the Council (of that town I presume) in connexion with the use of milk from tuberculous cows. Personally, I shall watch with more than ordinary interest the outcome of this recommendation, especially as, so far as I know, there is no law at present in existence which enables the Darlington or any other Corporation to deal with animals (found in byres) suffering from tuberculosis, or with the milk from such animals. I am, Sirs, your obedient servant,

Royal Veterinary Col. Edin., Aug. 6th, 1889. THOS. WALLEY.

PHTHISIS IN THE BRITISH ARMY.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of July 4th you noticed a statement of Dr. R. Schmidt of Munich, that the cases of phthisis in the English army were 11·8 and the deaths 6·2 per 1000, but you very properly observed he neither indicated the source of his information, nor the period it embraced, nor, I would add, the countries they occupied. In THE LANCET for July 27th you offer some comments on Dr. Schmidt's ratios, derived from Dr. Parkes's "Manual of Hygiene" (fourth edition), on the frequency of phthisis up to 1871, and add to these from recent Reports on the Health of the Army up to 1885. Dr. Parkes pointed out that the deaths from phthisis in the service did not show the full effect of the influences giving rise to that disease among soldiers, and that the mortality among those discharged on account of it had to be taken into consideration, but he made no estimate of the amount of this correction. In like manner, the numbers you have taken from the medical reports deal with the deaths in the service only, and do not include any of those among the invalids after leaving it.

In January, 1887, I read a paper at the Royal Statistical Society "On the Mortality among the Troops serving in the United Kingdom from Consumption," in which the deaths of invalids from this disease were included, and the reasons for their diminution in recent years fully gone into. It had been found that about half of those so discharged died within two years, and, as all of them had active pulmonary disease with considerable destruction of pulmonary tissue on leaving the service, the mortality among them would at least equal that in a similar number of persons in civil life in whom the disease was equally advanced; it was considered the early death of half their number would not deviate materially from the truth. In estimating the mortality from consumption due to military service, half the number discharged for this disease were therefore added to the deaths from it in the service, which gives a much closer approximation to the loss of life caused by the disease in the army than is generally adopted.

The following table taken from the paper in the Journal of the Royal Statistical Society (vol. l., p. 470), shows, in the first column, what the deaths from consumption among the troops would have been in the United Kingdom, with their peculiar age distribution, and at the rates observed among the male population of England and Wales at the corresponding ages. The second column shows the deaths which actually occurred in the service; the third gives the half of the discharges for phthisis; and the last the sums of these two, or the total deaths due to military service in the United Kingdom at each period. The total deaths have

Periods.	Phthisis in army at civil rates, per 1000.	Phthisis observed, per 1000.		
		Deaths.	Half of discharges.	Total deaths.
1837–46	5·09	8·53	0·85	9·38
1860–64	3·63	3·07	2·70	5·77
1865–69	3·81	2·57	2·26	4·83
1870–74	3·39	2·43	2·21	4·64
1875–79	3·21	2·45	2·22	4·67
1880–84	2·70	1·92	1·71	3·63

diminished nearly two-thirds of their amount from 1837–46 to 1880–84, but in every period they have considerably exceeded what would have occurred among the same body of men in civil life. It would occupy too much of your space to go into detailed explanations of these changes here, and I have accordingly to refer such of your readers as wish for further information on these points to the original paper.

The following statement of deaths per 1000 from phthisis in the different groups of foreign stations, including those of invalids from them on passage home, and until disposed

Stations.	1859–73.	1879–84.
Mediterranean	3·29	2·18
American	3·20	2·78
West Indian	3·42	2·14
Cape of Good Hope and Natal	3·09	1·35
Mauritius and Ceylon	3·80	3·20

of, and half the number of men discharged for it, for 1859–73 and 1879–84, shows there has been a manifest reduction of that disease abroad as well as at home.

I am, Sirs, your obedient servant,

ROBERT LAWSON.

London, Aug. 2nd, 1889. Inspector-General of Hospitals.

*** In our annotation of July 27th we gave the death-rate from phthisis *in* the service, not that caused *by* the service. Our remarks were made with reference to Dr. Schmidt's comparison of the number of cases and deaths in different armies. As there was nothing stated regarding the amount of invaliding for phthisis from each of these, we could not make the correction necessary to show the probable number of deaths among men after their removal from the effective strength on this account. Our remarks therefore applied only to the relative prevalence and mortality among soldiers while serving.—ED. L.

THE NOTIFICATION OF INFECTIOUS DISEASES BILL.

To the Editors of THE LANCET.

SIRS,—General practitioners throughout the country are greatly indebted to you for the able articles which you have rceently published on this subject, especially for that of July 20th, which has been of the greatest service. There cannot be a doubt that the majority of the profession are in favour of notification as a means of checking the spread of infectious diseases. Our objection is not to notification, but to the mode in which Mr. Ritchie's Bill seeks to have it carried out. We agree that it should be the duty of the householder or person in charge of the patient to notify, but we regard it as a departure from strict right, and also inexpedient, to require direct notification on the part of the medical

Digitized by Google

attendant, when the latter is called in at the discretion and expense of the householder. By throwing the duty on the medical man, the promoters of the Bill confess that they do not expect the householder to do his part; and, indeed, where the dual system is in force under local Acts, the householder's report is generally dispensed with, two accounts of the same case being only embarrassing to the authorities. Similarly, there have been about a score of prosecutions of medical men, but of householders barely a fourth of that number (I cannot recall more than three). Surely this is not the way in which to teach the people, that "England expects every man to do his duty." It would be far preferable to insist on notification by the person primarily liable, and not to let ignorance be any excuse, except from inability to obtain a medical certificate.

The party of private practitioners to which I belong is quite willing to be under compulsion to certify in a case of infectious disease just as we do to the cause of death and to vaccination. But we regard it as unprofessional and un-English to send the information to the authorities direct, except at the householder's request. It is repugnant to our nature to bring the healing balm in one hand and the hangman's rope in the other.

We are therefore persuaded that the dual system of notification is wrong in principle. It has also been proved to be worse than useless in practice; for, in the year 1887, when the death-rate from zymotic diseases was high throughout the country, and when consequently there was an excellent opportunity for showing the superiority of that system, it lamentably failed—so much so that the large towns under the dual system lost 206 per million more persons from *notifiable* diseases than died of the same diseases in the large towns under no system. The same thing holds when a series of years is taken: the dual system is worse than useless. And no wonder; for it leads the public to regard the doctor as their natural enemy, as one who will turn upon them for a paltry half-crown. Accordingly, they put off sending for him as long as they possibly can, and until the mischief is done which he could have prevented.

The single, or householder, system has no such ill effects, and in proof of this I can confidently appeal to the Registrar-General's returns for Bradford and Norwich.

If Mr. Ritchie will only transform his Bill so as to embody the single system of notification (as carried out in Bradford), instead of the dual system, and then make its acceptance unconditional throughout the country, we shall all be pleased. It will then be a good and strong measure (which it certainly is not at present), and he will find it perfectly efficient.—I am, Sirs, yours faithfully,

Kingston-on-Thames, Aug. 7th, 1889. D. BIDDLE.

TREATMENT OF HIP-JOINT DISEASE.

To the Editors of THE LANCET.

SIRS,—In his recent interesting lectures at the Royal College of Surgeons, Mr. Howard Marsh refers at some length to my experience on the question of hip disease. I should like to take the opportunity of thanking him for his kindly reference to me, and he will not, I am sure, take it amiss if I venture to point out certain, as I think, fallacies in his statistics, and in the conclusions he draws therefrom. I am the more anxious to do this because a similar mode of reasoning is being constantly brought forward by those who, lacking Mr. Marsh's moderation, seek to discredit all operations of the nature of excisions in the treatment of joint disease.

Mr. Marsh first refers to the results of treatment other than excision in the case of the hip-joint. He gives the results of 76 cases, of which 37 had abscesses and the rest had not suppurated. Mr. Marsh then analyses the results in these cases, comparing them with the results of excision, naturally to the disadvantage of the operation. But it is not, I think, unreasonable to say that the comparison is not valid, and that no such conclusion can be drawn from these figures. For in the first place more than half Mr. Marsh's cases were those of disease in which no suppuration had taken place—i.e., of early disease in which a good result would naturally be expected without operation. Secondly, the figures are taken from a comparatively small proportion (76 out of 160 written to) of those selected. To make out the case against operation, we ought to know what became of the 84 who did not appear. Is it not possible that death, or what one of my patients graphically called "permanent cripplehood," may have had something to do with the absence of the others? This would, of course, invalidate the conclusions altogether, since only the recoveries would come. My conclusions, on the other hand, were based on the results of the whole of the cases (except one) treated by a certain method.

Mr. Marsh next takes 614 cases treated since 1880 at the Alexandra Hip Hospital, with a mortality of 6 per cent., or including incurables, 8·4 per cent. These are compared with my cases of excision, with a mortality of 20 per cent. But is there not a clear fallacy here? Were Mr. Marsh's 614 all cases in which suppuration had occurred, or the disease was as far advanced as in my excision cases? If any of these 614 were cases of early slight disease, the comparison of course falls to the ground. To compare two different modes of treatment, must we not require that they be employed in similar cases?

Consideration for your space prevents my commenting upon much that is valuable and interesting in Mr. Marsh's lectures. Two points, however, I must ask you to allow me to mention. First, that I do not think that the evidence of the Alexandra Hip Hospital is conclusive on the subject of the frequency of necrosis. My own experience, and I think Mr. R. W. Parker would agree with me, is that I have frequently found necrosis, and I think I can give an explanation that is probable of the difference in our views. In the Alexandra Hospital patients are kept in for an indefinite time, and therefore are not under the unfavourable conditions of liability to frequent exacerbations of disease from periods of neglect that ordinary hospital patients are. Hence I can well imagine not only that Mr. Marsh's results are better than those of other hospital surgeons, but that he sees less of necrosis.

May I lastly point out that many writers on the subject of operation in joint disease (among whom I should not class Mr. Marsh) write as if those who advocate excision never employ any treatment short of operation? They do not seem to realise, what everyone surely admits, that the number of joints requiring operation is small compared with those that recover without, *provided suitable treatment can be carried out.* What those who condemn excision *in toto* require to make out their case is to produce a large series of consecutive cases of the same degree of disease in the same class of patient as those which have been published by operators, and to show a better result without operation. I am fully aware of the difficulty of compiling such a report accurately, but it is, I think, the only way in which a valid conclusion can be arrived at.

I am, Sirs, yours faithfully,

Manchester, July 30th, 1889. G. A. WRIGHT.

PROFESSIONAL TATTLE.

To the Editors of THE LANCET.

SIRS,—Your remarks in a leader in a recent issue of THE LANCET condemning certain articles which have appeared in non-medical public journals on the death-bed scenes and sayings of celebrated men were much needed and timely. What objects the writers of these articles have set before them it is not easy to discover. To themselves we scarcely think there can accrue either honour or profit, if we except the brief popularity they may obtain, and in the surviving relatives, whose sacred feelings they thus violate, they can only create pain and disgust. During a fairly long professional life I have seen many things to deplore in medical practice, but hitherto, wherever I have lived and whatever grade of professional life has presented itself to me, I have ever felt that the secrets of the time of sickness and its frailty and weaknesses were held inviolate by the family medical man. Of late, however, all is changed, and we seem to have become on these matters as garrulous as the Barber of Seville, and if this evil is not sternly and speedily checked amongst us, we must not wonder if the public should lose all confidence in us and all their wonted respect for us and our profession. I am personally gratified that you have taken up this important matter.

I remain, Sirs, yours obediently,

King's Lynn, Aug. 5th, 1889. WM. DALE, M.D. Lond., &c.

DR. DETTWEILER'S POCKET-FLASK FOR THE DISPOSAL OF THE SPUTA IN PHTHISIS.

To the Editors of THE LANCET.

SIRS,—Dr. Arthur Hill Hassall has given most sensible advice in his paper "On the Disposal of the Sputa in Phthisis," printed in THE LANCET of July 27th. He

Digitized by Google

justly dwells on the danger of infection arising from the dried sputa when inhaled as dust, and he shows that the practice of spitting on the floor of rooms, or on the pavement of streets, or into handkerchiefs, is very injudicious. Dr. Hassall recommends the introduction of spittoons into all the rooms where consumptive people dwell, and the regular disinfecting and removal of the contents. As, however, spittoons are not to be found in the streets and in railway carriages and other vehicles, I venture to direct attention to the suggestion of Dr. Dettweiler of Falkenstein, that every consumptive person should carry a small flask and always expectorate into it. He has constructed such a flask, which he calls "Taschenfläschchen für Hestunde"—"pocket-flask for coughers." Dr. Dettweiler read a paper on this subject in April last, at the meeting of the Congress for Clinical Medicine at Wiesbaden. There would probably be no difficulty in obtaining the flask through surgical instrument makers. The contents of this flask can easily be disinfected once or twice a day by a solution of perchloride of mercury or other disinfectant; one part of perchloride to 200 of water, when thoroughly rubbed up with the sputa would, I should think, render the sputa perfectly innocuous.

To many persons such a suggestion may seem a very small matter, but the hygienic importance is very great.

I am, Sirs, yours faithfully,

Grosvenor-street, W., Aug. 1st, 1889. HERMANN WEBER.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Cremation of Dogs.

A WISE REGULATION is now in force here, which gives a sense of public security with regard to stray dogs. It is this: Certain members of the police force are told off to dispose of ownerless dogs which may be found straying about the town. Armed with a lasso, they seize their unsuspecting victims and lead them off to the place of execution. The killing process is effected by a dose of prussic acid, and the bodies are cast into a furnace used for burning the refuse from the interception of the sewage. Numbers of mongrels and curs of low degree are thus got rid of, to the relief of timid pedestrians.

Alleged Bad Meat Prosecution.

In the endeavour to secure a conviction in this important direction it is necessary to be careful that the arrangements are complete from a legal point of view. A butcher was summoned for exposing for sale a quantity of meat alleged to be bad, the number of pieces being specified. The prosecution wished to amend the summons by adding to the list of pieces exposed eighteen calves' hearts. This was objected to, and the proposed method of dealing with the case was characterised as very slipshod. The summons was withdrawn, and the bench ordered the corporation to pay all the witnesses 2*s.* 6*d.* expenses, and the defendant's solicitor a guinea.

The Pains of Childbirth

are usually stated to be extreme in comparison with other pains, yet occasionally it would seem not to be a difficult process. A young single woman retired to an outhouse, and shortly afterwards a full-grown child weighing 8 lb. was heard crying in the midden. Unfortunately, it could not be rescued before it was suffocated. The mother did not appear to be much the worse for passing through an ordeal which at times tries the nerves of the strongest women. She now awaits her trial for infanticide.

Bank Holiday.

The desire for change and excitement of various kinds is associated with the mode of life in large towns, and yearly increases. The scenes at the railway-stations this year have been unprecedented, and crowds have been unable to gratify their pleasurable instincts by distant journeys out of town. The woes of excursionists have been depicted in the local press, and remarkable instances given of the endurance and long-suffering gone through in the pursuit of pleasure. The followers of Epicurus would have hesitated to accept the conditions imposed in many instances for the prospects afforded—prospects more often never realised, and the precursors of many an aching head and weary limbs for days following. How far this excitement tends to the well-being of the community it is not difficult to estimate; such an artificial struggle cannot tend to health, though it may lead to sacrifice of the better impulses which promote true enjoyment and real recreation.

Birmingham, Aug. 7th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle Royal Infirmary.

AT the quarterly meeting of the Newcastle Royal Infirmary, held last week, it was stated that the subscriptions from the working men during the quarter had been £1669, being an increase of £229. So that the experiment, if it may be so called, of admitting working men to the governorships has been a complete success, and might perhaps be followed with advantage elsewhere when similar institutions are languishing from want of funds, and complaining that the working classes do not take a more active part in their support.

Sunderland.

The annual report of the Sunderland Infirmary is a satisfactory one. The *employés* connected with the various industries of the town have subscribed to the amount of £3783, being an increase of nearly £1000 over their contributions of last year. The medical report again shows a considerable advance in the number of patients treated in the infirmary over last year, the number being 4833, an increase of 933. The number of in-patients was 1770, an increase of 63. There had also been an increase in the out-patients and surgical accidents. The infirmary is nursed by sisters from the Tottenham Training Institution at a very small cost; and it is recommended by the governors that a fund should be established to make some provision for such sisters as are unable to continue their beneficent work from sickness, old age, or any infirmity. This fund will be commenced by a deduction of £100 from the infirmary receipts for the year ending June, 1890. I hear that Mr. A. E. Harris, who has been medical officer of health in Sunderland for nearly eight years, is a candidate for the same office now vacant at Leeds. Mr. Harris is well known as a scientific and hard-working sanitarian in the north, and has the satisfaction of knowing that many suggestions of his as to the health of Sunderland, have been carried out during his office, to the immense improvement of the health of the town. I regret to hear that Mr. Mordey Douglas, a well known surgeon in Sunderland, has returned from a sojourn at the Canaries in very indifferent health.

Alnwick.

In reference to the high death-rate prevalent at Alnwick the Local Board have consulted Sir Robert Rawlinson, who is well acquainted with the town and its sewerage system. He makes some valuable suggestions to the board, but tells them very plainly that ventilation will not very much improve bad houses, and that to his knowledge there are many of this sort in Alnwick, some towards the Castle entrance—dens, frequently used by vagrants and tramps. "Mend these," he says, "by new labourers' dwellings."

Darlington.

There was a strange scare in Darlington last week, so prevalent that the Mayor in Council found it necessary to allude to and contradict it. It was reported that the town crier had gone round with his bell warning the people not to eat any vegetables. Several loads of vegetables were unsold in the market owing to this scare. The Mayor very properly said that there was more danger to health in abstaining from fresh and clean washed vegetables than from their use.

Whitby.

Much sympathy is felt with Dr. E. P. Mead, an old and respected practitioner in Whitby, who has had the misfortune to lose his son under very sad circumstances. Mr. Mead was one of the chief officers of a Newcastle steamer, and while on an outward voyage in mid ocean was seized with rheumatic fever, and during the temporary absence of his attendant he got out of bed, went on deck, and leaped into the sea. Mr. Mead was not seen again.

Morpeth.

On the invitation of Dr. M'Dowall, the resident medical officer of the Northumberland County Lunatic Asylum, a

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

EDINBURGH.

University Graduation Ceremonial.

THE annual medical graduation ceremonial took place on Aug. 1st in the United Presbyterian Synod Hall. Sir William Muir, principal and vice-chancellor of the University, presided, and was accompanied by most of the members of the Senatus Academicus. Only one honorary graduate was made this year—the Rev. Archibald Henry Sayce, M.A., of Oxford,—on whom the degree of Doctor of Divinity was conferred. The candidates accepted for the degree of Doctor of Medicine—fifty-nine in number—appear to have sent in exceptionally able theses, as no fewer than eight gained gold medals; seven others were deemed worthy of competing for the dissertation gold medals, and twenty others received commendation. At the same time the degree of M.B. and C.M. was conferred on 164 candidates, of whom eleven had passed the necessary examinations with first class honours, and eight had passed with second class honours. These honour lists are larger than usual, as, however, is the list as a whole. After the numerous prizes had been awarded, Professor Crum Brown addressed the budding practitioners, and gave them some good, sound practical advice. He was exceedingly well received by the graduates, whom he welcomed amongst the members of the university of a higher grade. He pointed out that all the changes through which they had passed were not so much in medicine as in themselves. Ways of thought at one time untrodden had been converted into intellectual highways; and forms of thought at one time unfamiliar had now become habitual. Advising them on many points, he drew special attention to the fact that no one so much as a doctor needed to have the *mentem sanam in corpore sano*, and no one ought to know better how to keep both body and mind in good order. He referred, however, not to pampering, but to neglect. They knew that it was best that they should have their meals at approximately regular intervals, and that they should sleep in bed at night for a time varying with different persons from six to eight hours. Medical men could not always secure that—the door bell and the dinner bell often ringing at the same time. They might be called in the middle of the night, and they must go. They must accustom themselves to get their meals and their sleep when they could. They might do much—they ought to do what was possible by arrangement and forethought to keep the unavoidable irregularity within reasonable limits. If the worst came to the worst they could take a sandwich in their pocket and sleep in a patient's house. By the neglect of such precautions many valuable lives had been cut short, and it was the best men who were most likely to forget themselves; they did not notice or think of their own health until it was too late. He further remarked that a man was unfit to practise their profession if he was not in the true sense a gentleman, and his professional training, even the post-practical and technical parts of it, tended to make him one. Some of them might call to mind very skilful and successful physicians whose manners were not exactly what they would have liked. They must take care in such cases not to judge of their neighbours from a purely society point of view. At the same time, he might remind them that they themselves should conform in all lawful matters to the usages of polite society. Their education, they must remember, had not yet come to an end; it must be continued as long as they lived, but it would henceforth be carried on under new conditions. They would now be directly and individually responsible for what they did. They would often have to make up their minds without help and without appeal. Their teachers and their examiners that day declared that, in their opinion, they as graduates were fit to undertake the solemn duty of relieving suffering humanity. He urged them not to set about their work with a light heart, but to remember that a very precious thing had been entrusted to their care.

The 2nd Division of the Volunteer Medical Staff Corps.

On Friday, Aug. 2nd, fifty all told of the 2nd Division V.M.S.C., under Surgeon Hepburn, left the Waverley station for London *en route* for Aldershot, where they are now encamped for a week's training along with the other divisions of the Volunteer Medical Staff Corps. The men were apparently highly delighted at the prospect of another camp sojourn, and everyone was in the best of spirits. Should the weather be at all favourable there can be little doubt that an enjoyable and profitable time will be spent. A number of admiring friends went down to the station to see the division set out.

Edinburgh, Aug. 6th.

GLASGOW.

Public Health.

For the fortnight ending July 27th there were 427 deaths registered, a death-rate of 21 per 1000 living, as against 24 in the previous fortnight. The epidemic of whooping-cough and measles is falling off, the combined death-rate from these two diseases being 1·8 per 1000 in place of 2·6. In both affections the mortality is the lowest since the first fortnight in January. Already 583 deaths from measles have been registered this year, which will be distinguished as the year of the severest epidemic of measles since 1871.

University Graduation Ceremony.

At the recent graduation ceremony Professor George Buchanan delivered an address which has given rise to not a little discussion and newspaper controversy. His first topic, the overcrowded state of the profession, must have been profoundly interesting to the ninety-one graduates who listened to him. He had very little comfort to give, however, save what could be expected from the statement that we have the same cry of overcrowding from all professions and businesses at present. He quoted statistics to show that the number of medical men a district will support was not to be measured by population alone. In Glasgow, in 1850, we had 255,000 people in the postal area, with 231 medical practitioners; at the present date we have 750,000 in the same area, with only 375 practitioners; and yet there is no place from which more complaints come as to superabundance of medical men. In discussing the needs of the University he deprecated the foundation of any more bursaries, but said that the great want was a larger number of fellowships, teaching fellowships, of from £150 to £200 a year. He discussed also the Universities Bill, the subjects of examinations and teaching, advocating a system of less lecturing and a freer use of text-books.

Medical Statistics.

Professor Buchanan's favourite anomaly, that we should have the feeling of professional overcrowding in Glasgow, when we have relatively far fewer medical practitioners than we had forty years ago, becomes less puzzling in the light of some statistics which have been published in connexion with the newspaper correspondence to which Dr. Buchanan's speech gave rise. It seems that there are 40 medical institutions connected with the city, including 2 large infirmaries and a third in course of erection, 3 parochial hospitals, 4 asylums, 3 fever hospitals, 9 special hospitals, 6 convalescent homes, 2 homes for incurables, 2 nursing institutions, 4 general dispensaries, and 5 special dispensaries. There are also out-door departments connected with all the large infirmaries, 2 of the parochial hospitals, 8 of the special hospitals, and 1 of the nursing institutions. Only one of these institutions, the Royal Infirmary, was in existence before the end of last century, 6 were established in the first half of the present century, 9 were started between 1850 and 1870, and 21 have arisen since the latter year. The number of medical officers attached to these 40 institutions amounts to 258; 125 of these are paid, 45 are resident. Some medical officers hold more than one appointment; 36 men connected with 4 of the principal institutions hold 82 appointments. In the 40 institutions we have 5171 beds; average number occupied, 3519. If the population of Glasgow (including "Greater" Glasgow) be taken as 750,000, we have one bed for every 145 people. The number of in-door patients during the past year in these 40 establishments was 31,603, equal to 1 in 23 of the population; out-door patients, 97,144, or 1 in every 8 people; total, 128,747, or 1 in rather less than every 6 of the population. These refer to separate patients; the number of consultations or attendances reaches 350,950.

Digitized by Google

There are upwards of 370 medical practitioners in Glasgow and neighbourhood. With regard to medical students, there were 784 enrolled last year at the University; 53 enrolled in medicine and arts; total, 837. During the same period there were 119 at Anderson's College Medical School, and about a similar number at the Royal Infirmary School. This gives a total of over 1000 students at our medical schools.

Glasgow, Aug. 6th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

DUBLIN.

Royal University of Ireland.

THE number of candidates who entered for the several examinations, which were concluded July 23rd, amounted to 1867, but the actual number who presented themselves for examination was 1751. Of these, 29 retired before the close of the examination, 644 were rejected, and 1078 passed, the number of passes being a little over 61 per cent., and of rejections a trifle over 36 per cent. The receipts of the University for the year ending March 31st last, including last year's balance of £10,691, amounted to £33,891, and the expenditure to £24,976. The general expenditure for examinations amounted to £11,854, as against £11,819 for the preceding year. During the year the sum of £1326 was spent on the equipment of the laboratories. J. Johnstone Shaw and Edward Cuming have been elected representatives on the Senate, in place of the Rev. Dr. Porter, deceased, and of Mr. Shaw, whose term of office had expired. There were three candidates for the two vacancies.

Royal Barracks, Dublin.

Although the number of typhoid fever cases which occurred in these barracks was considerable, yet the deaths were comparatively few, being not more than six. The Royal Lancaster Regiment, which recently occupied the barracks, will encamp under canvas during August and September in the Phœnix Park, and the Palatine-square and the Richmond Barracks will during that time undergo a thorough overhauling. The Royal Square (the most insanitary portion of the Royal Barracks) will be used as ordnance stores), and when the new cavalry barracks are finished the cavalry square will be occupied by the Army Service Corps. Only one battalion of infantry will in the future be quartered in the Royal Barracks, and that will be in the Palatine-square, the battalion which occupied the Royal Square being located in the Wellington Barracks.

Queen's College, Galway.

As an explanation of the comparatively small number of students who attended this college for the past session, it is well to bear in mind that the institution is situated in the poorest and most backward part of Ireland, at a distance from other centres of education. It follows from this that its function is to awaken and foster a desire for higher education, rather than to supply a pressing demand, and it is gratifying to learn that the college can justly claim to have given an impulse to educational progress, and to have conferred substantial benefits on the youth of a remote province. During the session 1888-89 there were 107 students on the books of the college, of whom forty-two were in the Faculty of Medicine. The rapid development of medical science, especially in the department of biology, has called for an enlargement and improvement of scientific apparatus, so as to keep pace with the progress of discovery. The department of physiology affords a remarkable instance of the method of teaching the natural sciences that has been introduced in recent years. Until recently instruction in physiology consisted in a course of lectures illustrated by experiments performed by the lecturers and by histological specimens shown to the students. Now, however, in addition to attendance on lectures, the student must himself make the various analyses, preparations, and experiments that were previously only shown to him. Important additions have been made to the museum of natural history, which may now be said to be in a state of perfect efficiency for teaching purposes, while the chemical laboratory also affords ample accommodation for students.

Health of Dublin for June Quarter.

The births numbered 2540, and the deaths 2082, the latter being equal to 23·6 per 1000 as compared with 28·7, the average for the second quarter of the past ten years. Zymotic diseases caused only 202 deaths, being 136 under the average number for the June quarter of the last ten years. Measles caused 37 deaths, scarlatina 5, typhus 5, whooping-cough 30, and erysipelas 2. No death from small-pox has been registered in the Dublin Registration District since the week ending March 3rd, 1888, and in hospital there has not been a case of the disease since July of last year.

Mr. Thomas Collins has been re-elected a representative on the General Medical Council for the Apothecaries' Hall for the ensuing year.

Mr. P. J. Finegan has been elected medical officer to Carlingford Dispensary, Dundalk Union.

Dublin, Aug. 6th.

BELFAST.

Fatal Sewer Accident in Belfast.

On June 29th four *employés* of the Belfast Town Council descended one of the main sewers for the purpose of having it cleaned, when they were partially suffocated, and were with difficulty rescued and taken to the Royal Hospital. One died soon after admission, apparently as much from submersion as from sewer gas; a second died in a day from acute pneumonia; the other two recovered. A very full inquiry was made into the circumstances, and Dr. Letts, Professor of Chemistry in Queen's College, Belfast, who was retained by the Town Council to investigate the matter, has just presented his report, which is very thorough and exhaustive. Dr. Letts' conclusions are: 1. The air ordinarily in the sewer, even with closed ventilators, was never bad enough to cause any sudden accident. 2. When the man-holes are opened the sewer is rapidly and thoroughly ventilated. 3. On the day of the accident ample time was given for proper ventilation. 4. The accident was primarily caused by a sudden outburst of foul gas through a disused privy-pipe opening into the top of the sewer at a distance of six feet from the place where the accident occurred. In investigating the matter, Dr. Letts had the sewer opened from the outside. A short distance beyond where the accident occurred a brick structure was encountered on the roof of the sewer. When this was opened a curious smell was at once detected of a tarry odour, and on Dr. Letts applying a light, a pale blue flame shot out and then retreated downwards, burning for perhaps a minute. This air contained a great deal of marsh gas. Further excavation showed that a nine-inch earthenware pipe branched off from the brick shaft, which had a circular hole in the bottom opening into the sewer. In this earthenware pipe was a quantity of mud, apparently old soil from a closet or privy. The upper end of the earthenware pipe was found plugged. Letheby's experiments have shown that London sewage, when shut in a vessel not exposed to the air, gives off gas rapidly. He found this consisted of marsh gas, CO_2, N, and H_2S. Dr. Letts believes the gas he found was similar, but had more CO_2. Dr. Letts thinks the tube containing the soil, which was disengaging the gas, may have got choked for a time, and consequently a considerable volume of gas may have been imprisoned beyond the obstruction. After a time, in the hot June weather, this would cause so much pressure as to force the obstruction and to issue in a gust into the sewer. The two men in the sewer, in the neighbourhood of the pipe, are prostrated from the effects of the gas; they fall in the water; a panic arises as the men recover from the effects of the gas; some endeavour to pass one way, some another, to escape, and there can be little doubt that the men who are dead lost their lives not through gas poisoning, but by submersion in the sewage matter and its subsequent effect on the lungs. 5. The noxious constituent of the gas was probably CO_2, which prostrated the men in the sewage water. 6. All the men seriously affected or killed by the accident either swallowed sewage matter or it got into their lungs. 7. It is probable that none of the men would have been injured but for the dips in the sewers and the consequent accummulation of sewage water. As a result of his very careful examination, Professor Letts recommends for the prevention of accidents in the future: 1. A reconstruction of that part of the sewer where the accident occurred. 2. The sewers should not be cleaned except in dry weather, nor should men be sent into them then. 3. Before cleaning any sewer two men at least should walk the whole distance, each provided with a lamp, and then return and report to the ganger. 4. When cleaning a sewer the men should have two lamps alight

Digitized by Google

with them. 5. The men should be directed to search for openings in the sewers, and to report immediately if any sewer is in a bad condition, either as regards depth of water, foulness of air, or defects in brickwork.

Queen's College, Belfast: The President's Report.

From the report of the President (Dr. Hamilton), just printed, I learn that the total number of students attending the College during the session 1888–89 was: in arts, 174; in medicine, 222; in law, 22; in engineering, 11. As seven students attended in more than one faculty, the entire number in attendance was 422. The average number of students in attendance during each session of the first ten years of the history of the College was 189·1; during each session of the second decade, 368·2; in the third, 400·3; in the fourth decade now ended it is found to have risen to 473·4. During the forty years of its existence, 4681 students altogether have entered the College. At the examinations of the Royal University, held during the last academic year, 393 students of the Belfast College passed in the various grades. Of these 20 passed the first University examination in medicine, 30 the second, 47 the third, and 30 medical degrees were obtained. After giving details of the successes of Queen's College students at other universities, a special tribute is paid to the memory of Dr. Porter, the late President, whose death in March last was such a serious blow to the cause of education in the north of Ireland. The report concludes by calling attention to the great want of an additional grant of money for providing increased accommodation in the chemical and biological laboratories. The required sum would be about £8000.

Presentation of a Park to Belfast.

On Aug. 1st a letter was read at the monthly meeting of the Town Council from Mr. R. G. Dunville, D.L., offering to present to the city, free, a piece of ground containing five or six acres of land, worth, it is said, £7000, for a public park. The ground is situated in a district which is rapidly increasing in population. A hearty vote of thanks was passed to Mr. Dunville for his generous gift.

Hospital Saturday.

Notwithstanding that Hospital Saturday (Aug. 3rd) was anything but a favourable day, the morning being very wet, a larger sum was realised than in either of the two previous years. The total amount raised was about £300. This includes, however, £38 contributed by the members of the Queen's College Musical Society, as the result of an afternoon performance of "Maritana," given by them in the Theatre Royal on Saturday in aid of the funds of the hospital.

Hydrophobia.

On March 14th a man, while walking along College-square, one of the leading thoroughfares of Belfast, was bitten by a dog snapping at his hand. The wound, which was at the root of the thumb, healed in ten days, and nothing further developed until July 28th, when he was taken ill, and Dr. N. J. McDonnell pronounced the disease to be hydrophobia. He was brought to the Royal Hospital the next day (July 29th), when it was noticed that he had difficulty in swallowing fluids, convulsive attacks, and pain and loss of power in the right arm. On the third day after admission he became delirious and violent, and this continued until 2 A.M. on Friday, Aug. 2nd, when he died. Pneumonia set in previously to death. After hearing the medical evidence at the inquest, the jury returned a verdict that he died from hydrophobia.

Belfast, Aug. 6th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Cases of Poisoning at Hyères and Havre.

PROFESSOR BROUARDEL read his report at the Academy of Medicine, giving the result of his investigations on the cases of the wholesale poisoning that took place a few months ago at Hyères and at Havre. He observed that between the most acute forms of poisoning, those in which death takes place in a few hours and those which determine accidents the evolution of which is accomplished in some weeks and even months, there is a great analogy with the cases of poisoning at Hyères, where, it will be remembered, the medical men at first supposed that it was an epidemic of enteric fever, then they thought it was an epidemic of influenza, finally an epidemic recalling acrodynia, but when symptoms of paralysis showed themselves, all hypotheses disappeared, and the truth was discovered. According to Dr. Brouardel there are four distinct periods in arsenical poisoning: the first is marked by digestive troubles, the second presents eruptions and a laryngo-bronchial catarrh, the third is characterised by sensory troubles, and the fourth period by paralysis; but until this becomes manifest, one may be led to believe that he has to do with some gastric disorder, influenza, or with acrodynia. But the most remarkable part of Dr. Brouardel's communication was the discovery of arsenic in the osseous tissue, while there was no trace of this substance in the viscera where it is habitually found. M. Pouchet, who took up the chemical part of the researches with Dr. Brouardel, observed that arsenic may be found not only in the principal viscera, the skin, and the hair, but also in the bones, and principally in the spongy tissue, where it is to be found even when no trace is left in the viscera. Dr. Brouardel then indicated the means by which poisoning by arsenic may be discovered. He said that the linen which may be soiled by the dejections should be secured; the urine, which should be drawn off by the medical man himself, should be analysed; and search should be made in the hair for arsenic.

Heredity of Myopia.

Dr. Motais of Angers read a note on the Heredity of Myopia. The author had examined the families of 330 young myopic subjects, and arrived at the following conclusions: 1. The hereditary influence of myopia is manifest. 2. It exists in 216 out of 330 families. 3. Hereditary myopia is characterised by its early appearance, its comparatively rapid development, and the high average of its degree. 4. Myopia is transmitted by the father to the daughter 86 times out of 100, and by the mother to the son 79 times out of 100. Heredity is crossed.

Spectacles and Eye-glasses.

Dr. G. J. Bull, M.D., of the Faculty of McGill's University (Montreal), has lately taken his degree in Paris, and chose for the subject of his inaugural thesis, "Spectacles and Eye-glasses." After having practised about twenty years in America, the greater part of which time Dr. Bull practised ophthalmology in New York, he came over to Paris, and perfected himself in this branch under the guidance of Dr. Javal, the celebrated ophthalmologist, with whom he worked at the laboratory of the Sorbonne. Those who wish to learn how to wear spectacles and eye-glasses should read Dr. Bull's newly published work, which is the reproduction of his thesis, containing, in addition, an introduction by Dr. Javal. The work is most interesting, and of great theoretical and practical value, particularly to those affected with astigmatism. According to the author, for some years a more precise knowledge of astigmatism has produced a complete revolution in the science of ophthalmology. He says it is important to draw the attention of the public to the existence of this optical defect, which is more frequent than myopia and than presbyopia, and which is corrected by means of special glasses, cut to measure, after the indications of the oculist. As regards myopia, Dr. Bull states that infants are not born myopes; with very rare exception they become so with age, and more frequently because they acquire the habit of reading and writing at too short a distance. The eye, therefore, becomes developed in a defective manner. It is often said that myopia and presbyopia are two affections opposed and incompatible; but the author affirms that this is not the case, the real state opposed to myopia being hypermetropia. Dr. Bull is the inventor of a new optometer, a full description of which will be found in his work, where other useful hints are given for the preservation of the eyesight.

Tuberculosis.

The second Congress for the Study of Tuberculosis will be held at the end of the month of July, 1890, under the presidency of Professor Villemin, when the following questions will be submitted for discussion: — 1. The identity of tuberculosis in man and that of the bovines, gallinaceæ, and other animals. 2. The bacterian and morbid associations of tuberculosis. 3. The hospitalisation of tuberculous subjects. 4. Agents capable of destroying the bacillus of Koch, non-injurious to the organism, as regards the prophylaxy and the therapeutics of human and

Digitized by Google

animal tuberculosis. Intimation of intention to be present and subscriptions (20 francs) should be forwarded to M. G. Masson, Treasurer, 120, Boulevard Saint Germain, and that communications which concern papers should be addressed to Dr. L. H. Petit, General Secretary, 11, Rue Monge, Paris.

Death of M. Armand Hayem.

A case of suicide, under most painful circumstances, occurred on Saturday last, in the person of M. Armand Hayem, brother of our esteemed *confrère* Professor Hayem. The deceased gentleman had only recently been elected a member of the Academy of Sciences. He had been for some time labouring under great mental depression, which was accompanied by symptoms of dyspepsia, for which he was treated by some of the leading members of the faculty. He, however, fell into a melancholic condition, and being, as he said, afraid of dying of inanition, he put an end to his life by shooting himself, the bullet passing through his right temple.

Dr. Sydney Ringer of London has been elected Corresponding Member of the Academy of Medicine.

Paris, Aug. 6th.

THE SERVICES.

ARMY MEDICAL STAFF.—The Commission of Honorary Brigade Surgeon Benjamin Lane as Assistant Surgeon is antedated to May 8th, 1852, such antedate not to carry back pay or allowances prior to June 5th, 1882; Sergeant-Major David James Gillman, Medical Staff Corps, to be Quartermaster, with the honorary rank of Lieutenant, vice Honorary Lieutenant W. Murray, retired (dated Aug. 7th, 1889).

VOLUNTEER CORPS.—*Artillery:* 3rd Volunteer (Kent) Brigade, Cinque Ports Division, Royal Artillery: The undermentioned Acting Surgeons to be Surgeons: C. Arrol (dated Aug. 3rd, 1889); R. J. Bryden (dated Aug. 3rd, 1889). 1st Midlothian: Surgeon P. A. Young, M.D., to be Surgeon-Major, ranking as Major (dated Aug. 3rd, 1889).—*Rifle:* 2nd Volunteer Battalion, the Queen's Own (Royal West Kent Regiment): Acting Surgeon D. T. Playfair to be Surgeon (dated Aug. 3rd, 1889).—2nd Volunteer Battalion, the Prince of Wales's (North Staffordshire Regiment): Surgeon W. G. Lowe, M.D., to be Surgeon-Major, ranking as Major (dated Aug. 3rd, 1889).

Obituary.

CHARLES SAMUEL WEBBER, F.R.C.S.

AMONGST the many men in our profession full of quiet and unobtrusive goodness and kindness, few, if any, have possessed these qualities in a higher degree than did Charles Samuel Webber, who died on the 20th ult. Of late years, owing to a very painful affection, he had been compelled to retire absolutely into private life, and he was therefore known but little to the medical men of the present day; but those who did know and see him found him, in the midst of his sufferings, always full of patience and kindness, desirous to work for others as far as his strength allowed, and always intelligently interested in all that concerned his profession. He was born at Hopton, Suffolk, on Aug. 7th, 1809, and was the only son of Samuel Webber, surgeon, of that place, who was Colonel Commandant of the Blackwater Regiment of Volunteers, and deceased in 1822. Mr. Webber entered at Guy's and St. Thomas's Hospitals and subsequently studied in Paris. He joined the Society of Apothecaries as long ago as 1831, and became M.R.C.S. in 1836, and a Fellow of the College in 1864. In the earlier part of his career he assisted Mr. Samuel Randall of Orford, Suffolk, but subsequently obtained an appointment, then much sought after — namely, that of Surgeon-Superintendent under H.M. Colonial Lands and Emigration Commission. It is almost needless to say that he was a great favourite and very popular with the emigrants; and that he well utilised his time is proved by the fact that the results of his experience were published under the title of "A Journal of a Surgeon Superintendent" by the Commissioners. He had previously published in THE LANCET an interesting and instructive "Case of Strangulated Hernia successfully treated by the Exhausting Syringe attached to an O'Beirne's Rectal Tube." He was a member, and formerly Vice-President, of the Harveian Society.

In 1849 Mr. Webber married Elizabeth, daughter of Mr. M. J. Raynes, of Norwich, and he at that time resided in Connaught-square. Some years afterwards he took into partnership Dr. John Easton, and, in doing so, the scrupulous and punctilious honour and truthfulness which pervaded his character were conspicuously shown, for in the negotiations which took place he was especially careful to under-state and to under-estimate the value of his practice rather than to exaggerate its worth; and, as a matter of fact, the result of the first year's partnership proved that the assets were very notably beyond the amount at which Mr. Webber had stated them. Thus he partially retired from practice, and after a while felt obliged, owing to the state of his health, to altogether relinquish it; and he subsequently changed his residence to 23, Abbey-road, N.W., where he died. His long malady, dating so far back as almost twenty years, was a very peculiar one, and greatly exercised the diagnostic skill of many of his medical brethren. His friend and neighbour, Dr. Richard Neale, with his son, Dr. William Henry Neale, were always ready to assist him in any and every difficulty, and he was not unfrequently seen by Dr. Hare, who alike valued the friendship of the patient and felt a deep interest in the case. He suffered from severe pain, which always appeared to have its centre at the left nipple line, about two inches below the costal cartilages, and from thence it seemed to pervade almost the whole of the left upper abdomen. The pains were almost always worst in the forenoon, and gradually got better after the bowels had been relieved, so that he was comparatively easy in the latter part of the day; but the regulation of his bowels was a matter of great difficulty, and he was obliged almost always to have recourse to enemata. Though he was a very uncomplaining man and possessed of much endurance, the pain—always more or less of the same character and in about the same position—was so severe that he was obliged to have recourse to opium and ultimately took very considerable doses of it. But this great remedy made his life endurable and at times comparatively comfortable, so that he was able in the latter part of most days to occupy himself in some useful (often charitable) work; and it without doubt prolonged his life by some years. The most rational diagnosis, and that which best covered and explained his many symptoms, was that he had some constriction—possibly from a former ulcer, but certainly non-malignant—of the large intestine some distance above the sigmoid flexure, and one very able medical man even advised that colotomy should be performed. Repeated and very careful examinations of the abdomen always failed to find any mass or tumour or, indeed, anything abnormal in the region of the pain, so that the physical signs were of an absolutely negative character. A post-mortem examination of the abdomen was made, and the writer is assured that nothing whatever was found in the intestines or elsewhere to explain physically those many years of terrible suffering.

But though Mr. Webber was compelled by his health to retire early from practice, he by no mean retired, so long as moderate strength remained to him, from work. He especially devoted himself to that remarkable medical charity, the British Medical Benevolent Fund, which, doing an immense amount of good, is conducted with such a minimum of expense that it may be considered in this respect a model to all the charities of the country. It ought to receive the support of every medical man in the country who can afford to give anything to charities; and it ought also to be supported by many outside the profession, as some mark of their gratitude towards those who, devoting themselves to the welfare of others, are often so ill-remunerated that they cannot lay up in store for their families or even for themselves if they attain old age. Mr. Webber was Honorary Financial Secretary to the Fund for several years up to 1877. The offices are entirely honorary, and it had been found that attention to the cases and to the money management of the Fund involved such an immense amount of work and time that no medical man ought to be asked to take the whole on his shoulders. The work was therefore divided, and Mr. Webber undertook the duties of "Financial Secretary." By his business habits, his thought and his hard work (notwithstanding that this was often done in the midst of much pain), it is not too much to say that he revolutionised, and yet wonderfully simplified, the mode of

Digitized by Google

keeping the accounts of the Fund, and so perfect was the plan which he inaugurated that it has been continued by his successors, with scarcely an alteration, down to this day. And so his influence in this and in many other ways remains, while he has passed away—loved, honoured, and regretted. "He being dead yet speaketh."—C. J. H.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the necessary examinations, were at the ordinary meeting of the Council on the 1st inst. admitted Members of the College:—

*Aaron, David Jacob, L.R.C.P.Lond., King's College Hospital.
Aylward, Walter Charles, L.R.C.P.Lond., 76, Fore-street, Ipswich.
Barber, Sidney Frederick, L.R.C.P.Lond., Sheffield.
Barkworth, Henry Smith, L.R.C.P.Lond., Balham.
*Basu, Bámun Dás, L.S.A., Trinity-square, S.E.
Beauchamp, Sydney, L.R.C.P.Lond., Battersea.
Bennett, Christopher H. Wentworth, L.R.C.P.Lond., Nantwich.
Bennett, Colin Edward Wilmot, L.R.C.P.Lond., Plymouth.
Berryman, Henry A., L.R.C.P.Lond., Fairholme-rd., West Kensington.
*Best, William Jenner, L.S.A., Louth.
Bishop, Reginald W. Snowden, L.R.C.P.Lond., Porchester-gardens, W.
Bokenham, Thomas Jessopp, L.R.C.P.Lond., Cheshunt.
*Bowlby, George Herbert, L.R.C.P.Lond., Torrington-square.
Bowman, Henry Moore, L.R.C.P.Lond., New Southgate.
Brown, David L.R.C.P.Lond., Stoke Newington.
Carpenter, Edgar Godfrey, L.R.C.P.Lond., Chiswick.
Challis, Henry Thornton, L.R.C.P.Lond., Hackney.
Charles, William Henry, L.R.C.P.Lond., Merthyr Tydvil.
*Clarke, John Kempe, L.R.C.P.Lond., Cardiff.
Clarke, John Tertius, L.R.C.P.Lond., Richmond-terrace, S.W.
*Clarke, Thomas Henry, L.S.A., Poplar.
Clemson, Thomas Fletcher, L.R.C.P.Lond., Botton-le-Moors.
Colyer, James Frank, L.R.C.P.Lond., Dulwich.
*Cooper-Pattin, William Harry, L.R.C.P.Lond., Cambridge.
*Coryn, Herbert Alfred William, L.S.A., Brixton.
Creswell, John Edwards, L.R.C.P.Lond., Douro-place, W.
*Crompton, Ernest, L.R.C.P.Lond., Exeter.
Crook, Arthur, L.R.C.P.Lond., Arbour-square, E.
Crosse, Reginald Edward, L.R.C.P.Lond., Norwich.
Crump, Thomas Greenwood, L.R.C.P.Lond., Kidderminster.
Curwen, Eliot, L.R.C.P.Lond., Hampstead.
Dallas, Stuart Alex. Charles, L.R.C.P.Lond., St. James-street, W.C.
Daniel, Herbert, L.R.C.P.Lond., Wymondham.
*Dawson, Ernest, L.R.C.P.Lond., Hampstead.
De Jersey, Walter Brock, L.R.C.P.Lond., Lambeth Palace-road, S.E.
*Dennison, Tom Stephenson, L.R.C.P.Lond., Hull.
Dodwell, Philip Rashleigh, L.R.C.P.Lond., Stanhope-street.
Eaves, Wilberforce Vaughan, L.R.C.P.Lond., Hornsey.
Farington, John, L.R.C.P.Lond., Manchester.
*Farquharson, George Sinclair, L.S.A., Canonbury.
Fazan, Charles Herbert, L.R.C.P.Lond., St. Helen's-gardens, W.
Fitz-Gerald, Edward Desmond, L.R.C.P.Lond.
Folker, Herbert Henry, L.R.C.P.Lond., Hanley.
Forward, Francis Edward, L.R.C.P.Lond., Chard.
Foster, Alfred, L.R.C.P.Lond., Delamere-street, W.
Frossard, Emilien Edward, L.R.C.P.Lond., St. John's, S.E.
*Gilchrist, Alexander William, Middlesex Hospital.
Gravely, Ronald Thomas, L.R.C.P.Lond., Cowfold, Sussex.
Griffith, John, L.R.C.P.Lond., Acton.
Habbijam, Ernest Thomas, L.R.C.P.Lond., Uxbridge-road, W.
*Hale, Edward, L.R.C.P.Lond., Liverpool.
Hall, Walter, L.R.C.P.Lond., Southampton.
Hamilton, Henry, L.R.C.P.Lond., Church End, Finchley.
*Harrison, James Herbert Hugh, L.R.C.P.Lond., Univ. Coll. Hospital.
Haslett, William John, L.R.C.P.Lond., Donegal
*Heberden, William Stanley, L.R.C.P.Lond., Weybridge.
Henniker, John Granville, L.R.C.P.Lond., Albert-gate Mansion.
Hicks, Edward James, L.R.C.P.Lond., Amhurst-road, N.E.
Hill, Leonard Erskine, L.R.C.P.Lond., Hampstead.
Hinds, Thomas Walter, L.R.C.P.Lond., Goudhurst.
Hitchon, Henry Hardacre Irving, L.R.C.P.Lond., Heywood.
*Holman, Henry James, L.R.C.P.Lond., North Dulwich.
*Holmes, James Willie, L.R.C.P.Lond., Sheffield.
Horden, Herbert Henry, L.R.C.P.Lond., University College Hospital.
Hore, Ernest Wickham, L.R.C.P.Lond., University College Hospital.
*Howse, Arthur Edward, L.S.A., Kingswood-rd., Clapham-park.
*Hunt, Arthur Henry Wm., L.R.C.P.Lond., Westminster Hospital.
Hutchinson, Roger Jackson, L.R.C.P.Lond., Cavendish-square, W.
Jackson, Basil Fred. F., L.R.C.P.Lond., Cornwall-road, Brixton.
Jacobsen, Geo. Oscar, L.R.C.P.Lond., Gordon-street, W.C.
*Jessop, John William, L.R.C.P.Lond., Crediton.
Johnson, Henry Percival, L.R.C.P.Lond., Sloane-street.
Johnstone, John Lloyd, L.R.C.P.Lond., Orreh, Wigan.
Jones, Arthur Wentworth, L.R.C.P.Lond., Bicester.
Jordan, Henry Martyn, L.R.C.P.Lond., Trinity-square, S.E.
Kent, Chas. Arthur, L.R.C.P.Lond., Craven-hill-gardens, W.
*Kent, Robert Thomas, L.R.C.P.Lond., Mornington-crescent, N.W.
Kerr, Geo. Douglas, L.R.C.P.Lond., Weeck-road, West Hampstead.
Lambert, Thomas Wilson, L.R.C.P.Lond., Lambeth-palace-road.
Lange, André Philip, L.R.C.P.Lond., Claverton-street, S.W.
Lea, Arnold Wm. Warrington, L.R.C.P.Lond., Sandbach.
Lemon, Edward Henry, L.R.C.P.Lond., Anerley.
*Light, Edwin Mellor, L.R.C.P.Lond., Lambeth-palace-road.
Lloyd, John Wesley, L.R.C.P.Lond., Liverpool.
Lodwidge, William Charrott, L.R.C.P.Lond., Basingstoke.

* Candidates who have not presented themselves under the regulations of the Examining Board.

Long, Edward Chas., L.R.C.P.Lond., Dewetsdorp, Orange Free State.
Mack, Cyril Gordon, L.R.C.P.Lond., St. Paul's-road, Canonbury.
*Masser, Edward Charles, L.S.A., Oakengates.
Morgan, Samuel Wolfastan, L.R.C.P.Lond., Clifton.
Munday, Richard Cleveland, L.R.C.P.Lond., Plymouth.
*Murray, George, L.R.C.P.Lond., Green-street, W.
Oakeshott, Walter Field, L.R.C.P.Lond., Highgate.
Offord, James Albert, L.R.C.P.Lond., Norwich.
Oldham, George Frederick, L.R.C.P.Lond., Dalston.
*Osborne, Frank, L.S.A., Bath.
Osburn, Harold Burgess, L.R.C.P.Lond., Clapham.
Parham, Hetman Charles Harris, L.R.C.P.Lond., Streatham.
Paton, Edward Percy, L.R.C.P.Lond., Highbury Quadrant, N.
Pearce, Frederick William, L.R.C.P.Lond., Canonbury.
*Plummer, Richard Henry, M.D. California, Gower-street, W.C.
*Ramsden, Herbert, L.R.C.P.Lond., Saddleworth.
Robinson, Edward Herbert, L.R.C.P.Lond., Salford.
*Russell, William Alfred, L.R.C.P.Lond., Aldersgate-street, E.C.
Saul, Victor Salmon, L.R.C.P.Lond., Hampstead.
*Scott, Sack Noy, L.R.C.P.Lond., St. Austell.
*Seccombe, Samuel Hubert, L.S.A., Whitechapel-road, E.
Sellers, Arthur Edward, L.R.C.P.Lond., Dalton, Huddersfield.
*Shadwell, Henry Eugene, L.R.C.P.Edin., Putney.
Sharpin, Archdale Lloyd, L.R.C.P.Lond., Bedford.
Smith, Richard Arthur, L.R.C.P.Lond., South Hampstead.
Spratly, Ernest Richard Woody, L.R.C.P.Lond., Rock Ferry.
Stocken, Leslie Maury, L.R.C.P.Lond., Ealing.
Stocker, Walter W., L.R.C.P.Lond., St. James's-square, Notting-hill.
Swallow, Allan James, L.R.C.P.Lond., Clapham-road.
Swift, Sidney Sampson, L.R.C.P.Lond., Liverpool.
Sykes, John Herbert, L.R.C.P.Lond., Southport.
*Talent, John William, M.B.Edin., Dist. Infirm., Ashton-under-Lyne.
Tibbles, William, L.R.C.P.Edin., Radford-road, Nottingham.
*Verano, Louis Lawrence, L.S.A., Torrington-square.
Vise, Arthur Blithe, L.R.C.P.Lond., Holbeach.
*Wakeham, Charles Henry, L.R.C.P.Lond., Hackney.
Walker, George, L.R.C.P.Lond., Lordship-lane, S.E.
Wallace, Richard Teale, L.R.C.P.Lond., Stamford-hill.
*Ware, Ernest Edwin, L.R.C.P.Lond., Lambeth-palace-road.
Wickham, Gilbert Henry, L.R.C.P.Lond., Lambeth-palace-road.
Wilkinson, James Howard, L.R.C.P.Lond., Dudley.
*Winn, Thomas Cromwell, L.S.A., Well-street, South Hackney.
Worboys, Thomas Saunders, L.R.C.P.Lond., Brixton.
*Yeld, Walter Harry, L.R.C.P.Lond., Stockport.

* Candidates who have not presented themselves under the regulations of the Examining Board.

UNIVERSITY OF EDINBURGH.—The following is the official list of candidates recommended to receive the degree of Doctor of Medicine, and the degrees of Bachelor of Medicine and Master in Surgery, on Aug. 1st:—

Doctor of Medicine.

*Ashdown, H. H., England.
*Ballantyne, J. W., Scotland.
†Bannerman, W. B., Scotland.
*Bentley, A. J. M'D., England.
Brodie, W. Haig, Scotland.
Brown, Harbit, England.
Calvert, Wm. H., Scotland.
Capper, Edmund, England.
‡Caw, J. M., Scotland.
†Combe, Fred. O., England.
†Davidson, R., Scotland.
‡Dickson, G. C., Scotland.
*Douglas, K. M., Scotland.
Field, Oliver, England.
Fiske, Thos. H., England.
‡Forbes, D., Scotland.
†Fraser, Peter, Wales.
Geyzel, C. W. Van, Ceylon.
‡Gordon, Thos., Scotland,
‡Haldane, J. S., Scotland.
‡Harrison, James, England.
‡Haultain, F. W. N., Ceylon.
‡Hayward, C. W., England.
*Helme, Thos. A., England.
Inkster, R. W., Shetland.
‡Jardine, Robt., New Brunswick.
Johnson, O., Sierra Leone.
‡Kellgren, A. L., Sweden.
Kennard, C. P., England.
Lawson, David J., Scotland.
‡Mackay, Wm. A., Scotland.
†Mackness, G. O. C., England.
‡M'Lean, Allan, Australia.
‡Maddox, E. E., England.
Mann, Alfred, England.
‡Miller, Ralph S., Scotland.
Montgomerie, H. M., England.
†Nasmyth, T. Goodall, Scotland.
‡Nisbet, J. Tawse, Scotland.
‡Partridge, Sydney, England.
†Purvis, Geo. C., India.
Rand, Richd. F., England.
Rhodes, Thomas, England.
Roberts, E. T., England.
‡Robinson, Thos. H., England.
‡Scott, W. E. S., England.
‡Scougal, E. F., England.
Smith, Otto Wein, Scotland.
Stephenson, Geo. S., England.
Stirling, Robert, Scotland.
Sykes-Ward, Alfred, England.
‡Sym, Wm. Geo., Scotland.
Thomas, W. Jas., Wales.
*Thomson, H. A., Scotland.
*Tillie, Joseph, Scotland.
Warnock, John, Australia.
*Waterhouse, H. F., England.
Williams, Charles L., England.
†Wood, Geo. E. C., Scotland.

* Those who have obtained Gold Medals for their Dissertations.
† Deemed worthy of competing for the Dissertation Gold Medals.
‡ Commended for their Dissertations.

Bachelor of Medicine and Master in Surgery.

*Adamson, R. O., M.A., Scotland.
†Allison, R. D. R., Scotland.
Anderson, C. A., Scotland.
Anderson, C. M., India.
Aytoun, J. H., Scotland.
Becker, J. E. A. G., England.
Bibby, J. R., England.
Bowes, A. S., England.
Branch, E. W. R., B.A., West India.
Bremner, F. P., Canada.
Bruce, L. C., Scotland.
Brunton, J., Scotland.
Bryson, L. Horner, Scotland.
Buchanan, R. D., Scotland.
Bunting, T. L., England.
Burger, B., Cape Colony.
Burton, T. J., Scotland.
Cadman, E. S. R., England.
Campbell, A. W., Australia.
Carruthers, D. A., England.
Carruthers, S. W., England.
Carr-White, Percy, England.
Carter, A. W., Cape Colony.
Cattley, Robert, England.
Christian, L. de B., England.
Clark, E. Shaw, England.
Clarkson, A., England.
Connor, S. G., Ireland.
Conyers, J. H., Demerara.
Cox, A. Edward, Australia.
*Crerar, John Wm., Scotland.
Critchley, H. G., M.A., England.
Cullen, G. M., Scotland.
Cunningham, James, Scotland.
Dardenne, Henri, Mauritius.

* Passed the examinations with First-class Honours.
† Passed the examinations with Second-class Honours.

Davidson, D. Geo., Scotland.
Day, Fredk. Arthur, Australia.
Dickson, J. R., Trinidad.
Dobie, Herbert, England.
Douglas, John J., Scotland.
Dow, A. G., M.A., Scotland.
Duncan, E. H., M.A., Scotland.
Edwards, John W., Wales.
Elder, Matthew, Scotland.
†Everett, William, England.
*Farquharson, W. Fdk., Scotland.
Fawcett, Edward, England.
Fergusson, Samuel, Scotland.
Frankish, Thomas, England.
Fulton, R. V., New Zealand.
†George, Alfred W., England.
Gibson, C. G., Scotland.
Gibson, J. A., Scotland.
Gibson, W. S., Scotland.
†Gordon, Colin, England.
Gordon, H. Laing, England.
Govan, George, Scotland.
Grindlay, Guy, England.
Haig, P. B., Scotland.
Hardie, John, Scotland.
Hislop, P. Wood, Scotland.
Holmden, F. A. A., England.
Houston, Alex. C., Scotland.
Howell, R. Edw., England.
Hudson, H. C., Cape Colony.
Hughes, Wm. H., England.
Huskie, James, South America.
Iddon, Thos. W., England.
Inglis, H. M'C., B.A., New Zealand. *In absentia.*
Jones, Peter, Wales.
Kunz, H. de D., M.A., Scotland.
*Lackie, James, Scotland.
*Laing, James H. W., M.A., B.Sc., Scotland.
*Langwill, H. C., Scotland.
Lawson, Charles B., Scotland.
Leask, William, Scotland.
Leitch, J. W., B.A., Australia.
Leschen, H. A., Australia.
Lewis, O. Richd., England.
Littlejohn, T. H., Scotland.
Luke, James, Scotland.
Lumsden, John S. S., India.
M'Allum, S. G., India.
Macdonald, John, Scotland.
M'Dougall, Wm. S., Scotland.
M'Gill, J. M., M.A., Scotland.
Mackenzie, R. P., Scotland.
M'Laren, John, Scotland.
*Maclean, Alex., Scotland.
†Maclean, E. John, Wales.
MacLeod, C. G., M.A., Scotland.
MacTier, Wm. B., Scotland.
Mann, F. William, India.
Mansel, Charles J. L., England.
Manuel, W., Scotland.
Maynard, Edw. F., England.
Meek, Wm. O., England.
Milner, E. Arthur, England.
†Monteith, James, Scotland.
Morgan, Thos. L., Wales.
Mortlock, A. Wm., England.
Mursell, Henry T., England.
Nasmyth, Alexander, Scotland.
Nicoll, F. James, New Zealand.
Oliver, Wm., Scotland.
O'Neill, Wm. H. B., Australia.
O'Rourke, William, Ireland.
Owen, Robert G., Wales.
Parham, Wm. M., England.
Parry, Chas. Paton, Wales.
Peddie, Wm. James, Scotland.
*Pilgrim, E. G., Barbadoes.
Polson, William, Scotland.
Poole, Samuel, England.
Prentice, Alex. J., Scotland.
Pretorius, P. G., South Africa.

Wilde, H. Henry, England.
*Wilkinson, George, England.
Wilson, A. F., Scotland.
Wilson, Arthur, Scotland.
Wilson, Geo. R., Scotland.
Wilson, John, M.A., Scotland.
Wilson, J. J., Scotland.
†Wimberley, C. N. C., Scotland.
Wyse, Richard, M.A., Scotland.

* Passed the examinations with First-class Honours.
† Passed the examinations with Second-class Honours.

Prizes and Scholarships. — Ettles Scholarship, Eustace Graham Pilgrim, M.B., C.M.; Beaney Prize, Eustace Graham Pilgrim, M.B., C.M.; Syme Surgical Fellowship, Alexander Eddington, M.B., C.M.; Goodsir Memorial Prize, Herbert F. Waterhouse, M.D.; Murchison Scholarship in Clinical Medicine, Arthur J. Whiting, M.B., C.M.; Buchanan Scholarship in Gynæcology, George Wilkinson, M.B., C.M.; James Scott Scholarship in Midwifery, James Lackie, M.B., C.M.; Gunning Victoria Jubilee Edward Forkes Prize in Zoology, Philip J. White, M.B., C.M.; Gunning Victoria Jubilee Christison Prize in Materia Medica, Joseph Tillie, M.D.; Gunning Victoria Jubilee John Thomson Prize in Pathology, Robert Muir, M.B.; Gunning Victoria Jubilee Alison Prize in Public Health and Medical Jurisprudence, James A. Blair, M.B., C.M.; Gunning Victoria Jubilee Simpson Prize in Obstetrics, John Wm. Ballantyne, M.D.; Dobbie-Smith Gold Medal in Botany, Gustav Mann; Cameron Prize in Therapeutics, Monsieur Pasteur, LL.D.Edin.

UNIVERSITY OF ABERDEEN.—The following candidates received degrees in Medicine and Surgery:—

Degree of M.D.

Beattie, James Walker, M.B., C.M., Sunderland.
Bryce, James, M.B., C.M., Herts.
Carmichael, Jas. Chas. Gordon, M.B., C.M., Surg.-Major, Bengal.
Collie, Frank Lang, M.B., C.M., Aberdeen.
Gordon, Henry Charles, M.B., C.M., Army Medical Service.
Lamb, John Marshall, M.A., M.B., C.M., North Borneo.
Masson, John, M.B., C.M., Lancashire.
Middleton, James Gowing, M.B., C.M., Nice.
Poonen, Eapen, M.B., C.M., B.A. (Madras), India.
Swaine, Charles Lethbridge, M.B., C.M., Army Medical Service.
Wills, Reginald Graham, M.B., C.M., Bath.

Degrees of M.B. and C.M.

Aymer, Chas., Laurencekirk.
Black, George, Auchmill.
Black, R. S., M.A., Inverness.
Counter, F. Wm., Australia.
Cox, E. T., Alton, Hampshire.
Croucher, Francis B., London.
*‡§Cushny, A. R., M.A., Speymouth.
Dale, W. C., M.A., Aberdeen.
†Dean, Geo., M.A., Aberdeen.
Fearnside, C. F., M.A., Aberd.
Fernandez, Harry E., Herts.
Forbes, F. C. F., India.
Fraser, James Beauly.
Gammack, A. P. F., Aberdeen.
†Geddie, D. W., M.A., Banff.
Glennie, J. A. R., Aberdeen.
Goodwin, W., St. Albans.
Grant, James, Tomintoul.
Jones, John E. D., Cawnpore.
Kelly, Francis, Aberdeen.
Kinnear, J. C. M., Montrose.
Lang, Gordon A., Inverness.
Little, Andrew, Kinneff.
Ludlow, Fred. Wm., Germany.
†M'Gillivray, Angus, Inverness.
M'Gowan, W. S., M.A., Aberlour.
M'Hardie, Thos., Morayshire.
M'Rae, Jas., M.A., Mintlaw.
Macdonald, Donald J., Lewis.
Mackay, A. W., M.A., Aberd.
Mackinnon, Nicol, Skye.
Mackinnon, Andrew R., Aberd.
MacFarlane, Neil M., Stanley.
MacRitchie, David, Inverness.
Mann, Chas. F. G., Grantown.
Munro, Wm. E., Dornoch.
Noble, Frederick, Aberdeen.
Philip, Alex. A., Aberdeen.
Philip, James P., New Deer.
Reid, James, Rothiemay.
Reid, Duncan, M.A., Aberdeen.
Reith, Wm. R., M.A., Aberdeen.
Rennet, David, Aberdeen.
*Rose, Alexander, Nairn.
Ross, Henry, Ross-shire.
Saram, Allan M. de, Ceylon.
Scott, Lindley M., M.A., Aberd.
Seneviratne, Henry C., L.M.S., Madras University, Ceylon.
Sheard, Wm. C., Yorkshire.
Silver, George J., Crieff.
Smith, Daniel M., M.A., Aberd.
Souter, John F., Orange, N.S.W.
Stevenson, Edgar, Birkenhead.
Sutherland, W. G., Newcastle-on-Tyne.
Taylor, William C., Aberdeen.
Thomson, William, Montrose.
Thomson, Robert, Nairn.
Trail, John M., Aberdeen.
Troup, James, Aberdeen.
Valentine, John, Montrose.
Watt, J. L., M.A., Stonehaven.

Alexander G. Johnston, Aberdeen, has passed the examinations for the degree of M.B. and C.M., but will not graduate until he has attained the necessary age.

The diploma in Public Health has been conferred on the following candidates:—

Black, R. S., M.A., M.B., C.M.
Duke, A. L., M.B., C.M.
Mason, John W., M.B., C.M.
M'Donald, D. Jas., M.B., C. M.
Stephenson, R. B. T., M.B., C.M.
Webb, E. W., M.D., Surg.-Major.

* Highest academical honours. † Honourable distinction.
‡ The John Murray Medal and Scholarship (awarded to the most distinguished Graduate of the year), Alexander Rose (being *proxime accessit*.)
§ The George Thompson Fellowship, Wm. Leslie Mackenzie, M.A. (being *proxime accessit*).

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The quarterly examinations in Glasgow for the triple qualification took place in July, with the following results:—

Forrester, Co. Antrim; Mary C. Murdoch, Elgin; Kate E. Pepper, London; Susanna R. Beck, Dorking, Surrey; R. T. Davies, Cerrig of Druidion; A. R. Huxley, Groombridge, Kent; Rosa E. Bale, Westacott, Banstable; J. M. Macmillan, Glenbarr, Argyllshire; Janet M. C. Gray, Bathgate; C. A. Foyl, Liverpool; B. Wiggins, Glengarnock, Ayrshire; J. Devon, Glasgow; J. P. T. Burke, Co. Tipperary; Lucille D. Leslie, Margate; Edith L. Nicholas, Dalston; Emily G. Kent, Rochdale; W. P. Willis, St. Louis, U.S.A.; I. Baldwin, Yorks; Janette F. A. Wallace, Inverness-shire; W. Dill, Cork; Alex. Cumming, Hull; E. Walsh, Limerick; E. R. Pollard, Burnley; R. A. Potterton, Co. Meath; R. Murdoch, Old Cumnock; E. W. F. Kirkman, Dublin; S. J. C. Soloman, Calcutta; W. Bratton, Omagh; D. Riordan, Co. Cork; J. T. Jameson, Ponteland; W. R. Abernethy, Londonderry; D. Donnelly, Kerry; A. P. Stinson, Armagh.

Second Examination.—Of 68 candidates, the following 32 passed:—T. B. Kelly, Galway; D. Doherty, Donegal; P. W. M'Gregor, Glasgow; James Hamilton, Lanark; D. M'Crorie, Kilwinning; Charlotte M. Wheeler, Coppenhall, Crewe; Elizabeth M. Harris, Calne; J. W. Wilkinson, Queen's County; Fred Hall, Bury, Lancashire; A. C. Burrows, Waterford; J. C. Sturdy, Ruswarp; T. E. Hughes, Rhyl; H. M. Bayer, Kilmalleck, County Limerick; Anne E. Wilson, Baltimore, U.S.A.; Harriet M. M. Hughes, London; T. L. Lynch, County Kerry; J. Craig, Glasgow; P. T. James, Glamorgan; S. Martyn, Bombay; C. F. Britto, Goa; R. M. Stokes, South Africa; Frank Nuttall, Bury, Lancashire; A. J. Clark, Forfarshire; G. Macdonald, Kirkintilloch; A. F. Walker, Liverpool; John Lane, County Cork; T. Davies, B.A., Victoria; J. Hodgson, Calne; R. Smith, South Australia; E. Hartley, Blackpool; A. G. Merson, Banffshire; H. C. Darbey, Cradley, Staffordshire.

Final Examination.—Of 49 candidates, the following 24 passed, and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. and S.G.:—J. Round, Dudley; J. A. Hamilton, Brighton; Edith E. Ward, London; J. P. Granger, Glasgow; A. M. Ford, Glasgow; R. A. Robinson, county Derry; R. T. Williams, Glamorganshire; F. G. Phillippo, Jamaica; E. R. P. Watkins, Abergavenny; D. H. Stephens, North Shields; R. Steel, Kilbride, Ayrshire; W. C. Lancaster, Dublin; W. P. Lonergan, Glasgow; F. Castle, London; H. F. W. de Montmorency, county Carlow; H. W. Fisher, Liverpool; T. Meiring, Worcester, Cape of Good Hope; P. Campbell, Perthshire; D. Thomson, Newcastle-on-Tyne; F. J. Woods, Banbridge; A. Ross, Edinburgh; J. R. Jones, Festiniog, North Wales; M. R. Callender, South Shields; W. A. P. Ternan, Dundee.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the recent sitting of the Board of Examiners for the Fellowship, the following gentleman passed the necessary examination, and was admitted at the August meeting of the Faculty:—

D. C. G. Bourns, L.R.C.P. Ed., L.R.C.S.I., Surgeon-Major, Army Medical Staff.

Digitized by Google

At the July sittings of the Examiners for the Licence, the following gentlemen were admitted Licentiates:—

Leonard P. Banks, L.K.Q.C.P.I., Sharnbrook, Bedford; George J. M'Coull, L.R.C.P.Edin., Ovington-on-Tyne.

At the July sittings of the Board of Examiners in Public Health, the following were admitted Diplomates in Public Health:—

Wm. Theodore Hodge, M.K.C.S., Esh, Durham; John S. Rosser, M.B., Morriston, Glamorgan.

At the July sittings of the Dental Board, the following candidates were admitted Licentiates in Dental Surgery:—

Wm. J. Royal, Weymouth; Frank P. Nattruss, Nottingham; William Wallace, M.A., M.B., C.M., Glasgow; Augustus Berkley, Brighton; John G. Biggs, Glasgow; William Geekie, Oxford.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following have been admitted Fellows of the College:

Charles B. Gaffney; William G. Hume Henderson, Surgeon-Major, Bombay Army; F. Johnson, Surgeon-Major, Medical Staff; Ignatius O'Farrell, Surgeon-Major, Medical Staff; W. B. Stokes, Surgeon, Medical Staff.

The undermentioned has received the Diploma in Public Health:—

John Henry Griffin.

CONJOINT SCHEME OF THE COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND.—The following gentlemen have passed the Final Examination:—

Arthur James Carey, Thomas J. Connolly, Samuel A. D'Arcy, William Stephen Dodd, Richard Henry Dreaper, Berkeley F. Falkner, Alfred Aubrey Ferguson, Samuel James McWatty Gilmore, Ernest Sydney Hawthorne, Charles O'Connor Hodgens, Edward Kennedy, James Kearney, George MacKey Laing, John Robert Meeke, Stanley Moore, William Scott McBride, Arthur Saul McCorniskey, Edward Morris O'Connor, Pierce James O'Connor, Eugene Paul Pentony, Daniel Power, Matthew Burke Savage, Daniel Davis Shanahan, Frederick Smith, George Jackson Smith, Robert Millner Smyth, Arthur Edward Sproulle, Frederick William Smith Stone, Ralph Storey, George Langley Tuthill, David Turner.

APOTHECARIES' HALL OF IRELAND.—The following gentlemen have been elected office bearers for the following year:—

Governor.—Charles F. Moore.
Deputy Governor.—Richard G. O'Flaherty.
Council.—P. C. Baxter, E. H. Bolland, Thomas Collins, John Evans, Robert Montgomery, Robert Montgomery Jun., Henry P. Nolan, Edward J. O'Neill, Sir J. B. Owens, Michael J. Moore, John Ryan, James Shaw, George Wyse. Representative on the General Medical Council, Thomas Collins.

INDIAN MEDICAL SERVICE.—The following is a list or Surgeons on probation in Her Majesty's Indian Medical Service who were successful at both the London and Netley Examinations on Aug. 2nd. The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley, and the combined numbers are accordingly shown in the list which follows:—

	Marks.		Marks.
*Ozzard, F. R.	6265	Jennings, Edgar	5620
†Anderson, A. R. S. ..	6020	Stiles, T. M.	5473
‡Calvert, J. T.	5705	Hendley, A. G.	5445
Ricketts, W. S. P.	5680	Jenney, G. W...	5441
Moore, C. M.	5655	Hudson, C. T...	5285

* Gained the Herbert Prize of £20, with the Martin Memorial Gold Medal and the Parkes Memorial Bronze Medal, and also the prize in Pathology presented by Sir William Aitken, M.D., F.R.S.
† Gained the Montefiore Medal and prize of 20 guineas.
‡ Gained the Montefiore second prize and the prize in Clinical Medicine presented by Surgeon-General W. C. Maclean, C.B.

MR. C. MEYMOTT TIDY, M.B., Medical Officer of Health for Islington, and Mr. A. Wynter Blyth, Medical Officer of Health for St. Marylebone, both of Lincoln's-inn, have been called to the Bar.

THE DOG MUZZLE.—A special meeting was held recently at the Animals' Institute, to offer the society medal and £10 10*s.*, given by Dr. Gale, the blind electrician, for the best humane muzzle to prevent suffering to dogs. Entries close on Aug. 21st

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.—Dr. Hyslop, assistant medical officer at Bethlem Hospital, has, as a result of the honours examination in Psychological Medicine, gained the Gaskell Prize, given annually by the Medico-Psychological Association.

CAVENDISH COLLEGE, CAMBRIDGE: OPEN SCHOLARSHIPS AND EXHIBITIONS.—Recommended for Clothworkers' Company's Scholarship: W. Abbit, Beaumaris Grammar School. Elected to Scholarships: E. Bland, Devon County School; J. G. Bourne, Merchant Taylors' School. Exhibitions awarded to P. Umney, Merchant Taylors' School; A. Barraclough, North-Eastern County School.

OBSTETRICAL SOCIETY.—The library will be closed from Aug. 19th to Sept. 19th.

PRESENTATION. — Mr. P. G. Philps, M.R.C.S., L.S.A., recently of the Queen's-road, Peckham, has been presented by his patients and friends, on his leaving that neighbourhood, with a handsome chime clock, also two large bronze figures of Mercury and Iris, and a marble clock for his consulting-room.

SMALL-POX IN JUTLAND.—A serious epidemic of small-pox is reported to have broken out at Aalborg, in Jutland, a number of fresh cases having been recorded every day for some time past. The police authorities have in consequence prohibited all public meetings and concerts in the town until further notice.

RABIES.—According to the *London Gazette*, the number of dogs in England reported, during the week ending July 27th, as afflicted with rabies, was seven, six of which were killed, whilst one died. Of the seven diseased animals, two belonged to London, two to Surrey (excluding London), and one to Middlesex (excluding London).

HOSPITAL SATURDAY FUND.—The total net product of the sixteenth annual street collection in the metropolis and the suburbs, which was made under the auspices of the Hospital Saturday Fund on the 13th ult., is now ascertained to be £5080, or £130 more than was realised on Hospital Saturday last year. This is the largest result yet attained, the least being in 1874, when the fund was first formed.

THE SWEATING COMMITTEE'S REPORT.—We understand that at a private sitting recently of the Sweating Committee of the House of Lords, a report was presented by the Earl of Dunraven, the chairman, for the consideration of the Committee. Their lorships were of opinion that the report had been prepared with great promptitude; but having regard to its voluminous and important character, it was resolved to postpone its further consideration until next session.

HYDROPHOBIA.—Three more patients who had been bitten by rabid dogs were sent last week for treatment at the Pasteur Institute in Paris, their expenses being defrayed, either in whole or in part, out of the Mansion House Fund. The patients come respectively from Shepherd's-bush, Portland Island, and Berkshire. Arrangements have been made with an hotel close to the Institute for their accommodation. The Duke of Portland has forwarded a cheque for £25 to the Lord Mayor's Fund.

THE SANITARY INSTITUTE.—The preliminary programme has been issued of the Eleventh Congress, to be held at Worcester from the 24th to the 28th of September, 1889. Congress tickets and all information can be obtained by application to the secretary, E. White Wallis, Esq., F.S.S., Parkes Museum, 74A, Margaret-street, W. The Council invite papers on all subjects relating to health and sanitary science, reserving the right, of course, to refuse unsuitable papers. A short abstract should accompany each paper, the reading of which, if accepted, will be limited to twenty minutes.

THE LATE DR. JOSEPH ROGERS by his will bequeaths £500, free of legacy duty, to trustees, to be set apart as a charitable fund and invested in consols; the dividends to be accumulated during every distinct and successive period of ten years, and at the end of each successive period applied in the payment of the same as a prize to be called the "Rogers' Prize," to the writer of the best essay on the Treatment of the Sick Poor of this Country and the Preservation of the Health of the Poor or either of such subjects. The judges of the merits of such essays to be the President for the time being of the College of Physicians and the Master for the time being of the Apothecaries' Company, or such two or one of them as shall consent to act, and if none of them shall act then the Vice-Chancellor for the time being of the University of London. And Dr. Rogers directs that if at the end of any such period of ten years no such essay should have been written in respect of such period or if, in the opinion of the judges, none of the essays shall merit a prize, then the trustees shall apply the dividends and accumulations for such ten years for the benefit of the Medical Benevolent College or some kindred institution to be selected by the trustees.

Digitized by Google

BEQUEST.—St. Mark's Ophthalmic Hospital has received £104 6s. 8d., under the will of the late Mrs. Selina Miller.

NEW INFECTIOUS DISEASES HOSPITAL.—A special meeting of the Darwen Health Committee was held last week for the purpose of considering what accommodation should be provided for the treatment and isolation of infectious diseases. This subject first received the attention of the committee some months ago, and then they decided to approach the Board of Management of the Blackburn and East Lancashire Infirmary, with a view of seeing if that body were able to allow the Corporation to fit up one of the wards for infectious cases. The Board of Management did not entertain the idea, and consequently the committee decided to erect a substantial infectious diseases hospital, and selected a piece of land as near the town as possible for the purpose.

BEQUESTS AND DONATIONS TO HOSPITALS.—The Warden of King's College Hospital, has received a grant of fifty guineas from the Drapers' Livery Company.—The Secretary of the Glamorganshire and Monmouthshire Infirmary has received a donation of £23 2s. 2d. from Mr. McCall, of Eastcheap, London.—The recent Cookery Food Exhibition, London, has resulted in a profit of £314 15s. 6d., of which the following donations have been apportioned—Great Northern Hospital, Holloway, £100; the French Hospital, Leicester-square, £100; the Hospital for Sick Children, Great Ormond-street, 10 guineas; the Evelina Hospital for Children, Southwark-bridge-road, 10 guineas; and the French Benevolent Society, Poland-street, £37 7s.—The Committee of the Hospital for Sick Children, Great Ormond-street, have received towards the Building Fund £1000 from Mr. Junius J. Morgan, and £500 from Sir Savile Crossley, M.P.—By the will of the late Mr. Henry Matthew Clarke, of 25, Mount-street, Grosvenor-square, £1000 is bequeathed to the General Hospital, Bristol.—The Court of Common Council, London, on the 1st inst., made grants to the following hospitals—namely, 200 guineas to the Royal London Ophthalmic Hospital, Moorfields, in aid of the fund for the erection of a new hospital, 100 guineas to the Convalescent Home of the Victoria Hospital for Sick Children, Margate, and 200 guineas to King's College Hospital.—The Treasurer of the Newcastle Infirmary has received from an unknown friend 100 guineas as a thank-offering.—The recent Stanley Gala and Bazaar in aid of the Liverpool Stanley Hospital, yielded, net, the sum of £5168 4s.—The late Earl of Malmesbury has bequeathed by his will £100 to the Hants Royal Hospital.

MEDICAL NOTES IN PARLIAMENT.

Poor Law Bill.

IN the House of Lords, on Friday, the 2nd inst., Lord Balfour of Burleigh moved the second reading of this Bill, Clause 1 of which extended the legal protection of the guardians in the case of children deserted by their parents to sixteen years of age in the case of boys, and eighteen in that of girls. Clauses 3 and 4 entitled the Metropolitan Asylums Board to receive into their asylums patients suffering from diphtheria, and enabled them to let their ambulances out for hire for the conveyance of fever patients from one place to another.

Cruelty to Children (Prevention) Bill.

On Monday, the 5th, the House went into Committee on this Bill. Lord Dunraven argued against the sub-section prohibiting the employment of children under ten years in theatres and other places of amusement, and denied that there was any cruelty in such employment. He moved, by way of a compromise, a proviso enacting that where it was shown to the satisfaction of a court of summary jurisdiction that proper provision had been made to secure the health and kind treatment of the children, such court might make an order of permission for their employment in such places.—Lord Herschell moved, in addition, that such permission should only extend to children exceeding seven years of age.—On a division, Lord Dunraven's proviso, with Lord Herschell's addition, was adopted by 31 against 24, and the Bill passed through Committee.

Local Government (Scotland) Bill.

On Tuesday, the 6th, this Bill, with a number of additions and amendments, passed through Committee, and the

Universities (Scotland) Bill

was read a second time. The Marquis of Lothian said that he would make a statement in reference to the Bill on going into Committee.

Royal Commission on Army and Navy Administration.

In the House of Commons, on Thursday, the 1st inst., Mr. W. H. Smith, in reply to Sir W. Bartlelot, stated that the Royal Commission had already agreed upon a preliminary report on part of the subjects submitted for their consideration. He was unable to hold out any hopes of being able to make any communication on the subject to the House so late in the session. The Commissioners hoped to conclude their final report during the autumn.

Whitewashed Cells and the Eyesight.

Mr. Macneill drew attention to the complaints of several political prisoners in Ireland that their eyes were weakened and influenced by the glare of the whitewash on the walls of their cells, and asked whether the cells of these prisoners could not be covered with a wash of blue or pink instead of the ordinary whitewash. Mr. Balfour, in reply, stated that the prisoners referred to had not complained, nor was there any evidence that their eyesight had become impaired. Replying to further questions, Mr. Balfour said he could hardly believe that the eyesight of gentlemen in prison under the Criminal Law Procedure Act was more delicate than that of persons imprisoned under other Acts, and he had heard of no complaints in the latter class of cases.

The River Lea.

On Friday, the 2nd, Mr. Ritchie, in reply to Sir J. Colomb, stated that the Local Government Board had received a letter from the Poplar Board of Works as to the foul condition of the river Lea, and mentioning the fact that the death of a boy from typhoid fever was attributed to bathing in that river. The letter also stated that the West Ham Corporation allowed their sewage to flow into the river at all states of the tide. He (Mr. Ritchie) would cause inquiries to be made as to that.

Colour Blindness.

In reply to Dr. Farquharson, Sir Michael Hicks-Beach said that the Board of Trade had referred the subject of colour-blindness among seamen to a Departmental Committee which would have scientific assistance in its inquiries. It would not be possible to present the report of the Committee before the end of the session.

Council of India Bill.

The debate on the second reading of this Bill, which was adjourned on July 25th, was resumed. Sir G. Campbell objected to any change being made in the Indian Council without full inquiry into its constitution and working, and moved the rejection of the Bill. Sir Guyer Hunter, in supporting the motion for the rejection of the Bill, urged that the Council ought to be strengthened by the addition of a medical officer of Indian experience. Important statistics affecting the health of 250 millions of people were received from India every year by the India Office, and yet there was not an officer on the Council of India who was able to deal with those statistics. Sir Roper Lethbridge concurred in the suggestion made by Sir G. Hunter, and thought it most desirable that the Council should be strengthened by the addition of a member of the Indian Medical Service. The amendment was negatived, and the Bill read a second time.

Irish Lunacy Service.

On Tuesday, the 6th, Mr. Balfour, replying to Dr. Kenny, stated that one of the inspectors of lunatics in Ireland had retired on superannuation. The question as to the necessity of filling the vacancy is under consideration. There was no foundation for the rumour that it was in contemplation to appoint one of the Scotch assistant Commissioners of Lunacy to an administrative position in the Irish lunacy service.

METROPOLITAN ASYLUMS BOARD.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THEORY OF FEVER.

Dr. Staehely (Darmstadt) is thanked for his *brochure*, which we are unable to find space to reproduce. His views upon the nature of fever and the treatment of the febrile state are mainly based upon the assumed bacterial cause of the process; for he considers that all the phenomena of the febrile condition are referable to changes induced in the blood by the presence of micro-organisms. The occurrence of the phenomena of fever apart from the presence of microbes would, according to him, be apparently attributable to blood changes similar to those they induce. His views lead him to suggest the early mercurial treatment as germicidal in its effect, followed by mild aperients; the supply of acid to aid the digestive process; the external application of cold, and the use of restorative and stimulant remedies. Apart perhaps from the advocacy of germicides (and not even in that respect is he singular), there is no novelty in his suggestions.

J. W. C.—A good treatise on responsibility in its medico-legal aspects is that of Dr. Napoleone Colajanni, entitled "La Sociologia Criminale," and published at Catania in the present year by Tropea.

M. O. H.—Sanitary leaflets are issued by the National Health Society, 44, Berners-street, London, W.

HEISCH'S TEST FOR SEWAGE.

To the Editors of THE LANCET.

SIRS,—Will you kindly tell me through your columns the particulars of Heisch's test for sewage in water? Also Kjeldahl's nitrogen process? Being such an exile is my excuse for troubling you.

I am, Sirs, yours faithfully,

Jullundur, Punjab, July 12th, 1889. R. H. FIRTH, Surgeon, M.S.

*** Heisch's test is described in Dr. Cornelius Fox's "Sanitary Examinations of Water, Air, and Food" (J. and A. Churchill, 1886), page 24. We do not remember to have seen the Kjeldahl process in a text-book; but full details are given in various recent volumes of "The Analyst." It is simple and, with proper care, very satisfactory.—ED. L.

THE JONES FUND.

THE following additional sums have been received for the appeal made in our issue of July 20th to raise a sum to meet the legal expenses (over £60) of Mr. Jones of Edmonton:—

Sums already acknowledged	£21 18 0	G. Borlase Hicks, Esq. ..	£1 1 0
Lennox Browne, Esq. ..	1 1 0	E. Hooper May, M.D. ..	0 10 6
		H. G. Sworn, Esq... ..	0 5 0

Further subscriptions will be gladly received by Dr. J. W. Hunt, 101, Queen's-road, Dalston, N.E.

DARWINISM AND PHYSIOLOGY.

THE Darwinian theory has exercised the most marked influence on morphology among the biological sciences, while physiology, as one of the same group, bears the fewest and slightest traces of that influence. Dr. J. Steiner, Professor of Physiology in the University of Heidelberg, has set himself to apply to his special subject the Darwinian methods and processes which have borne such striking fruits in morphology. He begins with the nervous system, and his treatise, of which the first and second parts are published, is entitled "Die Functionen des Centralnervensystems und ihre Phylogenese, von Dr. J. Steiner, a.o. Professor der Physiologie an der Universität, Heidelberg. Braunschweig: Friedrich Vieweg und Sohn." His book is hailed by many of his fellow-workers in Germany as a new departure in physiological science, fraught with important results for medicine, theoretical and practical.

J. E. E.—We cannot find room for the letters. But our correspondent seems justified in his complaints against Mr. P—— for seeing his patient independently and without waiting for the consultation which had been arranged. Mr. P—— may have had some excuse for haste and not waiting. But even so, an explanation should have been vouchsafed without delay.

"MEDICAL ADVICE FREE: MEDICINE 2D. PER BOTTLE!"

To the Editors of THE LANCET.

SIRS,—In answer to "M. L. S." in your last issue, allow me to point out that if the distribution of handbills is not touting, I should like to know for what purpose these bills are printed and distributed? That they have been widely distributed is well known to myself and other medical men for some time past. I myself have collected at least twenty amongst my own patients, and I have also observed them under the street knockers. To call this not touting is perfectly ludicrous, and a mere quibble. Your correspondent informs us that this is a dispensary instituted and supported by the lady doctor herself and her private friends; but on turning to the Medical Directory, I find that this "twopenny private dispensary" is placed amongst our public hospitals, and that the lady doctor in question terms herself the "Senior Medical Officer to the Fentiman-road Dispensary, and Resident Medical Officer and Lecturer on Midwifery, Clapham School of Midwifery." *O tempora, O mores!* I wonder what next! If lady practitioners are to be permitted to establish schools of midwifery, and have the privilege of advertising the same at ridiculous fees, the sooner the fact is known and put a stop to the better.

I assure you, this correspondence has not been begun and carried on with a feeling of spite against lady practitioners; but we expect that when they set up practice amongst us they will not entirely set at defiance a little of the honour and dignity of the profession.

I remain, Sirs, yours faithfully,

Aug. 4th, 1889. PRO BONO PUBLICO.

MEDICAL ADVERTISEMENT BY A GRADUATE OF THE LONDON UNIVERSITY.

THE following is contained in a handbill:—

"Jalap in Jam: or Whimsical Wisdom. Mens & Corpus, Limited, or 'No Premium Required': A quaint and humorous 'Guide to Health,' pleasant to read, and useful to ponder. The cheapest 'Life Insurance Policy' ever yet introduced. By F. J. Money, M.D. (Lond.), &c. LIFE IN TASMANIA.

To the Editors of THE LANCET.

SIRS,—I should be obliged if any of your correspondents could inform me of the conditions of life in Tasmania, and if there is an opening for practice in any part of the island.—I am, Sirs, yours faithfully,

Aug. 7th, 1889. EMIGRANT.

ANOTHER MEDICAL ELECTRICIAN SUPPORTED BY A QUALIFIED MEDICAL MAN.

ONE Edward Moross, who advertises his miraculous cures as a medical electrician in the *Daily Telegraph*, finding Manchester too narrow for him, has come to London. Electricity is his sheet-anchor. But even that agent has its limits; and for the greater success of catering for those who believe in a properly qualified medical man he has "associated himself with Dr. Swyer, and they practise together as

Edward Moross and Dr. Swyer, 17, Euston-square
(near Euston Station), London."

It would be satisfactory if the bodies whose diploma is held by Dr. Swyer, or the Medical Council, would inform him that this use of medical qualifications is inconsistent equally with public advantage and professional dignity. For a qualified medical man to be advertised with, and play second fiddle to, and support an electrical quack is worse than giving the care of a branch practice to an unqualified man.

Dr. Allwright.—If possible, next week. The article, however, has extended to a greater length than we anticipated.

TREATMENT OF HYDROCELE BY SOLUTION OF CORROSIVE SUBLIMATE.

LETTERS having been received from correspondents inquiring the meaning of "a 1500 per cent. solution," mentioned in Mr. Barnard's letter inserted in our impression of the 20th ult., page 147, we referred the query to the writer, and the following is his reply:—

"SIRS,—By a 1500 solution I meant about ⅔ grain of corrosive sublimate in an ounce of water. Any chemist, if asked a 1500 solution of corrosive sublimate, will dispense the required injection.

"I remain, Sirs, yours truly,

"B. BARNARD, M.B., &c.

"Victoria-street, Alderney, July 31st, 1889."

H. L.—The best edition of the works of Dr. John Freind, the learned Court physician and historian of medicine, who flourished in the early years of last century, is that superintended by the medical scholar Wigan, well known for his labours on the text and interpretation of Aretaeus. Its full title is:—"Johannes Freind, M.D., Serenissimae Reginae Carolinae Archiatri, Opera Omnia Medica. Londini: Typis Johannis Wright. MDCCXXXIII." For this edition Wigan translated from English into flowing Latinity Dr. Freind's "History of Medicine," which is better known, particularly on the Continent, in this revised Latin version. The "Opera Omnia" fill one entire volume folio, of which there is a fine copy in the Library of Trinity College, Cambridge.

Cyclops.—Yes.

AN APPEAL.

To the Editors of THE LANCET.

SIRS,—Mr. George Couper Sanders, M.R.C.S., L.S.A., practised in the Island of Jamaica about seventeen years ago. About the year 1874 his wife died, and about two years later he left the island, and no one there has since heard of him. He left a daughter aged four years totally unprovided for. A gentleman on whom she had no claim has kept her until now, when he is no longer able to. An aunt (not in good circumstances) would take the girl, if we can get the necessary money to provide an outfit and pay her passage to England. Will you kindly lend your aid in trying to get the necessary £50 or so for the orphan of one of our professional brethren. I shall be glad to receive and acknowledge any contribution and answer any questions.

I am, Sirs, yours faithfully,

A. W. THORBURN STEER, M.R.C.S., L.R.C.P.,
Government Medical Officer, Jamaica.

Puslinch, Yealmpton, Plymouth, Aug. 2nd, 1889.

DOCTORS AND PHARMACISTS IN MEXICO.

La Voz de Hipocrates, a Mexican periodical, complains bitterly of a piece of legislation which has just been enacted by the important State of Yucatan. Henceforth doctors of medicine and surgery will be permitted to open pharmacies without giving them in charge to registered pharmacists—that is to say, medical men may keep chemists' shops with or without the help of unqualified assistants. Unfortunately, something like this is occasionally done in this country, where open surgeries are sometimes left in the charge of the proprietor's wife, or of some much less competent and more irresponsible person.

A CAUTION.

To the Editors of THE LANCET.

SIRS,—I have a son named James Henry Clark, a medical man of eminence at St. Elizabeth, Jamaica, who holds a Government appointment there, and has held the appointment for about twenty years. I have recently been informed that some man over here is using my son's name and referring to my son's medical education and qualifications, and thus endeavouring to obtain money from the benevolent public. I therefore ask you to allow me to state in the columns of your valuable journal that my son is at present in a good position, and has never required, and I trust never will require, to ask for pecuniary help, and that if any person should be applied to for assistance in the name of my son he will promptly hand over to the police the person so applying, or report the matter to my solicitor, Mr. Basil E. Greenfield, 31, Nicholas-lane, E.C. I am, Sirs, yours faithfully,

Vartry-road, Clapton, N. THOMAS HENRY CLARK.

MEDICAL EVIDENCE IN FINLAND.

A CASE of appeal has just been decided by the Appellate Court of Finland, which upheld the judgment of an inferior court where a medical man refused to give evidence in a case where the interested parties were his patients, considering that he was bound by the oath he took on receiving his licence to practise not to reveal circumstances which had been confided to him by those under his care. For this refusal he was fined. It seems therefore that the obligation to maintain professional secrecy is not recognised in Finnish courts of law any more than it is in this country. As to this matter the law varies in different countries, that of France, for example, recognising and enforcing secrecy under all circumstances.

M.R.C.S.'s (Dovercourt) letter has been mislaid. Will our correspondent kindly repeat his question?

ABRIDGED REPORT OF THE

President's Address,

Delivered at the meeting of the British Medical Association, Leeds,

BY C. G. WHEELHOUSE, F.R.C.S.

THE PRESIDENT, in his opening remarks, gave a cursory review of the progress of medicine and of medical education, and described the medicine of the early ages, laying stress upon the comparative isolation of practitioners in former times. He drew a sketch of the general practitioner of the early part of the present century, explained the method of surgical operations in former times, and pointed out that a surgical operation in those days was an ordeal of fearfully different magnitude to anything known to us to-day, and, naturally enough, the patient had a large say in the matter. Courage and endurance, unfortunately, are not given alike to all, and many a life which would be saved to-day was at that time voluntarily laid down, not simply for want of faith in the capability of the surgeon, but from sheer inability to face the terrible ordeal of bodily suffering involved.

Referring to the apprenticeship system, Mr. Wheelhouse said the practitioner was not called upon, on entering the profession, to prove himself in any way specially adapted for it. It mattered not what his education or want of it had been, no test was required of him. In the majority of cases he was, as it were, in a manner born to the position, as well as to the particular practice in which he was destined to take part; and, under any circumstances, he was called upon to serve an apprenticeship so prolonged as to be almost the same thing. For the first five years of his professional life he was compelled to devote himself to what seemed, perhaps, at the time, the simplest and most abject drudgery; but at the same time he picked up, all unconsciously it may have been, but none the less certainly, knowledge destined to be of infinite value to him in after life—the knowledge of common diseases; and when, after his few short months of hospital experience, he entered on practice, he did so with a fair all-round idea of its ordinary requirements, and he trusted to extraneous help in emergencies and unusual difficulties. He next came to the medical science of the present day, and compared it with the medical education and medical examinations in the past.

Upon the subject of Medical Education in the Present, the President spoke as follows: "Year by year and little by little we have been accumulating a burden which, if not absolutely more than the shoulders of the student can bear, is yet heavier than he can possibly carry with credit; and, instead of increasing his opportunities to acquire the strength necessary to bear it, we have curtailed his time, have deprived him of material advantages, and, in accordance with the hurry of the age, have demanded results well-nigh impossible of attainment. The five years of apprenticeship have been swept away, and with them the opportunity to master the groundwork of medical education and to acquire a sound knowledge of the more common forms of ordinary illness has gone also; and in four years, instead of eight, we permit the whole work to be completed. We have determined to ignore the utility of that homely but infinitely useful form of preparation for the higher parts of medical education which apprenticeship or pupilage was pre-eminently calculated to afford; we have determined that from the day on which a boy has been able to pass a very ordinary and limited educational examination he shall be permitted to take his place in a medical school, and we have arranged a curriculum which, if by dint of slavish toil he can master, shall enable him at the early age of twenty-one to enter upon the full responsibilities and duties of practice. We demand of him that he shall pass *at least* four examinations. One in general education; then a preliminary one in his professional subjects at the end of his first year of professional study; a "primary" and a "pass" examination; and, to make this the more easy to him, we permit him, if he wishes to do so, to split up these four examinations into eight or even ten, and, by clearing them off in fragments, we give him the opportunity to dismiss study after study from his mind with a rapidity which leaves scarcely a trace of them behind, and enables him to forget them, one after another, with a facility which, if the mere capability to pass examinations were the only end and object aimed at, would be commendable enough; until at last there only remains the one final test, at which, by a supreme effort, he may show that he has attained a sufficient amount of theoretical knowledge to satisfy his examiners, and that he has acquired a fair comprehension of the principles which underlie his future work. That even this is impossible, or nearly so, is abundantly proved by the fact that in a large majority of cases men voluntarily, and in many more under the compulsion of failure in the earlier examinations, devote five years instead of four to their education, and find that even then the task has been almost more than their powers could endure. To make up for deficiencies which even to themselves are then only too apparent and too keenly felt, hospital appointments, whether paid or unpaid, are eagerly sought for and accepted; or, failing to obtain these, men seek for themselves assistantships in which they may obtain that practical knowledge which only work under the guidance of experience can give them, and for lack of which they feel and know that they are unfit to cope alone with the responsibilities of practice. In one thing the new system is unquestionably superior to the old. It takes its stand upon a higher grade of education, both general and professional; and of two men educated, one on the old and the other on the new plan, when they have been equally for a few years in practice the latter will probably be the better practitioner of the two. He will then have picked up what the other had already acquired to begin with, and will henceforward easily distance his competitor in the race. But I do not envy him the experience of those first five years. The General Medical Council, with a laudable desire to diminish the evils of unqualified practice, has determined as far as it is possible to put down the employment of unqualified assistants, and it thereby unquestionably aids the young and recently qualified practitioner in his attempt to complete an education which ought to be complete already. But there are two sides of this question, and it has to be regarded from the point of view of the employer also. He, when engaging an assistant, is presumably seeking the service of one who will be a help to him, and not of one who, though nominally an assistant, is in reality a pupil, and who, though he be very learned in all the highest wisdom of the schools, is startled by the appearance of so extraordinary a rash as that presented by 'sudamina,' for instance, and who, though he can tell an examiner glibly enough the number of days necessary for the incubation of varicella, rubeola, variola, or scarlatina, and all the theoretical details concerning the history, course, complications, development, and sequelæ of these various diseases, is 'not quite sure,' when he *sees* them, which is which, and would therefore like his principal to see them before he ventures upon their treament. ..... I know there are many men who feel strongly that this is the time when pupilage would be most advantageous, and in the discussions of the Education Committee of the General Medical Council, as well as elsewhere, I have heard it strenuously argued; but the view is one which does not commend itself to my judgment, and which a long course of observation has not tended to confirm. The most advantageous time for pupilage is when the mind is eager, inquiring, impressionable, and plastic; when mistakes and failures are of comparatively little moment, when a little wholesome ridicule may be borne with equanimity, and when lessons which are the outcome of inexperience leave well-defined impressions on the mind which serve as warnings and landmarks at a future and more important age without any bitterness or sting in their remembrance. ..... I would earnestly plead also for a radical change in our modern system of examinations That they are capable, as at present conducted, of great improvement will, I think, be very generally admitted. That they fail in their essential object—the discovery of those who are fit and of those who are unfit to enter upon the responsibilities of practice—is undeniable; and while I admit that the effort to do this is always conscientiously and most praiseworthily pursued, I

Digitized by Google

am satisfied that they often—far too often—wholly fail in the attainment of their intention. During a long career as a teacher, systematic and practical alike, I have watched with the keenest interest the success or failure of those whom I have trained, and many and many a time my heart has failed me when I have seen those whom I have known to be conscientious, painstaking, and thoroughly well-informed men sent down, while others of whose records I should have been sorry to speak have passed with flying colours."

After referring to the great and unnecessary multiplication and costliness of the examinations, the hurry and worry under which they are conducted, and the ordeal to the examiner, the President continued: "Now can this, I would ask, be necessary? Is it a fair way to ascertain what a man truly knows? Can it be just either to candidate or examiner? To each one of these queries I give an emphatic No; and you may very reasonably ask me how I would propose to remedy the evil. Years ago I suggested to the Council of the College of Surgeons that much, at any rate, of this difficulty might be overcome by conducting the written portion of the several examinations at the seats of teaching as is done with the University local examinations. The question papers could be forwarded under the seal of the examining body to the official in charge of the local examination room. The seal could be there broken in the presence of the candidates, and the examination could be so safeguarded as to render collusion as impossible as in London or elsewhere. To the candidate such time as he felt that he honestly needed could be given, and the element of hurry, at any rate, so far as he is concerned, could be eliminated. The answers, when handed in, could be sent, again under seal, to the examiners with absolute safety, and all this at an almost nominal cost. The examiners, in their turn, could take reasonable time in which to form an accurate judgment of each set of papers; and last, and most important of all, those of the candidates who so entirely failed as to make all hope of their passing an impossibility, might be informed that that was so, and that their presence for further examination was not, on that occasion, necessary. By this plan time, labour, money, and heartburning would be saved, and a feeling of justice and fairness, unquestionably lacking under the present system, would be engendered; and, as with this, so the same proceeding could be carried out with all the other examinations. And yet, as examinations are at present conducted, one great thing would be lacking: they would lack any guarantee of the possession by the candidate of that *practical* knowledge which we some of us feel to be the great want in modern medical education. This I, if I could have my way, would thus supply. I would make the first step in the purely medical part of the curriculum a year, at any rate, of practical pupilage. So soon as the "preliminary" or educational examination had been passed, I would insist that the next step should be residence for one year either with a general practitioner, or as a pupil at a county hospital, or in connexion with a recognised public dispensary where, under the observation and guidance of the acting officers, the pupil might see, day by day, the general run of every-day practice, and would become familiarised with the common ailments of daily life as seen in the homes of the people; where he would become acquainted, and that practically, with all that he would be called upon to undertake, or would meet with in the early years of actual practice; where all the simple and minor operations of surgery would be seen and learned in the best, because most practical, manner. Then I would send him for at least four full years to a medical school and hospital, to learn the why and the wherefore of all that he had already picked up, and to learn all that is so admirably taught in those most admirable schools. I would not permit him to fritter away his examinations in scraps; but, at the end of the second year, I would institute one full one, to embrace all the preliminary studies which had occupied him so far, and, by delaying all else to the end of the curriculum, I would compel him to keep all his knowledge well in hand, and would then institute such a full and complete examination, both theoretical and practical, as should be an indisputable guarantee of his possession of the requisite knowledge to make him a safe and reliable practitioner. This is done now in Germany, and the example is one we should do well to follow. At that examination I would also have placed in the hands of the examiners a minute and careful analysis, drawn up by the teachers, of the character of every candidate; this should be accompanied by a certificate of his pupilage, and should declare, on the responsibility of those under whom it was served, that he had been made conversant with daily out-door practice, and had himself performed the common operations of minor surgery. At any rate, whatsoever may be the course that future examinations may take, I sincerely hope their number will be diminished, that they will become more and more practical in their character, and that they will be made to include a knowledge of every-day occurrences, rather than of such as are likely to come but rarely under observation. Further, I confess to being sufficiently old-fashioned to desire to return, in a greatly modified form, to some system of pupilage by which a true foundation may be laid, by an early acquirement of the knowledge of common things, for that vast superstructure which the medical practitioner of the future will be called upon to raise and carry. I have now endeavoured to recall to your memory the character, the achievements, and the capability of the practitioner of former times. I have shown you how infinitely greater is the knowledge and the utility of the practitioner of the present day. We know how he has brought every region of the body, even those which were formerly deemed wholly beyond the sphere of his influence, such as the contents of the cranium, the vital organs of the chest, of the abdomen, and of the pelvis, under the dominion of our science; that, by the institution of preventive medicine, he has swept away many of the opprobria and of the direst scourges of former times; and it only remains to indicate in very few words the still vast field of further utility that lies open for cultivation by the practitioners of the future. There is one plague spot, I fear, which even he will fail to conquer, which will remain to fester, to kill its thousands, to maim, disfigure, and to sap the health of millions, of deserving and of undeserving alike, and, as the great curse of humanity, to baffle all our efforts to arrest the progress of disease, and to render them futile and abortive. You know the curse to which I allude—the curse that steadily and vindictively pursues the track of licentiousness, of ungoverned passion, of hateful sensuality; and you will admit with me that so long as human nature remains what it is, and is left in unbridled possession of the means of gratification, no ray of either light or hope will fall on that dark track. Some day men may have become sufficiently enlightened to submit to necessary legislation and restrictions on this and cognate subjects; but until they do, the foul stream of syphilis will continue to meander hither and thither and whithersoever it will through the world of life, will poison its springs, will wither even its fairest blooms, and destroy its richest fruits without selection and without mercy. By the cultivation of bacteriology and cognate sciences, by a deeper and more profound acquaintance with natural phenomena and laws, I can foreshadow in my mind the time when the whole range of zymotic and exanthematous diseases will have been subdued and conquered; when the seeds of each will have been isolated and so studied that their individuality will be recognisable; the soils in which they will grow and those in which they will lie sterile will be known and appreciated, and be brought under cultivation by the hands of the medical men of the day; when the methods of dealing with them will be such that they may be reduced to harmless quantities; and when, by the spread of sanitary science, the whole human race may be protected from their evil influences. It will not be in our day that these mighty triumphs will be won, but our successors will undoubtedly achieve them; and the time will certainly come when the kingdom of disease will be so closely narrowed down that only the necessary accompaniments of the changes and vicissitudes of natural laws, the evils attendant upon the wilful disobedience of those laws, the innumerable accidents to which life and limb must be for ever liable, and the inherent defects and deficiencies in the harmonious working of the parts of a machine so exquisitely and delicately constructed as is the frail body which for a time we inhabit, will be the only kingdom in which the professors of medicine and surgery will be called upon to exercise their sway. Then will the victory of our science be complete, and the day will have come when the world will be called upon to acknowledge that the labours of the physician and the surgeon—patient, enduring, untiring as they have been through all time—have not been in vain, and have reached their final consummation."

ABRIDGED REPORT OF THE

Address in Surgery.

Delivered at the meeting of the British Medical Association, Leeds,

BY T. PRIDGIN TEALE, M.A., F.R.C.S., F.R.S.

"DETAIL IN SURGERY" was the title selected for this address, in which Mr. Teale hoped to show how much some of the triumphs and shortcomings of modern surgery were made or marred by the carrying out of detail, detail which was essentially embodiment of principle, not the mere multiplication of points of practice such as might not materially further the end in view. In working out this line of thought, he hoped to be able profitably to employ the time at his disposal, and to give prominence to conclusions which had been formed during a surgical life of over thirty years, made up not of his own work alone, but very largely of the freest interchange of thought and experience with most friendly and active-minded colleagues, medical and surgical, with whom it had been his great happiness to be associated. In doing so, it had been his endeavour to be as little egotistical as was compatible with the attainment of the end in view.

Speaking of Ligature of Arteries, Mr. Teale said: "It happened not long ago that I had to deal with a wound of the brachial at the bend of the elbow. Esmarch's tourniquet enabled me to expose beautifully to the eye a longitudinal slit in the artery. Of course I was obliged to apply a ligature on both sides of the puncture. There were then clearly exposed to view the two ligatures and about half an inch of the artery containing the slit. It occurred to me to divide the artery between the ligatures, and so to relieve obvious tension. I then appreciated what I had never before fully realised in connexion with ligature of an artery, the immense elasticity of the arterial coats. The separated ends receded fully half an inch from one another. The question at once occurred to me, Can it be right ever to tie an artery by a single ligature, and to leave this powerful force of elasticity to work for ulceration of the coats and gaping of the ulcer, with the risk of final disturbance by retraction of the divided ends when ulceration has completed its work? May we not here find an explanation of the numerous failures of ligature of the great arteries of twenty and thirty years ago, and of the fatal secondary hæmorrhages, chiefly from the distal end? Some may say that antiseptics and the cutting short of the ligature have changed all that, have reduced the risk of ulceration of the coats of the artery and of secondary hæmorrhage. Well, antiseptics fail now and then; and if they should fail we may be thankful for the additional protection of a doubly tied divided artery. Secondary hæmorrhage and fatal result will be thereby rendered extremely improbable."

Referring next to the subject of Stricture, the speaker said there was a form of instrument for the treatment of stricture which had been but little written about, and, although at last slowly making its way into use, had not met with the attention which he felt sure it deserved. It was known to him by the name of "Lister's sound," and was invented by Sir Joseph Lister. From the very commencement of his professional life he had been familiar with and had been taught to use in the treatment of stricture "bulbed" steel sounds, and which seemed to have existed as traditional instruments in the Leeds Infirmary. The virtue of the bulb was that, the stem of the instrument being necessarily smaller than the bulb, as soon as the bulb passed through the stricture the instrument was free, and the touch of the surgeon was at liberty to perceive the character of the succeeding part of the urethra. Compared with the bulbed sound, the ordinary catheter, which as a student he frequently witnessed in use in the treatment of stricture, was clumsy and eminently unsatisfactory. The defect of the bulbed sound, in common with most other methods of treating stricture, was that as soon as one size had been passed through a stricture, the same process of difficulty had to be encountered in passing the size larger. The principle of the instrument was this. It was bulbed at the point, like our old bulbed sounds. Then, after the narrow neck, the stem gradually increased until it attained, at a point about four inches from the bulb, a calibre two sizes larger than the bulb. Thus: No. 1 at the bulb swelled to No. 3 or 4; No. 9 to 12; No. 11 to 14. It was clear then that if you could once pass No. 1 safely into the bladder, you had prepared the way by the thickness of the stem for the more easy introduction of a sound with a bulb of the size of No. 2, and so on, each number passed rendering the way more easy for its successor. As a matter of fact, the larger sizes were passed with constantly increasing facility. It obviated the need of catheters with the hollow eye capable of carrying concealed poison, of gum-elastic catheters, and catgut bougies with the possibility of septic material lurking in interstices and cracks, and reduced very greatly the need of perineal section or internal urethrotomy. Rigors were extremely rare after the use of Lister's sounds. This rarity of rigor he was inclined to attribute to the fact that in nearly every instance dilatation had been carried at the first sitting, up to 10, 11, or 12. In a small number of cases he had failed to introduce Lister's No. 1, but these were got over by the aid of Teevan's filiform guide, which in every case was successfully passed. The guide having been introduced through the stricture, its outer end was then screwed into the tip of a conical sound, like Lister's with the bulb cut off. The filiform bougie guides the solid instrument through the stricture, and thus dilatation up to 4 or 5 Lister is secured, with the usual easy sequence, up to 12 or 14.

Coming next to Effective Drainage, he said it might be defined as "such a provision for the escape of fluid from any cavity as shall secure that the discharges, which when secreted are sweet, shall escape from the cavity before they have time to putrefy, and shall be received into one of the aseptic absorbent materials with which surgery is now so abundantly provided." Formerly the idea of drainage was almost limited to "free incision and a dependent opening." This idea was true to a certain extent and in some cases, of which the following was a brilliant example. A man was received into the Leeds Infirmary suffering from pneumothorax on the left side, from broken rib. The air was rapidly absorbed, but shortly the pleural cavity became full of fluid. This was drawn off twice, and on the second occasion was purulent. For some reason or other, the patient being extremely ill, an opening was made into the chest in front. He continued to lose strength and flesh, became extremely emaciated and albuminuric. As a forlorn hope, an incision was made into the pleural cavity posteriorly, whereby a free, dependent, self-draining opening was secured. In three months the wounds had healed, the patient had gained three stones in weight, had lost his albuminuria, and was well. But a dependent opening was not always the most efficient or the best. He was requested by his colleague, Mr. Mayo Robson, to see with him a lady with pelvic suppuration discharging through the rectum—that is, by a dependent opening. It was the source of much pain and of occasional febrile attacks and ill-health. A tumour about the size of an orange, and supposed to be the source of the pus, was felt by rectum and vagina. Mr. Robson carried out the following treatment, agreed upon at their consultation: Having exposed the tumour by direct abdominal incision, he stitched the peritoneum of the edge of the incision to the upper surface of the tumour, leaving a small area of the tumour exposed, and rendered thereby extra-peritoneal. He then cut into the tumour until he reached a collection of offensive pus, and washed out and drained the cavity. Immediately pus ceased to appear by rectum—that is, by the downward drainage—and in four weeks the whole was healed and the patient was well.

Until recently surgery has been too much a slave to the principle of a dependent opening. A dependent opening may be for the moment efficient whilst the cavity is distended, and yet, after it is emptied and collapsed, may become valvular and inefficient. Moreover, when a large cavity has been emptied the walls may by their collapse shut off portions of the surface from satisfactory drainage. Drainage, therefore, is a detail which needs to be studied in reference to each individual case. The leading idea should be so to provide, whether by position of openings, by shape of opening, or by use of drainage-tube, that secretions shall escape from every part before they have time to become septic. This idea of drainage, combined with the principle of rendering a cavity extra-peritoneal, was the key to some of the recent masterly developments of abdominal surgery,

Digitized by Google

whereby deeply seated cavities containing offensive and septic materials could be treated with comparative safety.

Another detail in surgery which he had only recently learned to appreciate was that of the independent stitching of the peritoneum. The looseness of the attachment of the peritoneum to the abdominal wall allowed it to be dealt with with great freedom. A few months ago, when he was about to stitch up the abdominal wall after ovariotomy, Mr. Hartley, who was assisting, asked, Why not stitch up the peritoneum alone, and then unite the rest of the abdominal wall by a separate set of stitches? The speaker at once acted on the suggestion, knowing that it had been practised by others. The effect was to make the closing of the abdominal wall much simpler, and not more tedious. The advantages appeared to be (*a*) absence of tension on the peritoneal union, (*b*) very little bleeding from the peritoneal stitches, and (*c*) greater facility in uniting the abdominal wall, from not having to provide for the accurate adaptation of the peritoneal edges. After the operation the patient seemed to be more free than usual from discomfort in the wound. It was possible that further advantages might accrue, such as diminished proneness to hernia of the scar, and less liability to suppuration in the track of the sutures.

There was a detail in operations on the rectum or anus which, rightly carried out, contributed very greatly to ease in operating, to the comfort of the patient after the operation, and to the permanency and perfection of the result. As a preliminary step, in every operation on the rectum or anus, there should be dilatation of the sphincter ani by the fingers. To some this might seem a truism, a self-evident proposition, which it were waste of time and breath to assert. The fact, however, was that it was far from self-evident to many surgical minds, and had not been acted upon as a general rule, and, until very recently, had been absolutely ignored by many rectal specialists, and by writers on general surgery. First and most conspicuous in this relation were bleeding internal piles. Some twenty-five years ago he was asked to operate for bleeding piles on a gentleman about thirty years of age. On mentioning the case to his father, he said, "Dilate the sphincter, and most likely you will never have to operate on the piles; they will be cured." His anticipation proved to be correct. The advice was acted upon, and the gentleman had remained well to the present time. He rarely now operated on internal hæmorrhoids without having previously tested the effect of simple stretching of the sphincter. In more severe cases, requiring the removal of hæmorrhoids, the stretching, as a preliminary to operation, at once displayed the piles to view, and placed them in a ready position for being seen, seized, and dealt with. Another advantage was that, after the operation, the parts remained at rest, and the wounded tissues were not liable to protrude and to be strangled by a resentful sphincter. Also, if there were bleeding, there would be great facility for the escape and discovery of the blood, and therefore less danger of concealed hæmorrhage, which might fill the rectum with a large clot, perhaps only to be suspected from the pallor and feeble pulse of the patient. A further advantage was that wounded and granulating surfaces within the rectum were not interfered with or kept in a painful or irritable state, after the fashion of fissure, by an over-active excitable sphincter.

Two cases had recently been under his care in which long-continued suffering after removal of piles, without stretching of sphincter, was at once cured by simple dilatation. Contrast with that the clumsy and unscientific plan until recently recommended in the text-books of requesting the patient to "bring down" the piles by sitting over hot water before operation, so as to afford the surgeon an opportunity of playing hide-and-seek with the elusive hæmorrhoids, aided by their confederate sphincter.

In operations for fistula in ano, dilatation of the sphincter was an essential preliminary. If the internal orifice were close to the anus, it would be at once displayed or brought within easy reach. If it were at some distance, and beyond the sphincter, this proceeding rendered it possible to cure the fistula without extending the incision up to the internal orifice, and so risking loss of control over the action of the bowel, by too free division of the sphincter ani. Such deeply burrowing fistulæ he had cured on several occasions in the following manner. The sphincter having been freely dilated, the external orifice of the fistula was enlarged laterally in such a way that the opening in the skin was the base of a triangle, with its apex at the other end of the fistula, where it communicated with the bowel. The track of the fistula was freely scraped, and a drainage-tube was inserted, so as to reach within half an inch of the opening into the bowel. Undoubtedly the key to a successful result in such a case was the "detail" of dilatation of the sphincter, which by its relaxation allowed the contents of the bowel to pass away easily, and without forcing secretions backwards into the fistula, until time had been given for the freshly scraped surface to unite and seal the offending track. Of late years, the question of dilatation of the os and cervix uteri, and of treatment of the cavity of the uterus for endometritis and other metritic troubles, had come very much to the front. Indeed, it was a selected subject of discussion at the present meeting in the Obstetric Section. In some of the discussions by gynæcologists he noticed that much was said of constipation as a factor in these cases, and as one that ought to be treated and remedied, of course, by medicines, as a preliminary to any special interference with the uterus. In some cases he knew, and in many others he suspected, that the cause of the constipation was a tight, or spasmodic, or irritable sphincter. In such a case stretch the sphincter, and you might "throw physic to the dogs." And there were instances in which the sphincter might cause constipation and its train of symptoms, without any evidence of fissure, or anal pain, or bleeding, or there might be what he had often observed, but had never seen described, a peculiar rigidity, a sort of inelastic ring, like a fibrous degeneration of the muscle, which did not resist the introduction of one finger, but barred the rectum as with a ring of iron to the introduction of two. In such cases only artificially softened evacuations could escape. Might they not consider dilatation of the sphincter to be a "detail" in surgery worth study no less by the physician than by the surgeon?

On the subject of Ether *versus* Chloroform he wished to speak with a sense of grave responsibility—the more so that he had to express views which were strongly opposed to those uttered at Glasgow last year by his predecessor in that chair, and his plea was as follows: "For the first fifteen years of my surgical life, which includes ten years as surgeon to the Leeds Infirmary, I knew little of any anæsthetic but chloroform. So far, probably, our experience runs parallel. During the last fifteen years ether has almost superseded chloroform in my practice. Here the parallel ceases. Sir George Macleod's second fifteen years are still devoted to chloroform. He cannot speak from fifteen years' experience of ether. As a result of the comparison of these two periods I unhesitatingly assert that ether is, for safety to the patient and for comfort and convenience to the operator, immeasurably the better anæsthetic of the two. Ether can be given '*tute, cito, et jucunde!*' I say can be; would that I could say *is* always so given." There were many hospitals in England, and still more, he believed, in Scotland, where the use of ether was practically unknown, or where, if ether was given, the obsolete towel or the grid, or the very inferior inhaler of Ormsby was used; or even should the hospital possess a Clover, it might not possess an etherist who knew how to use it to the best advantage. To administer ether badly was to bring it down nearly to a level with chloroform as to safety and to render it inferior to chloroform as to comfort to the patient. A bad etherist would cause fear, coughing, distressing sense of suffocation, excitement, struggling, blueness of lips, mucous rattling in the trachea and bronchi. He would take many minutes, five to ten, in getting his patient under the anæsthetic, would use twice or thrice as much ether as was needful, would keep his patient when unconscious overcharged with ether in a state of profound stertor, and would now and then set up a dangerous bronchitis. A good etherist would win the confidence of his patient, even of the most timid, by judicious encouragement and by first applying the mouthpiece alone. As confidence became established, he added the reservoir, and then the indiarubber bag, slowly turning on the ether as tolerance of the vapour became established, and unconsciousness began to steal on. Then he more rapidly increased the proportion of ether, and the patient quickly fell into complete anæsthesia. Such an administrator would, in nine cases out of ten, have his patient ready for operation in two or three minutes, and not infrequently in about a minute and a half, without a struggle, without coughing, often without even a transient sense of suffocation, and with the expenditure of about half an ounce of ether, and would but need about one ounce of ether for each quarter of an hour that the anæsthesia was kept up. In such a case they need fear no danger at the time, or

Digitized by Google

subsequent bronchitis. But there was another side of the ether question which he had never seen adequately stated. The advantages to the operator of using ether instead of chloroform were very great. In the first place, his anxiety was less, his fear of a fatal issue was less, and when obliged to trust to an inexperienced administrator, as he must do at times in sudden emergencies, he could more efficiently keep an eye on the patient's condition, and superintend the administrator, than when chloroform was used. In the second place, there was a saving of time, a patient being brought under the influence of ether in two or three minutes, whereas chloroform, in his experience, needed eight or ten. Such a saving was of no slight moment in modern hospital practice now that the sphere of surgery had become so enormously extended. In the third place, under ether return of consciousness to pain generally lagged behind the return of mental perception, and thus anæsthesia could easily be re-established without interrupting the operation. So marked was this fact towards the end of a prolonged operation, that sometimes the surgeon might continue to operate for ten minutes or a quarter of an hour without reapplication of the inhaler, and even converse with his patient whilst stitching up a wound. This was hardly, or rarely, the case with chloroform. Let anyone who was not yet a convert to ether, or who, having used ether, was wavering in his allegiance to it, asked himself these questions, "Have I myself studied the details of successful etherisation? Am I using the best form of inhaler? Have I taken pains to have those who act for me properly taught and trained? If not, let him ask himself one more question: Have I done my duty?"

An essay on "Detail in Surgery" would hardly be complete without some words about "instruments." It was often difficult to get the best type of instrument, or to renew a lost form, so great was the tendency to degeneration, and departure from the original type. Take as an illustration one of the simplest and most frequently used, a "scalpel." How rare it was to meet with a scalpel of good form, and yet they had the pattern admirably drawn in the work on "Surgery," by that master hand in the selection, designing, and handling of instruments, Sir William Fergusson. Another simple, universally used instrument was the "director," which was rarely met with of good form, as generally offered for sale. A director should be capable of being held firmly, the handle being substantial, not thin, long enough and not stumpy, and horizontally roughened and not slippery. The metallic catheter or sound is, or was, an instrument used by nearly every medical man. As with the scalpel so with the catheter; the surgeon should be able to feel—that is, to be conscious where the point of the catheter or sound was, and without seeing it, as he could not have his eye upon the point when in use.

After referring to and explaining the uses and best forms of make of the "vulsellum forceps," the twitch tourniquet, and torsion clamp, Mr. Teale concluded as follows:—"Those of my hearers and readers—for an address to the British Medical Association is practically delivered *urbi et orbi*—those, I say, who have expected to hear a triumphant record of the astonishing progress of surgery, or a pæan on our local surgical achievements, may be disappointed at the humble theme which I have attempted to work out, and may think that I have failed to do justice to colleagues who have done much to leave a mark upon the progress of surgery. My aim has been not to sound the praise of individuals, much as they deserve it, but rather to leave an impression on the practice of surgery. If any of you shall have been induced to study afresh, and from the point of view put forward in this address, the question of division of an artery between two ligatures, the bearing of the sphincter ani upon the surgery of the rectum, and disturbed functions of the colon; the substitution of Lister's sounds for older methods in the treatment of stricture; the emancipation of "drainage" from red-tape rules; and, lastly, the proper method of administration of ether so as to raise it as an anæsthetic to a position of incontestable superiority to chloroform—if such should be the outcome of this address, your time in listening will, I trust, not have been wasted, and my labour in composing it may not have been in vain."

AT a meeting of the Glasgow Town Council last week, Dr. Russell, medical officer of health for the city, reported that already 583 deaths from measles had been registered this year, which will be known as the year of the severest epidemic of measles since 1871.

A CASE OF

PAROXYSMAL HÆMOGLOBINURIA WITH EXPERIMENTAL OBSERVATIONS AND REMARKS.

BY JOHN S. BRISTOWE, M.D.,
AND
S. MONCKTON COPEMAN, M.A., M.B.

(*Concluded from page 259.*)

HITHERTO I have given only a bare narrative of the case and of the experiments performed in relation with it. I now proceed to make a few remarks upon some of the more interesting or important matters comprised therein.

1. The relation of paroxysmal hæmoglobinuria to Raynaud's disease has of late often been observed and commented upon. The case I have brought forward is apparently a further illustration of the fact. For there can be little doubt that the so-called frost-bite of the toes which marked the beginning of the patient's malady was an example of Raynaud's "symmetrical gangrene"; and the frequent "dying" of his fingers, and their occasional mottling when exposed to cold, are further evidence of the tendency in his case to spasmodic contraction of the smaller arteries characteristic of that affection.

2. The experiments all go to confirm the view that the primary obvious phenomenon in paroxysmal hæmoglobinuria consists in a rapid and often apparently enormous destruction of the red corpuscles of the blood, and that this depends on the direct influence of cold. On the eight occasions on which determinations of the number of corpuscles before and after exposure to cold were made with the hæmocytometer, the results were so far identical that, without exception, a large diminution in the number was observed after exposure—the loss varying in the different experiments between 129,000 and 824,000 per cubic millimetre. The fact that the blood-corpuscles were injuriously affected is further shown by the loss of consistence and variability of size and shape of the survivors, by the presence in the blood-plasma of granular masses of hæmatin, and also by the tinting of the plasma by the escaped colouring matter of the corpuscles. The extreme rapidity with which the destruction of the corpuscles was effected was shown in some cases by the examination of the blood immediately after exposure of the patient to cold, and before any of the characteristic symptoms of the attack had revealed themselves. Indeed, the specimen of blood which showed an apparent loss of 824,000 corpuscles per cubic millimetre was taken a quarter of an hour only after the patient had come out of a cold bath, in which he had lain for no more than ten minutes. But there is reason to believe that the destruction went on at a diminished rate for some little time after exposure, for in the fifth experiment the blood examined just after exposure contained 2,970,000 red corpuscles per cubic millimetre, while that examined about two hours later contained only 2,890,000. That the destruction of the red corpuscles in the case under consideration was due directly to cold seems obvious. During the whole time the patient has been in the hospital he has had no attacks of his malady, excepting those brought on experimentally by such exposure; and these have all been, so far as we can judge, proportionate in their severity to the duration or intensity of the cold applied. This view of the causative influence of cold is confirmed by the effects of placing his hands only in cold water, and especially by those of the immersion in water of a ligatured finger.

3. The experiments show that the destruction of red corpuscles did not affect the condition of the urine until some little time (from half an hour to three hours) after the commencement of the exposure causing that destruction. In the majority of cases the morbid products found in the urine were hæmoglobin in an amorphous form, and albumen in about sufficient relative quantity to render it not improbable that this also was simply derived from the disintegrated corpuscles, and was not, or was only in a slight degree, the albumen of the plasma.[1] A certain amount of

[1] See in reference to this matter the note containing an account of further investigations by Dr. Copeman, appended to this paper; also Fagge's "Principles and Practice of Medicine," vol. ii., p. 589, second edition.

Digitized by Google

acid hæmatin was found in many of the experiments associated with the hæmoglobin; but it was clearly demonstrated by those experiments, in which the urine was passed and examined every quarter of an hour, that the blood-colouring matter as excreted by the kidneys was hæmoglobin alone, and that the acid hæmatin was simply due to the decomposition of the hæmoglobin in the bladder, or subsequently to its escape from the bladder. Any doubt there might be on this point was removed by two experiments: one already referred to in connexion with the second experiment on March 18th; the other of which I reproduce in Dr. Copeman's words, as follows: "The persistent presence of acid hæmatin in the urine after an attack has been considered a difficulty, as physiologists are agreed that there is no free acid in the urine. The following experiment was therefore devised, with the object of seeing whether it was possible to obtain acid hæmatin artificially by the action of urine on blood. Some urine was passed into a small flask until it was nearly full, when it was covered with an indiarubber cap and placed in the incubator at a temperature of 98·6°. It was perfectly clear, of acid reaction, and sp. gr. 1015. A rabbit having been killed, its blood was removed, defibrinated, and rendered laky by alternately freezing and thawing it several times, thus avoiding the use of any drug. It was then slowly filtered through several thicknesses of paper and allowed to fall drop by drop into the urine. When the latter was fairly tinted, and the flask at the same time had become full, the cap was replaced, and the flask was left in the incubator for three hours, about the usual time at which, after exposure, the patient passes the first specimen of bloody urine. On then removing a small portion of the contents, the colour was seen to be quite different to that of the hæmoglobin which had been used; and, on examining it with the spectroscope, the bands of acid hæmatin were well seen, the wide absorption band in the blue being even better marked than usual." A very important fact was observed in the ninth experiment, in which exposure on a fairly warm day was followed by a comparatively slight but unmistakable destruction of corpuscles, with only moderate elevation of temperature—namely, that no hæmoglobin whatever appeared in the urine, but in its place albumen. The results of this experiment accord to some extent with the observations of Ponfik, who has shown that, whilst the injection of large quantities of hæmoglobin into the blood causes hæmoglobinuria, the injection of small quantities causes no such elimination. It seems, therefore, a legitimate inference that, when the unwonted destruction of red corpuscles in cases of so-called hæmoglobinuria is comparatively small, albumen alone appears temporarily in the urine, the hæmoglobin of the destroyed corpuscles being used up in the system, probably by being converted into biliary and urinary pigments, and that when the unwonted destruction is larger the discharge of hæmoglobin accompanies that of albumen.

4. In every experiment, exposure to cold was followed by rise of temperature. The highest point varied on different occasions from 99·2° to 103·4°, and was attained within from one to two hours after the exposure which produced it. There can be no reasonable doubt that this febrile temperature was due to the destruction of blood-corpuscles. It is an interesting fact that, excepting one or two cases in which the phenomena were exceptionally mild, the duration of the attack, counting from the end of exposure to the subsidence of the consequent fever, was almost exactly five hours. The abnormal condition of the urine was, however, apt to last a little longer.

5. It is noteworthy that not only, as has been shown, was the destruction of blood-corpuscles rapid and enormous, but that the restoration of blood-corpuscles was also remarkably rapid. Thus, in the course of the fourth experiment the corpuscles per cubic millimetre were reduced from 3,612,500 to 2,930,000; at the end of six days they had risen again to 3,540,000; and in the fifth experiment the corpuscles fell to 2,970,000; four days later they amounted to 3,450,000.

6. Lastly, I may venture to make a few remarks with respect to the nature of hæmoglobinuria. Its association with Raynaud's disease is, as I have before remarked, a fact of common observation. What is the connexion between them? I confess that, notwithstanding this frequent association, I doubt if there be any relation between them other than the fact that the paroxysms of both are apt to be induced by the same cause—namely, exposure to cold. In the one case, it is the nerves and walls of the bloodvessels which suffer; in the other, it is the blood, and possibly the blood-producing organs. The relation of hæmoglobinuria to pernicious anæmia has been well discussed by Dr. Hunter in his work on the pathology of the latter disease. He shows that in both diseases the essential factor is the undue destruction of the red corpuscles of the blood; that in pernicious anæmia this takes place within the portal system, and the hæmoglobin is almost wholly got rid of in and by means of the liver; while in hæmoglobinuria the destruction takes place in the systemic circulation, and the bulk of the products of this destruction escapes with the urine. It is perhaps needless to add that, although the bloodlessness of pernicious anæmia is more uniformly progressive and persistent, and as a rule becomes more intense than that in hæmoglobinuria, the phenomena of anæmia are for the most part the same in both. In hæmoglobinuria, not only does pallor supervene, but the patient may acquire an icteric tinge, there may be hæmic murmurs, capillary pulsation, &c., and, as Dr. Copeman has shown, hæmoglobin crystals may appear in the blood prepared for microscopic observation—a phenomenon which he has observed in the blood of pernicious anæmia and that of hæmoglobinuria, but never in healthy blood. I suppose it will be admitted that, although the destruction of red corpuscles is the primary obvious phenomenon of hæmoglobinuria, there must be some antecedent peculiarity of the blood which renders the blood-corpuscles unduly amenable to the deleterious influence of cold, otherwise we should all be sufferers. As to what this peculiarity is, and how it is induced in the first instance, I will not venture to speculate. But I cannot help suspecting that paroxysmal hæmoglobinuria is only an exaggeration of a natural tendency. The red corpuscles of the blood are constantly undergoing destruction; but the products of this destruction are used up in the system, and (at any rate in health) do not appear in the urine in the form either of hæmoglobin or of albumen. Dr. George Johnson, Dr. Mahomed, and others have called attention to the fact that temporary albuminuria is apt to occur in apparently healthy persons after cold bathing And Dr. Ralfe, in an exceedingly interesting paper, published in THE LANCET last November, discusses the subject of paroxysmal albuminuria, and shows, from his own experience, that this affection is apt to occur in persons otherwise apparently healthy, after exposure to cold, fatigue, or mental worry, and (excepting that he has rarely observed elevation of temperature) with symptoms practically identical with those characteristic of hæmoglobinuria. Indeed, he expressly states that in four of his cases the paroxysmal albuminuria occurred in persons who had suffered from hæmoglobinuria, and he considers that there is a definite relationship between the two affections. Is it not probable that, at any rate in those cases in which the paroxysmal albuminuria is due to cold, the albuminuria is specially related to the undue destruction of red corpuscles caused by the exposure, and is in fact (as was the case with my patient in the ninth experiment) an undeveloped form of hæmoglobinuria, the *petit mal*, so to speak, of that disease? I need scarcely add that there is no reason to suppose that either in paroxysmal hæmoglobinuria or in paroxysmal albuminuria the kidneys are the seat of disease, or that they act in any other capacity in relation to them than as simple organs of elimination.

[*Note.*—After the reading of the paper experiments (which had been contemplated) for the purpose of determining the source of the albumen in the urine were made by Dr. Copeman, who furnishes the following memorandum.]

May 12th.—An attack was induced with the object of determining, if possible, the nature of the albumen passed. The patient placed his hands in iced-water (temperature 40° F.) for ten minutes, having previously emptied his bladder. A specimen of urine was obtained immediately after exposure (No. 1), and again at intervals of fifteen minutes for an hour and a half. No. 1 was quite normal. Nos. 2, 3, 4, 5, and 6 contained albumen; No. 5 contained also a slight trace of blood pigment, as shown by the guaiacum reaction. The specimens containing albumen were then saturated with magnesium sulphate and left for the night, by which means the globulin present was precipitated. Next day the precipitate was filtered off and the fluid again saturated with the salt to ensure complete precipitation, and again filtered. The filtrate was then acidified with dilute acetic acid and gradually heated to 80° C., when

Digitized by Google

a precipitate of serum-albumen appeared. This, on being allowed to settle, was found to be less than half of the amount of the globulin previously obtained, so that when the paroglobulin normally present in the serum (which is usually from 3 to 4 per cent.[2] as against 4 to 5 per cent. of serum-albumen) is allowed for, there was a considerable excess of globulin, the presence of which could only be accounted for on the supposition that it was derived from the splitting up of the hæmoglobin of the red corpuscles.

With regard to the form in which the pigment from the broken-down corpuscles is passed by the kidneys, the method of drawing off the urine at frequent intervals has shown that it then consists of oxy-hæmoglobin, while if this substance be allowed to remain in the bladder for some hours in contact with the acid urine it finally becomes converted into acid hæmatin. From an experiment made April 29th, however, it appears that it passes through a preliminary stage of met-hæmoglobin before becoming finally converted into acid hæmatin. A difficulty in determining this point was at first experienced, since the spectrum of met-hæmoglobin and that of acid-hæmatin are practically identical, each showing four absorption bands (Hoppe-Seyler), although in most text-books only three bands are shown in that of met-hæmoglobin. The two bodies can, however, be distinguished by the fact that met-hæmoglobin when treated with a reducing reagent such as ammonium sulphide becomes converted into reduced hæmoglobin, while with similar treatment acid hæmatin yields reduced alkaline hæmatin.

In the specimens of urine obtained from the patient in the earlier experiments the four absorption bands were always well marked; and this, together with the fact that a spectroscope showing a scale of wave-lengths was not at hand, led to the conclusion that acid hæmatin was always voided. Later observations show that this may not invariably have been the case, although undoubtedly it was so in many instances. In point of fact, the degree of change appeared to depend solely on the length of stay in the bladder; so that, according to the time which the urine had remained there, oxy-hæmoglobin, met-hæmoglobin, or acid-hæmatin was obtained.

ON THE

STATE OF THE CIRCULATION IN THE EXTREME VESSELS IN ATROPINE AND COCAINE POISONING.

A SUPPLEMENT TO THE ARTICLE IN "THE LANCET" OF JULY 18TH, 1885, ENTITLED "ON THE MECHANISM OF THE ESTABLISHMENT OF VASCULAR CONGESTION—AN EXPERIMENTAL RESEARCH, DEDICATED TO STUDENTS OF MEDICINE."

BY T. WHARTON JONES, F.R.C.S., F.R.S., &c.

IN the third edition of my "Ophthalmic Medicine and Surgery" (1865, page 141), it is recorded that in the course of researches on the state of the blood and the bloodvessels in inflammation[1] I found that the application to a frog's web, displayed under the microscope, of a solution of the sulphate of atropia (four grains to the ounce of water) was followed by *constriction* of the calibre of the arterioles of the part acted on, in about the same length of time that dilatation of the pupil supervenes on the dropping into the eye of the same solution. As constriction of the calibre of arteries is owing to contraction of the circularly disposed muscular fibres composing their middle coat, it follows that the *modus operandi* of the atropia in this case must consist in exciting contraction of the said fibres. If we watch the process under the microscope, we see the contraction gradually take place, as indicated by the thickening of the muscular wall *pari passu* with the resulting constriction of the calibre of the arteriole.[2] The circular muscular fibres of the middle coat of the arterial wall are under the control of the sympathetic nerve, as are also the radiating muscular fibres of the iris. The action of atropia in dilating the pupil is, as I long ago showed, by exciting through the sympathetic nerve contraction of the radiating muscular fibres of the iris, and is, therefore, of the same nature as its action in causing constriction of the calibre of arteries. Apparently from overlooking the difference in respect to arrangement of the *radiating* muscular fibres of the iris on the one hand, and of the circularly disposed muscular fibres of the arteries on the other, persons from whom a better judgment might have been expected have not scrupled to express themselves as unable to understand how, under the influence of one and the same therapeutic agent, the pupil should become *dilated* and the calibre of arterioles *constricted*.

The effect of constriction of the calibre of arterioles—or, as it is commonly designated, tension—is to impede the free flow of blood through those vessels into the capillaries and thence into the venous radicles, the result of which is that accumulation, aggregation, and stagnation of red corpuscles therein are permitted to take place. In the article in THE LANCET to which this paper is a supplement, I remarked that authors, professors, orators, and the young gentlemen misinstructed by them, assuming to know all about nature's works better than nature herself, have scouted the idea that the establishment of congestion of blood could take place except by a "primary active dilatation" of all the vessels found to have become distended in the affected part, produced by the operation of a supposed mechanism under the influence of imaginary vaso-dilator nerves. They seem to have observed so imperfectly the sequence of phenomena, and reasoned so illogically from what they saw, supposing them to have ever taken the pains to look to see at all, as to be unable to detect how the congestion becomes established by progressive retention, accumulation, and aggregation of red corpuscles in the capillary network and venous radicles in consequence of *primary constriction* of the arterioles (under the influence of *really existing* vaso-constrictor nerves) which lead thereto, whereby the force of the current is impeded; so that the blood not being duly driven onwards, *stasis* in the said vessels takes place by aggregation of the red corpuscles. The passive dilatation by distension of the vessels thereby occasioned is increased by the additional quantity of blood which is regurgitated into them from anastomosing capillaries and venous radicles to which collateral arterial channels, in which the flow of blood may be still going on, directly lead. The red corpuscles of this blood aggregating also, dilatation by distension with stagnant blood becomes complete in the implicated capillaries and venous radicles, as well as in the arterioles leading thereto.

We thus see that the mechanism of the establishment of vascular congestion from gradual accumulation and *stasis* of aggregated red blood-corpuscles in extreme vessels, when the arterioles leading to the affected part are *primarily constricted* under the influence of their vaso-constrictor nerves, is the opposite of the simple vascular fulness which immediately takes place when, in consequence of a relaxed state of their walls, however induced, the calibre of the vessels yields to *passive dilatation by distension* with full and rapid streams of blood in them and in the capillaries and venous radicles to which they lead.

In atropism or belladonna poisoning the pupils are dilated, the pulse small, the face pale, the surface of the body cold, and the fauces dry; symptoms which indicate:—the first, contraction of the radiating muscular fibres of the iris—the others, constriction of the arterioles (from contraction of the circular muscular fibres composing their middle coat) with impeded circulation in the extreme vessels. Supervening on these symptoms, a rash breaks out on the body owing to patches of congestion from accumulation of red blood-corpuscles in capillaries and venous radicles by the mechanism before described. The accompanying delirium and other general nervous disturbance, again, arise from congestions of similar mechanism in the brain and spinal cord. The influence of the belladonna passing off and return of the arterial walls to their normal state of tension thereby taking place, the circulation in the extreme vessels resumes its freedom, and so the congestions gradually become dispersed. The pupils at the same time recover their habitual width and mobility in consequence of the dilator muscular fibres ceasing to overpower the action of the sphincter pupillæ as well as the physical elasticity of the structural framework of the iris itself, which, when unopposed by muscular action, tends to bring the pupil to a middle width, as is seen in the eye shortly after death. Different from this, it is to be noted, the pupil is found widely dilated in the eye of a dead bird, as will be explained below.

In cocaine poisoning Dr. Montalti found, as recently reported, the tongue, mouth, and fauces quite dry, the mucous membrane blanched, the body bedewed with a cold sweat, the pulse small and rapid, with symptoms of general nervous disturbance. In another case, in which death took place, the body was cold, the face pale, the lips livid, the pupils dilated, and the pulse imperceptible. On examination post mortem, intense congestion of the brain and spinal cord, as well as their membranes, was found. These symptoms, it will be observed, are similar to those in atropism or belladonna poisoning, and indicate constriction of arteries, with impediment to the free flow of blood, followed by congestion from retention and accumulation of blood-corpuscles in the extreme vessels, in the manner already explained. Had *vaso-motor paralysis* really been the effect of the action of the cocaine, as Dr. Montalti supposes, the calibre of the arteries would have become dilated by distension with full and rapid streams of blood in them, so that the increased activity of the circulation in the extreme vessels would have given rise to flushing and warmth of the surface of the body.[3]

In the eye of a dead bird the pupil is found, as before mentioned, very much dilated, whereas in the human eye, after death, it is found of middle width. This state of the pupil in the human eye depends, as I showed more than fifty years ago, on physical elasticity of the structural framework of the iris, which during life is in antagonism to the action of the sphincter pupillæ muscle on the one hand and the dilator pupillæ muscle on the other; and which, after death, when the contractile power of these two muscles is abolished, brings the pupil into the middle state of width. In the iris of the bird's eye there is no dilator muscle of the pupil, but there is a strong sphincter pupillæ, composed of transversely striped muscular fibres, which are most probably voluntary in their action. The completely dilated state in which the pupil is found in the bird's eye after death is owing to strong elasticity contracting the substance of the iris and retracting its pupillary edge towards its ciliary insertion. The fact that there is no dilator pupillæ muscle in the bird's eye explains how it is that atropia does not excite dilatation of the pupil in the living animal. It would have been otherwise if, as used to be erroneously supposed, atropia acted by paralysing the sphincter pupillæ, and thus giving scope to unrestrained action of a dilator.[4]

A good many years ago there appeared in the Proceedings of the Royal Society the abstract of a paper denying that the application of atropia solution to the frog's web is followed by constriction of the calibre of the arterioles of the part acted on, and denying also that an effect of constriction of arterioles could be congestion of blood in the capillaries and venous radicles to which they lead. Nay, more than this, the author of the paper, adopting the "*ignoratio elenchi*" argument, erroneously attributed to me the contention that congestion is owing to constriction of *all the vessels*—arteries, capillaries, and veins—*of the affected part*, and then proceeded to demolish the phantom he had thus conjured up. The paper, the author of which was a young graduate, was communicated to the Royal Society by Dr. Bastian, his professor of pathological anatomy. I do not know whether his professor of physiology was consulted in the matter; but on a different occasion Dr. Sharpey lent his assistance to an inquiry as to the action of belladonna on the pupil—whether it consists in exciting contraction of the radiating muscular fibres of the iris or paralysing the sphincter pupillæ. A report of this coming under my notice, I sent to one of the medical journals a reference to the exposition of the subject which had been before the profession many years in the successive editions of my "Ophthalmic Medicine and Surgery." Any further continuation of the "experimental research" referred to was thus superseded.

The question of the alleged escape of white blood-corpuscles from the interior of small vessels is always cropping up; thus at a late meeting of the Pathological Society the President, in his eulogistic obituary notice of the late Dr. C. J. B. Williams, claimed for him to have been one of the earliest investigators who traced out the migration of corpuscles. If by this was meant the escape of white corpuscles from the interior of small vessels, he attributed to Dr. Williams a mistake which I do not think he ever committed. If the President will refer to Dr. Williams's "Principles of Medicine," he will find that Dr. Williams supposed the colourless corpuscles which accumulate on the inner surface of the walls of small bloodvessels, as seen under the microscope, to be new formations. This, as I showed forty-five years ago, was a mistake, certainly, but very different from that attributed to him[5] in supposing that white corpuscles escape from the interior of small vessels. The very opposite—viz., that white corpuscles make their way from without into the interior of small vessels—might, with less unreason, have been deduced from Dr. Williams's words.

Ventnor.

[3] In explanation of all this, see my article in THE LANCET, entitled, "Dilatation of the Calibre of Small Arteries: is it a fact in nature, disclosed by experimental research, that dilatation of small arteries is *primary* and owing to an active expansion of their walls under the influence of special *vaso-dilator* nerves? An inquiry addressed to physiological authors, professors, and occasional orators." (For earlier discussions on the subject of congestion, see my articles in the British and Foreign Medical Review for 1842 and 1844.)

CANCER OF THE MALE BREAST, BASED ON THE RECORDS OF ONE HUNDRED CASES; WITH REMARKS.

By W. ROGER WILLIAMS, F.R.C.S.,
SURGEON TO THE WESTERN GENERAL DISPENSARY, AND SURGICAL REGISTRAR TO THE MIDDLESEX HOSPITAL.

(*Concluded from p. 263.*)

Metastatic deposits in the bones.—Of these 91 cases, metastatic deposits in the bones were noticed in 5. Subjoined is a brief abstract of these cases:—

1. The patient, aged forty-two, had a mass of hard cancer, the size of a hen's egg, occupying the right breast, which infiltrated the overlying skin and the axillary glands. It was of eight years' duration. The breast was amputated, and the axilla cleared out. On microscopical examination, alveolar fibrous cancer was found. Three months later there was recurrence of the disease in the chest. Shortly afterwards, in raising his arm, spontaneous fracture of the right clavicle occurred, and at the seat of fracture a cancerous tumour soon formed. Subsequently cancerous growths developed in both tibiæ. He died of asthenia a year after the operation for the primary disease. At the necropsy the whole of the soft parts of the right mammary region were extensively infiltrated by a dense fibroid cancerous growth, which had invaded the subjacent ribs and the sternum by direct extension. There were metastatic deposits in both clavicles and tibiæ, as well as in the liver.

2. The patient, aged forty, came under observation with ulcerated scirrhosis of breast, and extensive nodular infiltration of the skin and adjacent soft parts and axillary glands. The disease was of five years' duration. He died shortly afterwards with secondary deposits in the sphenoid and base of skull.

3. This man, aged forty-five, had a hard nodular cancer of the right breast, with infiltration of the overlying skin and axillary glands. No operative treatment was undertaken. He died with extensive cancerous growths in the vertebræ and other bones. The total duration of the disease was thirteen months.

4. The disease began as a hard nodule the size of a marble in the right breast, a year before the patient came under observation. It soon increased to the size of a walnut, and the axillary glands became enlarged. The patient, whose age was forty-five, was emaciated, and, after he had been under treatment but a short time, he sustained spontaneous fracture of the right humerus at its lower third when turning in bed. About this time he complained of pain in all the limbs, and he died shortly afterwards with symptoms of secondary disease of the lungs.

5. This patient, aged forty-eight, had ulcerated scirrhous cancer of the left breast of four months' duration, and a cancerous growth of the left clavicle.

Treatment and result.—Of 56 amputations of the breast for primary cancer there were 2 deaths—a mortality of 3·6 per cent. The mortality after amputation of the female breast I have found to be 11 per cent. In 20 of these cases the axillary glands were removed as well;

[5] See my Report on the Present State of Knowledge of the Nature of Inflammation, in the British and Foreign Medical Review for April, 1844.

Digitized by Google

the 2 fatal cases belong to this category. Both of them died of septicæmia about a month after the operation. With regard to the other cases, the ultimate result is stated only in 3; in all there was recurrence: (1) in the axilla two years and three-quarters after the operation, with subsequent invasion of the thorax by direct extension; (2) in the chest three months after the operation, and death twelve months later, with metastatic deposits in liver and bones; (3) in the chest a few months after the operation; this was destroyed with caustic several times, but it returned and increased rapidly. The average period of convalescence in 8 of the above cases was thirty days. In the other 36 cases the axillary glands were not touched. All of these recovered. The average period of convalescence in 6 cases was eighteen days. The ultimate result is mentioned in 14 cases as follows: One was well eleven years after the operation, and quite free from recurrence; another died six years after of apoplexy, without any recurrence. In the other 12 cases there was recurrence—in the chest in 9, opposite breast in 2, and the axilla in 1. In 6 of these the recurrent disease was extirpated; all recovered from the operation. The ultimate result was as follows: 1. Four months after amputation of the breast for the primary disease, there was recurrence in the opposite breast. This was amputated. There was no further recurrence in either chest or axilla; but two years and a quarter after the last operation a recurrent nodule formed in the skin of the hand, which was successfully excised. 2. At the primary operation both breasts were amputated. There was recurrence a year later in the left axilla. This was excised. The disease recurred six years later in the left chest and axilla. Two years later he was reported dying from invasion of the thorax by direct extension. 3. Soon after amputation of the left breast for primary cancer, recurrence was noticed in the chest. In the course of ten years it increased to the size of an orange, and several discrete hard nodules developed at the axillary end of the scar, but there was no obvious affection of the axillary glands. At the end of this time the recurrent disease was excised. There was no subsequent disease in the chest or axilla; but eleven years afterwards the patient died with metastatic growths in the liver and in the cardiac part of the stomach. 4. There was recurrence in the chest seven months after amputation of the breast for the primary disease. This was excised, but there was further recurrence soon afterwards. 5. The disease recurred in the opposite breast a month and a half after amputation of its fellow for the primary disease. This breast was also amputated; he was convalescent ten days later. 6. Recurrence in the chest eight months after amputation of the breast for the primary disease. Four months later this was excised. This disease subsequently recurred in the chest and axilla.

Initial seat of the recurrent disease.—This was noted in 14 cases:—In 10 the disease was seated in the mammary region. (No glands were removed at the primary operation in 4; glands were removed at the primary operation in 2; not stated in 4.) In 2 it was situated in the opposite breast. (No glands in either case were removed at the primary operation.) In 2 it occupied the axillary glands. (At the primary operation the glands were removed in 1, and not touched in 1.)

Causes of death.—In 18 fatal cases the causes of death were as follows: asthenia, with metastatic growths, in 7 cases; invasion of thorax by direct extension in 6 cases; not stated in 2 cases; septicæmia (after operation) in 2 cases; apoplexy (without any recurrence) in 1 case.

The necropsies.—Of these only 10 were recorded. There were metastatic deposits in 7 cases, or in 70 per cent. In 44 necropsies for cancer of the female breast I found metastatic deposits in 28 cases, or in 63 per cent. In the other 2 cases the thorax, lungs, &c., were invaded by direct extension. In these 7 cases the metastatic deposits were situated as follows: in the liver in 3 cases, lungs and pleura (both 2, right 1) in 3, and bones in 3; kidneys (both) in 1 case; bladder in 1; peritoneum in 1; stomach (cardiac part) in 1; and pancreas in 1. The following were the bones affected: both clavicles and tibiæ, the vertebræ and other bones, the sphenoid and base of skull, each in 1 case. Thus of these 10 necropsies there were metastatic deposits in the bones in 30 per cent. Of 44 necropsies for cancer of the female breast, I found the bones affected with metastatic growths in 9 cases, or in 20 per cent. The particular bones involved were as follows: the femur (both, 2; right, 1; left, 1) in 4 cases, the humerus (right, 1; left, 1) in 2 cases, the tibia (right) in 1 case, the ribs (both) in 1 case, and the lower dorsal and upper lumbar vertebræ in 1 case.

I will now conclude with brief abstracts of the cases of cutaneous epithelioma and melanotic cancer.

Cutaneous epithelioma of the male mamma.—Of this there are three cases.

1. This patient, aged sixty-three, came under treatment with a hard cancerous ulcer of the mammary region the size of a walnut. It was of a year's duration, and ulceration began after the disease had existed for six months. He had experienced several hæmorrhages from it. The disease was extirpated. The histological examination was made by Cornil, who described it as an example of "épithéliôme pavimenteux lobulé," which probably originated in the skin of the areola.[1]

2. The age of the patient was forty-seven. He came under treatment with a hard cancerous ulcer of the breast and infiltration of the axillary glands. The disease was first noticed five years previously as a hard lump at the left nipple. Ulceration began eighteen months ago. On microscopical examination it proved to be "squamous-celled[2] carcinoma."

3. A tall, thin, dark, neurotic man, aged forty-one, came under observation with epitheliomatous ulceration of the areola, in the midst of which the nipple was still visible. The disease seemed to consist of indurated plaques in the skin, which were movable over the subjacent soft parts. In the edges and base of the ulcer a blackish tint was obvious. The axillary glands were enlarged. He stated that the disease began five years previously as a small wart in the skin of the areola; ulceration set in six months ago. His mother died, aged sixty, of cancer of the bowels. His previous health had been good, although he had suffered from dyspepsia and emphysema. He had led a regular life under favourable conditions. The breast was amputated, and the axillary glands removed. On microscopical examination it proved to be a case of melanotic cancer of the skin of the areola, and the axillary glands were similarly affected. The patient recovered from the operation, but recurrence set in before complete healing of the wound. This was destroyed by Vienna paste; but it rapidly recurred in the chest and axilla. One year after the first operation he was in a moribund condition, with extensive recurrent disease invading the thorax and secondary disease of the liver.[3]

Cutaneous epithelioma of the female mamma.—The following is the only case on record of a similar disease in the female. The patient was fifty-three years old, and she suffered from hereditary tuberculosis. She was the mother of four healthy children, all of whom she suckled. In February, 1885, superficial swelling of the left areola was first noticed, which in April began to ulcerate. In December the left mamma appeared full and the nipple projecting; the skin of the areola was replaced by a hard, shallow, epitheliomatous ulcer, the edges of which were hard and irregular; its base, uneven and hard, secreted a yellowish-red watery discharge. The subjacent mammary gland was hypertrophied, but not involved in the disease. There was no obvious infiltration of the axillary glands, but several of those above the clavicle were enlarged and hard. For the purpose of diagnosis a portion of the disease was scraped away with a sharp scoop. On microscopical examination of these fragments the disease proved to be squamous-celled epithelioma, which had probably originated from the interpapillary processes of the rete. The breast was amputated shortly afterwards, and the infiltratd lymph glands were removed. The glandular tissue of the mamma was found, on microscopical examination, to be quite free from cancerous change, but the lymphatic glands were distinctly cancerous. The patient made a good recovery, but she returned three months and a half later with a recurrent ulcer the size of a florin at the outer end of the scar in the chest. This was destroyed with the thermo-cautery. Czerny points out that this condition is very different from that known as Paget's disease.[4]

Melanotic cancer of the male mamma.—The following are two cases of this condition.

1. The only details given of this case are that the man had cancer of the breast, with infiltration of the axillary glands; and that the disease followed a blow, and was of

Digitized by Google

two years' duration. On microscopical examination after removal, it proved to be fibrous alveolar cancer; both the cells and the fibrous alveoli were pigmented.

2. This patient was an Italian aged thirty-five. The disease was of one year's duration. When first seen he had a large hard fungating tumour of the right breast, the nipple being still preserved. The adjacent skin and other soft parts were extensively invaded by hard, cancerous nodules. The right clavicular and the axillary glands on both sides were infiltrated. The right upper limb was œdematous. The patient suffered much from dyspnœa. Palliative treatment was adopted. He died of asthenia three months later. At the necropsy the whole of the soft parts of the front of the right side of the chest were infiltrated by a very hard, quasi-fibrous growth of bright yellowish-green colour. The muscles of the chest, the mediastinal glands, right pleura, and diaphragm were invaded by growths of a similar nature, by direct extension. The right hydrothorax and the lung were collapsed. There were metastatic nodules of similarly coloured hard growth in the pancreas, both kidneys, and base of bladder.[5]

SUPPLEMENTARY NOTE TO A CASE OF RUPTURE OF AN AORTIC ANEURYSM INTO THE SUPERIOR VENA CAVA.[1]

BY WILLIAM EWART, M.D., F.R.C.P.,
PHYSICIAN TO ST. GEORGE'S HOSPITAL, AND TO THE BELGRAVE HOSPITAL FOR CHILDREN.

CASES of rupture of an aortic aneurysm into the superior vena cava are so uncommon and difficult of diagnosis that I may venture, even at this late date, to supplement with a few additional facts and remarks the valuable account given by Dr. Sisley in THE LANCET of June 15th, 1889, of a case which occurred under my care. A similar case was recorded by Prof. Gairdner in THE LANCET of June 22nd, 1889, and I quote his concluding observations, because they point very clearly to the physiological interest which attaches to this rare form of disease: "The respiration became decidedly noisy before death, without, however, any sense of paroxysmal or other dyspnœa. The stertor was quite as much cerebral as arising from pressure on the air-passages. The death, in fact, seems to have been greatly due to failure of the respiratory reflexes, and not to any sudden change in the condition of parts in the thorax." In connexion with my case it should be stated that, at the post-mortem examination, the superior vena cava was found to be quite patent. The area of the opening of communication between the vein and the aneurysm was little less than that of a sixpenny coin. A single crescentic flap was reflected downwards into the vein and remained somewhat stiffly in apposition with its inner wall, indicating the degree of lateral pressure which had existed within the vein after the rupture. The lungs were congested. The medulla was not, to the naked eye, abnormal. When the patient (then in bed) was first seen by me, the cyanosis of the head and neck was purplish-blue; but before his admission into the ward it had been several shades deeper, and was then described as "blackish-blue." The large veins were full; I did not at that time notice any pulsation in them. The radial pulse was very full, regular, and only slightly quicker than normal. Respiration was not impeded, noisy, or notably accelerated. Inspection, palpation, and percussion failed to detect any abnormality beyond somewhat deficient expansion of the chest; the double cardiac murmur was the only abnormal sound heard. I concluded that the pressure which was obviously bearing upon the superior vena cava, or upon both innominate veins, was most probably due to an intra-pericardial aneurysm, and that it might be relieved by copious venesection. During the performance of that operation the blood spirted with unabated force, and venous pulsation was noticed; the patient meanwhile became restless and confused, attempted to sit upright, and experienced a sudden call to micturate. With the gradual onset of stupor a few minutes later, the respiration became very noisy. At this stage the pupils were dilated. The breathing was frequent, and accompanied with a remarkably loud and long expiratory nasal stertor. Although there was but little inspiratory effort, each expiration was associated with powerful and sustained contractions of the abdominal muscles. This noisy expiratory hyperpnœa continued without material change until death. No general convulsions occurred.

Remarks.—Although the conditions present in this case were pathological, and therefore more complicated than those of a purely physiological experiment, they lend themselves fairly to physiological analysis, and they may be studied under the following headings:—

1. *Effects upon the venous circulation.*—The clinical history affords evidence that, in spite of slight occasional symptoms of pressure, the bulging of the aneurysm into the superior vena cava had been tolerated up to the time of rupture, and that the sudden onset of extreme cyanosis of the head and neck may be safely ascribed to that accident as a cause. The mechanism of production of the cyanosis is sufficiently clear. The systolic blood wave, propagated through the patent orifice of communication, told powerfully upon the column of venous blood, periodically hindering its descent into the auricle. Regurgitation of arterial blood into the tributary veins may have taken place at first, but it probably soon encountered in the venous tension an increasing resistance. Venesection had the effect of lessening the latter temporarily, and under its influence venous pulsation occurred, and probably for a while some regurgitation also.

2. *Effects upon the pulmonary blood-supply.*—The passage of arterial blood into the right auricle had no obstacle of this kind to overcome, and was favoured by the diastole of the auricle coincident with the ventricular contraction. It may therefore be assumed that, at each systole of the heart, the volume of arterial blood which penetrated into the right auricle, and subsequently underwent a second aeration in the lungs, was at least equal to the volume of venous blood which was thereby excluded from the heart. Thus the pulmonary arteries must have contained mixed blood, of less venous character, and therefore less stimulating to respiration, than normal; whilst the blood within the pulmonary veins would have possessed at least the normal arterial standard.

3. *Effects upon the medulla and its respiratory functions.*—In the medullary centres the vascular changes induced by the rupture of the aneurysm must have been (*a*) an improved supply of oxygenated blood, (*b*) an imperfect removal, and an unusually high pressure of venous blood. This combination would afford an adequate explanation for the coexistence, observed in my case, and also recorded in Prof. Gairdner's case, of intense cyanosis, and of complete freedom from active dyspnœa; the amount of oxygen having been sufficient, at least in the early stages, to counteract the stimulating effect of an excess of carbonic acid. But in addition to the chemical stimulus of the gases in the blood, the medulla was soon subjected to a progressive form of mechanical stimulation due to the increasing dilatation of its veins. It is conceivable that the expiratory hyperpnœa which was subsequently developed in my case may have resulted from this cause. In whatever way it was produced it presented a close analogy to the expiratory type of breathing which is observed in the second stage of asphyxia by tracheal occlusion, differing, however, from this in its longer duration, in the persistent supply of oxygen, and in the absence of general convulsions.

Prof. Gairdner gives prominence in the report of his case to the stertor, without, however, describing its kind. Further information as to whether the stertor was of the inspiratory or of the expiratory variety, and as to the presence or absence of any expiratory hyperpnœa, would be of much value in connexion with the subject of this communication.

In conclusion, the ultimate effects, on the respiratory function, of the forcible injection of aortic blood into the superior vena cava were clearly a depression of the inspiratory activity of the respiratory centre and a great increase in its expiratory activity. These may have been the outcome of complicated influences, such as I have suggested, exerted primarily on the medullary centre. But I suspect that the expiratory hyperpnœa was in great measure secondary to a peripheral irritation of the vagus in its bronchial and in its laryngeal distribution. As tributaries of the superior vena cava the veins of the laryngeal mucous membrane could hardly have escaped considerable blood-

pressure, and the bronchial veins were probably more exposed to pressure and to possible reflux than any other veins, owing to the fact that their parent veins (the left innominate and the vena azygos) arise near the heart, and are at their origin unguarded by valves. Severe congestion must have been occasioned in this manner within the sensitive respiratory membrane, and this alone may have sufficed to excite a sustained expiratory reflex such as I have described.

Clinically the case is of importance (1) because it shows that the mere removal of sixteen ounces of blood does not suffice to ward off the fatal consequences of the rupture; (2) because it suggests that death is probably due to the pressure of the blood within the cranium rather than to the quality of the blood; and (3) because it also shows that, in spite of the existence of some collateral circulation (which was, in my case, evidenced by the much slighter degree of the cyanosis in the upper limbs than in the head), the progressive increase of the intracranial pressure is likely to be too rapid for the establishment of a sufficient collateral relief.

Diagnosis in obscure cases, such as the present one, where the aneurysm is latent, is aided by the suddenness and intensity of the cyanosis, coupled with the relative freedom from dyspnœa. It would be greatly aided by the existence of a well-marked venous pulsation; but, judging from my experience in this case, I doubt whether pulsation will be found present in every case at the time when venous tension is at its height. If venesection should be resorted to, an arterial character of the blood flowing from the vein would be likewise almost conclusive. I am not prepared to state definitely from memory that, in this case, the colour of the blood spirting from the vein was brighter than appeared consistent with the degree of the cyanosis; such is, however, my strong impression of what occurred.

As regards *prognosis*, by far the most important quantity—namely, the size of the rupture—is incapable of being ascertained during life. The same must be said also of the next important factor—viz., the size and capabilities of the collateral channels, and especially of the communications between the vena azygos, on the one hand, and the inferior vena cava and its lumbar and renal branches on the other. In estimating the possible duration of survival these important anastomoses should not be overlooked. In cases of gradual erosion, preceded by pressure sufficient to obliterate the channel of the superior vena cava,[2] they would probably enable the circulation to be carried on. For in itself the partial reversal of the route followed by the blood does not give rise to so serious a form of contamination as that suffered by the blood in congenital cyanosis. But where the rupture is sudden and extensive, the chances of the mechanical distribution of the blood being spontaneously, or by the help of any method of treatment whatsoever, restored to and maintained in a condition of equilibrium, even approximate, must be admitted to be extremely small.

Curzon-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

CASE OF TETANUS OCCURRING TEN DAYS AFTER DELIVERY.

By HENRY PEACOCK, M.R.C.P., F.R.C.S.

M. B——, aged twenty-five, residing about three miles from Gloucester, was attended by a midwife on March 1st, 1888, the case being a primipara. The midwife sent for me after (as she said) the woman had been in labour for forty-eight hours. On arriving I found that the pains had ceased, and that the head was resting on the perineum, which was very rigid and enormously distended. I at once applied the forceps, and had little difficulty in delivering her of a large and vigorous female child. There was a slight laceration of the perineum at the fourchette, but not involving the sphincter, or of sufficient consequence to cause any particular notice. I saw her the following day, and so well did she appear that I did not consider it necessary to call again, and I left her in charge of her mother and a neighbour. On the tenth day after her confinement I was called in, and found her in the following condition: lochia and lactation natural, pulse 90, temperature 100°. I was told that she had been doing remarkably well up to the eighth day, when she complained of a little difficulty in swallowing and of stiffness about the neck. I at once diagnosed an attack of tetanus; in fact, trismus had set in, the jaws being so firmly closed that it was impossible to open the mouth without using the handle of a spoon as a lever. The muscles of the neck were thrown into agonising spasm on the slightest motion or on any attempt made to touch her; the head was thrown back (opisthotonos), and her expression exhibited the "risus sardonicus" in a remarkable degree. A turpentine enema was at first administered, and a strong chloroform and opium liniment rubbed on the neck and back. On my next visit, a few hours later, I threw up by the rectum thirty grains of the hydrate of chloral, and gave the same drug by the mouth in fifteen-grain doses every four hours. On my visit next day, I found the paroxysms somewhat less, and there was a little less difficulty in opening the mouth. My friend Mr. Cuthbert, surgeon, of Gloucester, who took a kindly interest in the case, accompanied me in my next visit, and agreed with me that the same treatment should be persevered in, although he expressed little hope of the patient's recovery. On the next day (the third from the attack), the tetanic spasms were more violent, but she was still able to take nourishment in the shape of beef-tea and milk. I injected hypodermically a quarter of a grain of morphia, and still continued the chloral every four hours. Sound sleep followed the morphia injection, and the violence of the spasms was somewhat abated and occurred less frequently. On my next visit with Mr. Cuthbert, we found her much worse, the pulse 120 and temperature 100°. On the fourth day from the attack the paroxysms were less violent, but the diaphragm and abdominal muscles were affected, and death took place the same night, evidently from exhaustion.

Now on referring to old and modern works on obstetric medicine, I cannot find any record of tetanus following delivery, and I am at a loss to account for the cause. The laceration of the perineum would naturally suggest that it was a decided case of traumatic tetanus, but as slight and even severe lacerations are so frequent in primiparæ one would look to some other cause, and as puerperal disease had been prevalent in the neighbourhood for some months previously, might not a peculiar state of the nervous system brought on by the epidemic influence predispose to the attack? or was it caused by the perineum having been so long in a distended state with such direct pressure and stretching of the cutaneous branches of the pudic nerve? Such cases are certainly very rare, for in a practice of nearly fifty years I have never witnessed one like it.

Gloucester.

ILL EFFECTS OF ANTIPYRIN.

By THOMAS WINGRAVE, M.R.C.S. Eng.

OWING to the indiscriminate way in which antipyrin is now being administered for an endless variety of diseases, I think that all cases should be recorded in which unpleasant symptoms arise from its administration. The following are brief particulars of a case now under my care.

A young lady aged twenty-one, has been under my care suffering from chronic ovaritis, associated with intense dysmenorrhœa. In addition to treatment by bromide of ammonium and tincture of gelseminum (which, by the way, were fairly successful in reducing the pain), I had given her some powders consisting of ten grains of antipyrin, one of which was to be taken when the paroxysms became severe. On July 25th last she took one of these (the first); about five minutes afterwards she experienced a very curious sense of heavy weight in the thorax, with a feeling of suffocation, her breathing became hurried and difficult, and there followed almost immediately a loss of power in the left side (the right side was slightly affected); in a few minutes a peculiar, very bright erythema appeared over the whole surface of the body, the patient appearing, as her mother said, "just like a boiled lobster." This rash was accompanied by a sensation of "pins-and-needles" down

[2] Dr. Charlewood Turner's case probably belonged to this class. See Path. Soc. Trans., vol. xxxvi., p. 148.

Digitized by Google

the left arm and leg; the circulation seemed to be arrested for a little while, as the rash faded to a dull purple. In a few minutes a feeling of collapse set in, accompanied by a profuse cold perspiration, and simultaneously severe vomiting began. In about ten minutes, under the influence of stimulants, all these unpleasant symptoms passed off, and she seemed to have recovered entirely. That the drug was good was shown by the fact that two or three other patients had had some quite recently from the same box, and I can only attribute the symptoms above described to an idiosyncrasy on the part of the patient. If such untoward attacks are to be reported frequently, it seems to me that the action of the drug should be more fully investigated experimentally than seems at present to be the case.

West-street, Finsbury-circus, E.C.

A PERFORATION OF THE SEPTUM NASI OCCURRING IN CEMENT WORKERS.

BY ALEXANDER G. R. FOULERTON,
RESIDENT ASSISTANT SURGEON TO ST. BARTHOLOMEW'S HOSPITAL, CHATHAM.

THIS perforation of the cartilaginous septum of the nose is not uncommon amongst workers in cement factories and probably in other trades in which conditions similar to those which I shall describe are prevalent. It occurs as a round opening situated a little above the columna and close to the floor of the nostril. Its size will vary, and beyond a little discharge from the ulcerating edges of the perforation no inconvenience results. Its causation is as follows. The dry cement dust is drawn into the nostrils and accumulates on the hairs in the neighbourhood. This necessitates the frequent use of the little finger in order to clear the passage out. An abrasion of the epithelium at a spot on the septum, against which the nail scrapes as the finger is rotated, becomes, on the course of events which gave rise to it being repeated, an ulcer. The ulceration is after a time followed by perforation. This lesion, which, so far as I am aware, has not been described before, is of some little practical importance, inasmuch as one would be rather apt to attribute to syphilis a perforation of this sort if no obvious cause were to be found.

CHARING-CROSS HOSPITAL.

EXTRA-UTERINE GESTATION; ABDOMINAL SECTION; PERITONITIS; DEATH; NECROPSY.

(Under the care of Mr. BELLAMY.)

DR. MATTHEWS DUNCAN,[1] in a clinical lecture on extra-uterine gestation, has passed this subject under review, and alluded to several cases under his care. He says, "In extra-uterine gestation much has yet to be done before the utility of laparotomy can be well defined. We need more knowledge of the natural progress of the disease, more knowledge of the anatomy, more experience in laparotomy?" That the literature on this subject is now very extensive is proved by reference to the medical journals of the last few months, cases being recorded in large numbers, but accounts are still valuable. As regards the frequency of extra-uterine gestation, Bandl mentions five cases out of 60,000 gynæcological and obstetrical cases under observation during a period of five years in Vienna, whilst Goodell[2] says, "Extra-uterine fœtation is by no means so rare a complication as is supposed by the majority of the profession, and is perhaps the most common cause of sudden death in women. H. F. Formad, the well-known pathologist, is one of the two coroner's physicians in Philadelphia, and he holds now in his possession nineteen specimens of extra-uterine fœtation which he has collected within four years at inquests made by him in his official capacity." We have recently published notes of two cases of extra-uterine fœtation successfully treated by abdominal section.[3] The first case was one of tubal gestation; rupture at the end of the second month; several slight hæmorrhages into the peritoneal cavity in the first half of the third month; the left Fallopian tube, which had been expanded and ruptured, was removed. The second case was one of subperitoneo-pelvic gestation. At the operation, performed at the beginning of the fifth month, a fœtus, about six inches long, was taken from a sac in the left broad ligament, the sides of the opening in the sac stitched to the abdominal wound, and the placenta left *in situ* for several days. An attempt to remove it twelve days later caused severe hæmorrhage, and the whole of it was not removed for more than three weeks. Hæmorrhage is a cause of considerable anxiety to the operator in these cases, and it will be observed that Mr. Bellamy found it necessary to plug the cavity in his patient in order to arrest it. This has led to the suggestion that, as the death of the child will in time sever the vascular connexions of the placenta and allow it to be more easily detached, the operation should be postponed until evidence of the death of the fœtus is obtained. But, although a fœtus may be carried for months or even years, the risk is too serious, from rupture of the sac, to allow the suggestion to have much weight in practice. The following is from notes by Dr. F. O. Stedman, surgical registrar.

Mrs. H——, tailoress, aged twenty-five, was admitted on April 22nd, 1889. The following was her condition on April 24th. In the centre of the abdomen, situated entirely below the umbilicus, was a swelling, which had been gradually getting larger during the last three months. On percussion, dulness began about three fingers' breadth below the umbilicus; extremities of flank resonant. In the right flank the dulness commenced at a distance of three fingers' breadth from the anterior superior spine, and commenced at about the same distance on the left side. There was no bulging in the flank. The measurements were: at the umbilicus, 25 in.; and at a point 2 in. below the umbilicus, 27·5 in. From the xiphoid cartilage to the umbilicus, 6 in.; and from the umbilicus to the symphysis pubis, 6 in. From the right anterior superior spine to the umbilicus, 6 in., and the same measurement on the left side. There was most pain on the right side of the swelling; sometimes the pain extended across the abdomen. She had not menstruated for three months, and had one child four years and a half ago. Vaginal examination showed the cervix severed and partly softened. Urine clear and straw-coloured; sp. gr. 1014, no albumen. On either side of the cervix a firm mass could be felt above. Milk could be squeezed from the breast. Dr. Watt Black in consultation examined the patient, and found a tense elastic tumour in the right side of the lower part of the abdomen, reaching to within three fingers' breadth of the umbilicus, and the uterus pushed over to the left side.

On April 25th, at 10 A.M., Mr. Bellamy operated by making a median incision, about three inches in length, below the umbilicus. On opening the peritoneum a large quantity of clot appeared, which was not quite recent, but had not become organised. On removing some of this clot a fœtus (three to four months old) appeared, and was readily removed, the umbilical cord tearing through. A mass was then removed consisting of blood-clot and apparently of placenta; there was some oozing from the pelvic region, which was temporarily stopped by putting in a large sponge. The lower part of the great omentum was infiltrated and matted together with blood-clot; it was therefore ligatured in two places, cut off, and removed. It was impossible to ascertain what was the exact situation of the ectopic gestation, but it seems to have been either in the right Fallopian tube or between the tube and the ovary. A large cavity, continuing to ooze, was plugged with three sponges, having ligatures attached to them, which were brought out of the abdominal wound. The wound was then closed at its upper part with Chinese twist, and a large sponge placed over the abdomen, which was dressed antiseptically. The pulse was regular and easily compressible (120). At

12.30, the patient having had no sleep since the operation, a hypodermic injection of morphia was administered. She died at 6.30 A.M. on April 25th.

Necropsy.—On removal of the dressing and cutting the sutures, the small intestine was found adherent to the front of the wound and the coils adherent to one another by fibrinous lymph and blood-clots. On separating the coils of intestine a large cyst was found, bounded in front by the abdominal wall and the bladder and pubes, to the right by the cæcum and adjacent structures, and to the left of the middle line by adherent coils of intestine. The cavity, which extended nearly to the right of the middle line and was in size as big as a child's head, contained a quantity of lymph and blood-clot. The intestines showed some recent and old peritonitis, but not enough to account for death, the inflammation being localised to the lower part of the abdomen. The uterus and its appendages, together with the bladder and vagina, were taken out, then the bladder was cut away and the uterus opened with scissors from the front; it contained a decidua one-third of an inch thick. The other organs were not removed. "The parts of intestine were set aside for further dissection." Permission was only obtained to examine the abdomen.

HULL ROYAL INFIRMARY.

CARIES OF VERTEBRÆ; ANGULAR CURVATURE; RECENT PARAPLEGIA; RESECTION OF LAMINÆ; RECOVERY; REMARKS.

(Under the care of Mr. HENRY THOMPSON.)

THAT there are cases of paraplegia secondary to spinal caries which may be greatly benefited by operative treatment has become a well-recognised fact, and evidence as to the good result of such interference is accumulating. The following case is a contribution to the surgery of the subject of considerable interest. The cases which Dr. Macewen published in 1888[1] are a curious commentary on the dictum of one of our text books, that "no operation such as trephining the spine is justifiable, as the compression is due to disease of the membranes, and not to displacement of the bones." Dr. Macewen says: "The first operations of the kind were undertaken by me for the relief of paraplegia due to angular curvature of the spine. In such cases pressure may be exerted on the cord, either by connective-tissue neoplasms, or by direct displacement of the bodies of the vertebræ, both lessening the lumen of the canal. By lifting the laminæ from the affected part, the tumour could be removed and relief at the same time given to the compressed cord, where the osseous walls in front were found to encroach upon the calibre of the canal." On May 9th, 1883, that surgeon removed a connective-tissue tumour and laminæ of vertebræ for paraplegia with incontinence in a boy aged nine, the subject of Pott's disease, in the dorsal region. Improvement was at once manifest, and cure soon attained. A second case, that of a girl, was operated on in the following year, and proved equally successful, although her symptoms were more severe. "A third case was also successful, but two others have not been so; one succumbed a week after the operation, the other some months later to an attack of general tuberculosis." He attaches importance to the presence of an even, regular, and continuously febrile temperature before the operation. Mr. Wright[2] reported a case in which he removed the laminæ of three vertebræ in the mid-dorsal region of a girl of seven, taking away a buff-coloured leathery substance. There was some improvement at first, both in motion and sensation, but this was not sustained. Mr. Lane, in the case referred to by Mr. Thompson in his remarks, removed the laminæ of the fourth, fifth, and sixth dorsal vertebræ in a boy of seven. Mr. Thompson's case is remarkable for the extent of the paralysis and the height at which the disease was situated, as well as for the success of the operation.

Patrick M——, aged thirteen, was admitted under the care of Mr. Thompson on Jan. 28th, 1889. In 1883 part of a rickety wall fell on him, and in consequence he was an in-patient of the infirmary for three weeks with paraplegia. This paraplegia lasted for thirteen months and then completely disappeared, leaving, however, angular curvature in the lower cervical region. During these thirteen months an abscess formed on the left side of his neck and discharged for six months, but it is not known whether or not any fragments of bone came away. So completely, however, did he recover from his paraplegia that he was able to run and jump and get into mischief like other boys, although ever since the accident he had had difficulty in passing urine. Three weeks before admission he began to complain of pain in his back, and paraplegia gradually developed. For a fortnight before admission he had complete loss of power in his legs, and they were often spasmodically drawn up. During night and day he was crying out with pain in his back and legs, and he had high temperature and night sweats. On admission the boy was thin, with an anxious expression. There was an abrupt angular curvature about the junction of the cervical and dorsal vertebræ. The arms were partially paralysed, more especially the muscles moving the shoulder joints, and the intercostal muscles were paralysed below the third or fourth interspace. Respiration was almost entirely diaphragmatic, the chest hyperæsthetic above the third rib, whilst the abdominal muscles were paralysed and the legs completely so. Sensation in the paralysed regions was delayed, but not absent. His deep reflexes were exaggerated, the superficial ones absent. He had power over the sphincters and over the bladder, but complained of much pain in urinating; urine highly alkaline. The temperature was 98·4°. In spite of all treatment he steadily went downhill, and by Feb. 12th, owing to the development of great tympanites, which interfered with his diaphragmatic respiration, he was in imminent danger; and after consultation with his colleagues, Mr. Thompson determined to try to relieve the pressure on the spinal cord, which was evidently the cause of his symptoms. Mr. Thompson, after careful consideration of the case, recognised the probability that the mischief was not confined to the immediate neighbourhood of the curvature.

On the evening of Feb. 13th the boy was brought into the theatre. He was wrapped up in blankets, had hot-water bottles placed on each side of him, and then being turned almost on to his face, and chloroform having been administered, the region of the angle was thoroughly cleansed and made as aseptic as possible with solution of perchloride of mercury. Mr. Thompson, assisted by Dr. Pigeon, made an incision along the prominent angle commencing an inch or so above its first appearance, and terminating well below its disappearance. This incision was carried well down to the bone, and then by means of a scalpel and periosteum elevator the skin, muscles, and fasciæ were separated from the bones and the laminæ exposed. He then with a fine saw and bone forceps divided the laminæ of two of the vertebræ and also separated the spinous processes of the same, and after a little trouble raised up the prominence and exposed the spinal membrane. The spines of the vertebræ first removed were supposed to be the last cervical and the first dorsal, and that of the second dorsal was afterwards removed. The dura mater at first looked compressed and did not pulsate, but in a few minutes it commenced to do so. There was no appearance of any cicatricial or inflammatory tissue, but the bodies of the affected vertebræ seemed to be very near to and to be compressing the cord. It was not thought necessary to open the sheath, so the wound was stitched up, covered over with protective, a thick layer of boracic acid powder, and upon that a layer of alembroth wool was placed. A small drainage-tube was inserted before the wound was sutured.

For some days he was very ill, although the tympanites almost immediately began to disappear; but after he had got over the shock of the operation he gradually but steadily improved. The morning after the operation the temperature was 98·4°; in the evening, 102°. On the 15th, morning, 99·8°; evening, 103°.—16th: Morning, 99·6°; evening, 100·4°.—17th: Morning, 99°; evening, 99·6°.—18th: Morning, 99°; evening, 99·4°.—19th: Evening, 100°.—20th: Evening, 99·4°. After this date it was not higher than 99°. The wound was dressed three times, and was then completely healed. His recovery was delayed by a sharp attack of bronchitis, which came on on March 14th, but he is now well in health, he can stand with one hand resting on a table, he can move his legs one before the other, can lift them up when laid on his back, and it is believed that he will completely recover. He has been regularly galvanised and shampooed, and will shortly be sent home.

Remarks by Mr. THOMPSON.—Resection of portions of the spinal column is, comparatively speaking, a new opera-

[1] British Medical Journal, vol. ii., p. 308.
[2] THE LANCET, vol. ii. 1888, p. 64 (Mirror of Hospital Practice).

Digitized by Google

tion. When done for recent injuries it has been almost universally fatal. Professor Macewen, at the Glasgow meeting, astonished his audience by the exhibition of some cases in which he had removed portions of the column for various causes, but they were chronic in character, and he lays down the axiom not to interfere in the presence of any acute symptoms. The above case shows well some of the peculiarities of the paraplegia of Pott's disease—viz., loss of power without loss of sensation. No paralysis of bladder or rectum, but painful tenesmus of the former organ. I conclude that during the process of the cure of the original curvature the spinal cord had accommodated itself to its contracted habitat, but that the advent of a certain amount of fresh hyperæmia or inflammatory mischief was sufficient to produce pressure enough to redevelop the paraplegia. In the *British Medical Journal* of April 20th, 1889, there is a very similar case recorded by Mr. W. A. Lane of Guy's Hospital, but in his case the symptoms were neither so acute nor so marked, and much more rapid improvement followed.

Notices of Books.

Archives of Surgery. By JONATHAN HUTCHINSON, LL.D., F.R.S. Vol. I., No. 1. London: J. & A. Churchill.—This is the first issue of a new journal, to which, with but very few exceptions, Mr. Hutchinson intends to be the sole contributor. The reasons for taking this rather unusual course are stated in the author's preface, and they are in the main two—the accumulation of a large amount of carefully sifted clinical material, and the inability, from want of time, to write an exhaustive treatise on surgery. This number opens with the beginning of a paper on Intestinal Obstruction, in which Mr. Hutchinson combats the teaching of some among us who recommend resort to laparotomy as soon as the diagnosis of acute intestinal obstruction has been made. He regards certainty of diagnosis as often impossible, and the possibility of cure by milder measures than laparotomy not remote. The treatment advocated is the employment of abdominal massage of a very vigorous kind and the administration of enemata. This is an excellent paper, and should be read by all, especially by those who hold that laparotomy affords the only hope of relief in cases of acute obstruction. Then follow accounts of certain rare and anomalous cases, clinical memoranda, &c. Fourteen pages are devoted to a surgical catechism for senior students in the form of questions and answers, and to short cases for diagnosis. Four good coloured illustrations complete the number. The journal is undoubtedly very interesting, and if it is maintained at the same level we anticipate for it a large circle of appreciative readers.

Beiträge zur Pathologischen Anatomie und zur Allgemeinen Pathologie. Redigirt von Dr. E. ZIEGLER und Dr. C. NAUWERCK. Vol. IV. Jena: G. Fischer. 1888–89.—The five "Hefte" which constitute the fourth volume of this recently-established journal of pathology are replete with important and interesting memoirs contributed by workers in many of the continental laboratories. Reserving for other occasions the notice of any of these writings, it may be of interest to state here the contents of this volume, indicating the universities to which the authors are attached. 1. Cosmic Evolution: being Speculations on the Origin of our Environment. By E. A. RIDSDALE, Associate of the Royal School of Mines. Pp. 130. London: H. K. Lewis. 1889.—In this little *brochure* the author endeavours to show that all bodies at present existent in the universe have, by gradual evolution or differentiation under a fixed law acting during varying conditions, been wrought from one primordial form of matter. This form, he thinks, originally existed at an exceedingly high temperature, and was endowed with far greater chemical activity than any of its numerous descendants. The evolution was attended with a gradual loss of heat, increase of density, and diminution of chemical activity. He suggests that the several planets were left behind in their orbits, during the sudden contractions of the primordial mass, as gaseous masses or rings; but if so, surely gold and hydrogen would not be found on the same planet.

All about Pasadena and its Vicinity, its Climate, Missions, Trails, and Cañons, Fruits, Flowers, and Game. By C. F. HOLDER. Pp. 141. Boston: Lee and Shepard. 1889.—This volume gives an account of Pasadena, a health-resort at the head of the San Gabriel Valley in Los Angeles County, South California. The information may be found useful by those who think of wintering, or of sending patients to winter, near the shores of the Pacific, but the author's description of its climate and the advantages to be derived from it must, we think, be taken with some amount of reservation. "It is not Paradise, as I have said; but a careful examination of the country year after year will certainly justify the statement that it possesses more in every way to make life pleasant and less to render it uncomfortable than any one spot that can be mentioned in this country or the available portions of Europe." Again, he says: "People rarely die here, so we are told; at least, they seem disposed to live on to prosperous ages. The author enjoyed the acquaintance of an old lady of San Gabriel who, it was said, was at least one hundred and seventeen years old ..... Another old lady, Señora Eulalia Perez de Guilen, died here in 1878 at the ripe old age of one hundred and forty years." We can hardly accept the "it is said" as satisfactory evidence of the ages stated. The equable temperature and the good accommodation for visitors in the hotels and large boarding-houses seem to render Pasadena an eligible winter health-resort.

The Royal Academy Pictures, 1889. London: Cassell and Co.—This tastily got-up thin quarto is issued as a supplement to the *Magazine of Art*, published by the same firm, and contains a selection of the pictures exhibited this year at Burlington House. The selection includes, among works of artists of established repute, some of real merit by men outside the charmed circle of the Academy, and these are by no means the least worthy of admiration. The volume cannot but add to the already high reputation of the enterprising publishers, and should command an extensive sale.

New Inventions.

BENNETT'S PATENT FLEXIBLE LEATHER BRUSH.

THIS simple contrivance is due to the ingenuity of Mr. F. J. Bennett, who is well known in connexion with the Geological Survey. It consists simply of a moderately stiff bristle brush of the ordinary type, about two inches broad and eight or nine inches long, set into a flexible leather back, which terminates in loops at either end, so that the whole brush is about two feet six inches long, and sufficiently flexible to fold on itself with a very moderate amount of pressure. Mr. Bennett advocates its use for dry-rubbing the skin as a means of cleansing which may be taken in addition to the ordinary bath, or as a substitute for bathing when baths are not to be got—a condition of things which many a traveller has experienced. The brush is also useful for producing mild and rapid counter-irritation, and its use is recommended for threatening lumbago and the milder catarrhal troubles to which all are liable. Liniments are often ordered more for the purpose of enforcing rubbing than for any special virtue in the liniment, and there is no doubt that Mr. Bennett's contrivance has great value, because every part of the body, such as the loins or the soles of the feet, can readily be reached by the individual himself quite as easily as with a rough towel. The flexible nature of the brush conduces to ease in packing, which is a great advantage. The brush is made by Mr. Ashdown, 35, Northbrook-street, Newbury.

DR. DETTWEILER'S POCKET FLASK FOR THE DISPOSAL OF SPUTA IN PHTHISIS.

WE have received from Messrs. Krohne and Sesemann one of the flasks mentioned by Dr. Hermann Weber in his letter addressed to us last week. From the subjoined illustrations the construction of the flasks can

readily be understood. Messrs. Krohne and Sesemann are the agents in this country for the sale of these flasks.

THE "PRESYSTOLIC" BRUIT.

To the Editors of THE LANCET.

SIRS,—Dr. Acland, in the second part of a clinical lecture published in your issue of July 27th, mentions me amongst those who have written in support of Dr. Barclay's explanation of the causation of the "presystolic" bruit as due to the reflux which must necessarily occur during the closure of a rigid mitral valve. I may, therefore, be permitted to point out the insufficiency of the argument which he adduces as controverting that interpretation of the clinical phenomenon. Dr. Acland is far from appreciating the basis of Dr. Barclay's view when he mentions as the chief argument relied upon by those who hold that view (1) that the force of the auricular systole could not produce so loud and harsh a sound as the typical "presystolic" bruit, and (2) that the absence of a break between this bruit and the systolic bruit, which so frequently accompanies it, is inconsistent with the supposition that the two portions of the continuous sound should have been produced by currents of blood going in opposite directions. These statements are, indeed, no argument in favour of Dr. Barclay's views, for (1) the fallacy of the former is proved by the fact that a prolonged mitral diastolic bruit commencing immediately after the second sound, and therefore, in part at least, caused by influx of blood into the ventricle unaided by any muscular contraction, may have the same harsh character as the short "presystolic" bruit by which it is continued up to the first sound; and (2) as regards the second statement, if it were true that continuity of a cardiac murmur is inconsistent with a reverse of the direction of the blood stream producing it, this would be fatal to Dr. Barclay's view, which implies a reversal of the direction of the blood passing through the mitral orifice between the diastolic part and short "presystolic" termination of the prolonged bruit often occupying the whole interval between the second sound and following first sound of the heart. The ventriculo-systolic explanation of the "presystolic" bruit rests (1) mainly upon the physical fact (α) that, with rigidity of the mitral curtains, there must be some, greater or less, *delay in closure* of the valve, and some *reflux of blood* in the process of closure; and (β) that this reflux, if of sufficient amount to produce a distinguishable sound, would necessarily produce a bruit with the precise characters of the "presystolic" bruit—a bruit of a rough harsh character, like the diastolic bruit often accompanying the "presystolic," because, like it, due to vibration of the rigid valvular curtains held out from the ventricular wall in the course of the blood stream, and dependent upon this position of the valvular curtains more than upon the force of the blood stream by which they are thrown into vibration, and continuous with a preceding direct diastolic bruit, like the note of a violin produced by the to and fro movement of the bow; a bruit "running up" to the snap of the valve made tense on closure, that sound being abnormally accentuated from closure taking place at a later period of ventricular systole, and a bruit differing in character from that of regurgitation after closure of an incompetent valve, owing to the arrest, partially or completely, of the vibration of the valvular curtains by contact of their edges, and the consequent predominance of the blowing sound of the fluid stream forced under high pressure through the chinks between the curtains when thus brought together. This view rests (2) upon evidence of the sufficiency of the duration of this mitral-closure reflux for the production of an audible bruit, afforded (α) by the occurrence of a "prediastolic" bruit of precisely similar character referable to semilunar-closure reflux, under conditions, in the elastic resilience of the arterial trunks, less favourable to prolongation of this interval of reflux than in the case of the muscular contraction of the ventricle; (β) by the clinical evidence of retardation of the cardiac action in states of quiescence in the subjects of mitral stenosis, in power-saving adaptation to the impediment to the passage of blood through the heart; and (3) lastly, by cardiographic tracings (by Galabin and Mahomed) which indicate an abnormally long interval between the auricular systole and apex beat.

Thus, according to the ventriculo-systolic explanation, the "presystolic" bruit is referred to an agency necessarily present, and producing valvular vibrations, which, if audible, would produce a bruit of that character, and of the sufficiency of which for the production of the bruit there is evidence in clinical observation. The weakness of the auriculo-systolic view is that there is no proof that the auricle is contracting at the time that the bruit is heard, or that the auricular and ventricular contractions do, or could, occur in such a way as to produce a bruit of the precise characters of the "presystolic" bruit—i.e., an auricular systole causing an influx of blood into the ventricle, increasing in force and volume to within an inappreciable interval from the first sound, and followed by a ventricular contraction so rapid as to arrest the auriculo-ventricular influx at its maximum, and close and make tense the rigid mitral curtains, in an inappreciable space of time. Until it is proved that a bruit of this character could be produced by the auricular systole, under some possible modifications of the auricular and ventricular contractions, the conviction of those who recognise the sufficiency for the production of this bruit of the reflux unavoidably occurring in the closure of a rigid mitral valve, cannot, I think, be affected by arguments in support of auriculo-systolic hypothesis as to its causation.

I am, Sirs, yours faithfully,

Finsbury-square, Aug. 6th, 1889. F. CHARLEWOOD TURNER.

THE LANCET.

LONDON: SATURDAY, AUGUST 17, 1889.

PROBABLY no previous case of alleged homicidal poisoning produced a greater sensation in professional and general circles than the one the subject of this notice has caused. The social and moral surroundings of the case have invested it with a glamour of extraordinary interest. Until the present we have deferred a lengthy comment, in order to obtain sufficient opportunity to consider and carefully weigh the evidence tendered at the trial, and compare the leading points raised by the prosecution and defence with the known facts of arsenical poisoning in general. It is chiefly our purpose to discuss the medical testimony, but we should be failing in our duty if we neglected to review the other incidents that together represent an engrossing forensic history.

We need hardly reiterate that two problems were left to the Liverpool jury to solve. (1) Did the late Mr. MAYBRICK succumb to the lethal effects of arsenic? and (2) that being proved, was the poison administered by his wife? To say the least, there was a powerful motive to crime, but then such motive would be inoperative unless it presented itself to a person willing and ready to seize the opportunity of perpetrating murder with malice aforethought, or to one unable from moral and intellectual weakness to resist the impulse to commit a criminal act. Taken by itself, such incentive must be received with the utmost caution, for, as Mr. Justice STEPHENS said, the greater the guilt suspected the greater is the presumption of innocence.

Now, it may be accepted without reserve that Mr. MAYBRICK was a confirmed hypochondriac, and that he had for years been in the habit of resorting to the use of drugs. Nay, further, it must be admitted that on two occasions at least he had taken arsenic medicinally: once in America, when he suffered from malarial disease; and later in this country, when he procured it from a chemist in the form of a "pick-me-up' draught. Whether he habituated himself to "arsenic eating" is matter of conjecture. Mrs. MAYBRICK more than once complained of the deceased taking powders which she appeared to think might be detrimental to his health. She did this in writing to a brother o Mr. MAYBRICK many months ago, and again verbally to the family doctor. The conclusion to be drawn from these facts is not clear. On the one hand, these complaints might be supposed to point to circumstances antecedent to, and possibly causative of, his fatal illness; and, on the other, they might equally be considered as of little value as regards the question—How did Mr. MAYBRICK come by his death?

The first issue the jury had to try was this—Was Mr. MAYBRICK'S death attributable to arsenical poisoning? Clearly on this head they had to be guided by the medical evidence, which was undoubtedly most conflicting, strange as it may appear, when it is considered that the inquiry related to a poison of definite chemical composition, of frequent employment in the past as a means to compass death, one that can with the greatest precision be detected and the amount determined by analysis, and, lastly, the symptoms which it causes being as a rule pronounced. For the prosecution it was contended that the symptoms Mr. MAYBRICK evinced were consistent with the theory of arsenical poisoning; that the post-mortem appearances were in accordance with the symptoms; and that the results of the analysis of the viscera were corroborative of the same. By the defence it was argued that certain symptoms usual in arsenical poisoning were not present; that some of those which existed were not marked with accustomed severity; and that the absence of arsenic from the stomach and vomit post mortem, and the small quantity found in the liver, supported the hypothesis that death was due to gastro-enteritis not caused by administration of the mineral. Much stress was laid upon the absence of conjunctival itching and injection. These symptoms are present without doubt as a rule, but we cannot agree that they are necessarily so, judging by the known fact that the other symptoms of poisoning by arsenic are subject to marked variation as to existence, time of onset, duration, and severity: e.g., as regards diarrhœa, in twenty-three cases collected for analysis it was *known* to have been absent in four (GUY and FERRIER); and again, "The pain in the abdomen and vomiting are occasionally not urgent, except towards the close of life, and in rare cases have been absent" (WHARTON and STILLÉ). Moreover, the arsenic, though acting primarily and mainly as an irritant, may cause other groups of symptoms—e.g., they may be chiefly those of collapse, or, again, of coma; and not only do the symptoms of each group vary amongst themselves, but those of one group may take the place of, supersede, or mask the symptoms of another group.

In Mr. MAYBRICK'S case the proximate cause of death was clearly gastro-enteritis and irritative fever. But what was the cause of the gastro-enteritis? In our opinion the defence were in error when they endeavoured to establish as two distinct and alternate hypotheses *quoad* the cause of death—gastro-enteritis and arsenical poisoning; for arsenic poisons primarily and chiefly by setting up gastro-enteritis. There is one fact mentioned in the account of the post-mortem examination that seems to us of some weight—namely, that the enteritis was very marked in places, whilst in others it was absent or less pronounced. This is more in accordance with the theory of inflammation from an irritant cause, rather than from exposure to wet and cold. The localisation of the congestion in parts distant from one another would be explained by supposing that it was produced by the process of elimination of the poison by the intestinal glands in the lower part of the small intestine and in the rectum, whilst the duodenal injection would chiefly be due to the direct action of the poison in the same way as the stomach. Except as the result of an extensive irritant, or previous organic disease, such as cancer or ulcer, fatal gastritis must be extremely rare, and, indeed, we are of opinion that the above-mentioned causes should be excluded before the assumption of so-called idiopathic gastritis as a sole cause of death should be entertained. Irritant food and drink were suggested, but no facts were elicited to support the assumption. No other person in the house or at the office

Digitized by Google

suffered in a similar way, and analyses of commercial samples, specially procured for the purpose, of the artificial food taken by Mr. MAYBRICK, gave negative results. Turning now to the results of the chemical analysis of the viscera &c., we find nothing inconsistent with the theory of arsenical poisoning in Mr. MAYBRICK's case. The total amount existing in the body post mortem was calculated at something under two grains, or in itself nearly a fatal dose; but this would probably be—especially considering that the stomach and its contents contained no arsenic—only a fractional amount of what was taken, seeing how rapidly the poison is eliminated. As proof of this assertion we quote the following statements, made at a trial, by Professor G. F. BARKER of Yale College: "It (arsenic) has been detected in the urine within one hour after it has been taken. The liver acquires its maximum quantity, in the opinion of several authorities, in from fifteen to eighteen hours after administration." "It is eliminated from the liver, and may entirely disappear in from eight to fifteen days after being taken; depending on the quantity and other circumstances." "It is not a cumulative poison." "Persons have died from the *primary* effects of arsenic in eight days, and no trace of the poison has been found in the body on analysis." Finally, on this head we must subscribe to Dr. STEVENSON's testimony of opinion. He is *facile princeps* amongst contemporary toxicologists, a man of unrivalled experience in this special department of medical science, of world-wide reputation.

Having thus arrived at the conclusion that the deceased fell a victim to arsenical poisoning, there remains for consideration the questions, Was the arsenic administered by design or taken by accident? and if by design, Was it taken by Mr. MAYBRICK himself or at the hands of his wife? The circumstantial evidence is too strong to seriously entertain the theory of accident. Mrs. MAYBRICK'S counsel adduced the following points in evidence: (1) It was shown that Mr. MAYBRICK had on more than one occasion taken arsenic as a medicine; (2) that Mrs. MAYBRICK had more than once complained of her husband dosing himself with remedies, and had particularised "a white powder" both in her letter to Mr. MICHAEL MAYBRICK, and in her explanation to the Court at Liverpool as to the manner in which the arsenic found its way into the Valentine meat extract. The symptoms of which Mr. MAYBRICK complained prior to the onset of his last illness were not such as to arouse a suspicion that he was then subject to the habit of arsenic eating; at least, on their own showing, the defence could scarcely advance such a proposition, for one of the main points on which they depended in proof of Mr. MAYBRICK'S not dying from arsenic was the absence of conjunctival irritation, and no mention was made of the existence of this symptom at any one time. Now it seems to us that this offers a direct negative to the theory of the self-administration of arsenic, at least with suicidal intent; for a man bent on such a purpose would not subject himself to protracted torture when a single dose would effect the desired end. This aspect of the question, it is true, was not presented by the defence, but we put it forward in order, by way of exclusion, to arrive at a final decision as regards the motive, means, and act that were subservient factors in the deplorable issue. Had Mr. MAYBRICK'S symptoms in the first instance been caused by the self-administration of arsenic on rational grounds, would he not have suspected that possibly his own act was in fault rather than the prescience of the doctors, which he seems to have complained of? Moreover, there is no testimony that he did not give himself up in every way to the care and directions of those whose lot it was to treat his serious illness. Look at it from whatever point we may, we are bound to face the assumption—nay, even accept it—that Mr. MAYBRICK was not cognisant of what was destroying his life. What, then, apart from motive, are the facts that tend to link Mrs. MAYBRICK'S name with the administration of the poison to her husband? Somewhere between April 15th and 25th, probably about the 20th, Mrs. MAYBRICK—openly it is true—purchased twelve fly-papers from a chemist, ostensibly because "the flies were getting troublesome in the kitchen." This reason may at once be discarded, since (1) the defence did not suggest it; (2) because at that period of the year the flies were not likely to be troublesome; (3) inasmuch as Mrs. MAYBRICK'S cook deposed to the fact that the flies were not troublesome. Mrs. MAYBRICK'S reason for her purchase as given to the chemist was obviously false, and yet for all that it did not follow that she obtained them for a criminal purpose. If she really bought them for cosmetic purposes she may have lied to shield herself against the charge of vanity. It is evident, moreover, that these papers were not put to the use for which they were intended, for they were found in a basin in Mrs. MAYBRICK'S room, soaking in water and covered by a towel—just what might be reasonably imagined if they were destined to yield a face wash. Mr. MAYBRICK'S illness dated from April 27th, when he attended the Wirrall races. On the evening of that day he complained of numbness, sickness, and pain, which he attributed, and perhaps not without some show of reason, to an overdose of medicine prescribed by Mr. FULLER of London, and dispensed by a chemist. Read by the light of the subsequent analysis—which showed that a bottle of such medicine obtained at his residence contained arsenic, whilst another bottle found at his office was free from the poison, although, as sworn, neither bottle originally contained the poison, nor was it prescribed—is there any doubt that the arsenic was introduced subsequently to the delivery of the medicine by the chemist? Here, too, had Mr. MAYBRICK intended clandestinely to administer arsenic to himself, would he not have chosen to put it in the bottle at his office rather than the one at his residence? On April 28th Dr. HUMPHREYS was called in, Mr. MAYBRICK being again sick. On April 29th he was better, having apparently recovered from the initial attack of April 27th. On this same date (the 29th) Mrs. MAYBRICK purchased twenty-four more fly-papers from another chemist—an ominous fact as it seems to us, since not more than from about ten to fifteen days previously she made her first known purchase of twelve of these papers. On April 30th Mr. MAYBRICK went to business, as also on May 1st and 2nd. On May 1st some Du Barry's revalenta food, which passed through Mrs. MAYBRICK'S hands, was sent to his office in a jug. Subsequently arsenic was found in some substance adhering to the rim of the jug, although the latter had been washed. On May 2nd some beef-tea

Digitized by Google

was sent to his office, and he was ill after taking it. On May 3rd—a notable date—he was subject to vomiting, retching, and pain. On May 4th the sickness was so severe that he could retain nothing. On May 5th he still vomited, and complained of pain in the throat—henceforth till shortly before his death an abiding and prominent symptom. On May 7th Dr. CARTER saw the patient, who complained to him of "vomiting and diarrhœa for several days." On May 9th there were tenesmus and diarrhœa. On May 10th Dr. CARTER detected arsenic in the Valentine meat juice, which the nurse had seen Mrs. MAYBRICK take into an adjoining room and then replace it in the sick chamber. Mrs. MAYBRICK'S explanation of this was that she put a powder into the meat juice at the direction of her husband, and that, having spilled some of the extract, she filled up the bottle with water—quite possibly an innocent act, but certainly one calculated to arouse suspicion, as judged by other events which succeeded. On May 11th, Mr. MAYBRICK died, and on that same day, in a linen chest, there was found a box which contained a bottle, some arsenic mixed with a dark powder, and also a handkerchief on which there was some arsenic. On the following day, May 12th, two hat boxes were discovered. In box A was a wooden box enclosing three bottles. The first of these bottles contained from twelve to fifteen grains of solid arsenic, and some charcoal; in the second was a saturated solution of arsenic, with a little solid arsenic, which had apparently separated from solution; in the third bottle there was arsenic in solution, and in the solid state. In box B was a tumbler, and in this a handkerchief containing twenty grains of arsenic. On a dressing-gown and on a handkerchief in the pocket were stains impregnated with arsenic. To all of these articles Mrs. MAYBRICK had access, and considering that she alone in the house was proved to have recently purchased arsenic—to the extent of seventy grains or more—one can scarcely convict the jury of having added "insufficient motive to insufficient facts."

We can have no desire that the Royal prerogative of mercy should not be exercised in this case, but as a duty to the living relatives of the deceased, to a painstaking, fearless, and honest jury, and to one of the greatest ornaments of the English Bench, we solemnly assert as our unbiased opinion that the verdict arrived at in Mrs. MAYBRICK'S trial was warranted by the evidence.

FROM statements made in the *Gaulois*, it would appear that continental experience leads to two very opposite opinions as to the effects of solitary confinement on the minds of prisoners subjected to the influence of its operation. From the results at Mazas, the conclusion is that solitary confinement in French prisons leads to derangement of the intellect, and more especially to melancholic depression with suicidal tendency in prisoners who were previously of good health and constitution, and who inherited no predisposition to insanity. As many as thirty-two suicides in fourteen years are stated to have taken place at Mazas, "in spite of every precaution." We are not able to judge of the nature of the precautions taken, but they do not appear to have carried with them the merit of success; and precautions against suicide are clearly more in the hands of officials than are precautions against those occult atmospheric and insanitary influences by which deaths are caused in individual cases. Belgian experience, on the other hand, seems to lead to the impression that the "solitary" prisoner gradually comes to look upon his cell as "home," and frequently takes to ornamenting it with coloured pictures in a way in which Dr. VOISIN, the Belgian authority, recognises no symptom of imbecility. Some Spartan philosophers would, we doubt not, see more greatness or at least strength of mind in the man who commits suicide under such circumstances; and they would be apt to regard the pictorial ornamentation of the miniature "home" (if the word can be used without irony in this relation) as a token rather of mental imbecility. But, be this as it may, closer inspection of the details points to a more rigid adherence to the *solitary* principle among the French than among the Belgians. The daily visits of a variety of officials among the latter serve to break the painful monotony of an entirely solitary prison life, and they establish practically what in England is called "separate confinement."

In our convict prisons separate confinement has now been carried out upon a systematic basis for about fifty years. The term at first was eighteen months; but upon "facts" of a somewhat ambiguous or imaginary nature, the public mind became apprehensive of prejudicial results upon the minds of the convicts. The timidity of the prison officials during this experimental period was recognised by the convicts themselves, and they feigned insanity, and made capital out of extemporised convulsions with such success that the period of separate confinement was reduced to nine months in the case of convicts undergoing penal servitude. Under different circumstances, prisoners undergoing shorter terms of imprisonment in local prisons have a period of two years' separate confinement. In a Memorandum on Separate Confinement in the Appendix to the Report of the Directors of Convict Prisons for 1887-88,[1] Dr. GOVER, the Medical Inspector of Prisons, demonstrates the fallacy of the public and official belief that solitary confinement in a convict prison for eighteen months had been proved to act detrimentally on the minds of prisoners. He states, and there is no better authority on the subject in this country, that "experience shows that separate confinement under present conditions is not injurious to the mental or bodily health, and that the present limits of nine months and two years in convict prisons and local prisons respectively, are arbitrary and fanciful." Again, he says, "The conditions under which the prisoner is placed are such as to warrant the assumption that separate confinement is favourable to bodily and mental health; and facts are in accordance with such an assumption, as would be evident to anyone who might inspect the whole prison population of England and Wales, and who would carefully compare the condition of prisoners on the point of completing terms of imprisonment for twelve months or two years with that of prisoners undergoing shorter sentences, or of those just admitted, and those waiting for trial..... The fact that separate confinement in a modern English prison for two years not only does not injuriously affect the mental and bodily health, but is frequently attended with benefit, affords very strong presumption that it may be continued with perfect safety for much longer periods."

[1] See THE LANCET, Dec. 8th, 1888, p. 1141.

Digitized by Google

Carrying his experience and opinion to their legitimate conclusion, Dr. GOVER does not hesitate to recommend the substitution of a limit of three years for the existing limits in convict and local prisons; the longer term permitting desirable modifications (in the way of industrial occupation as cooks, bakers, cleaners, &c., prior to release), without interference with the discipline of the prison, or any sacrifice of the principle of separate confinement. This suggestion of Dr. GOVER will have to be borne in mind in connexion with any proposed change of the law dealing with the various terms of imprisonment to be awarded to convicted offenders.

It is clearly impossible to arrive at any just or satisfactory comparison of the effects of solitary or separate confinement or, indeed, of any system of imprisonment in different countries without an equation being in the first place worked out as to the influence of the various factors which contribute, either as cause or effect, to the construction of a problem of much social and psychological interest. The following are the chief factors whose influence and bearing would have to be estimated:—1. The general national characteristics. 2. The personal idiosyncrasies of the prisoners—cast of mind, temperament, disposition—with considerations as to hereditary influences and congenital peculiarities. 3. The previous life history of the individual prisoner—as to social status, home culture, education, occupation, previous convictions, &c. 4. The discipline and treatment involved in the imprisonment. 5. The dietary in relation to physiological requirements. A comparison of the effects of penal legislation in different countries implies the existence of information on all these points; and it is not too much to hope that, in these days of international congresses, the necessary facts and statistics may be collected with a view to completing our knowledge on a most important branch of social science.

THE state of the ancient town of Rochester has long been a source of anxiety to those acquainted with its more hidden parts, and in January, 1887, we published the report of a special commission which we appointed to investigate its sanitary circumstances. We then pointed out how, for want of sewerage, the soil on which Rochester stands was in large part a sewage-laden soil; we recalled the fact that Dr. DE CHAUMONT had, at the beginning of the late European cholera epidemic, visited the town on the part of the Local Government Board, and had declared its sanitary administration to be "unsatisfactory and inefficient"; and we concluded our account of the city by expressing a hope that the "sad story" which our Commissioners had been bound to set forth might awaken a wider interest in matters which so deeply concerned its population.

This year the Local Government Board have again taken up the matter, and Mr. SPEAR has recently prepared a report on the general sanitary condition and administration of the district. From this report we gather that Rochester is still without any regular sewerage. The only semblance of drainage consists of overflows from cesspools and privy pits and a few slop drains, which empty into highway rain-water drains, or on to the river banks in small creeks, &c. But even this mischievous arrangement is only partial, for cesspools and privies with "uncontrolled leakage" generally abound; indeed, the cesspools are regarded as failing in their purpose if their contents do not get away into the soil. When they do fill up, a supplementary one is at times contrived, by means of an old disused well or otherwise. And this condition of things is made worse by reason of the confined and close back yards and courts which our Commissioners described, and which evidently remain—the houses being thickly aggregated on a soil with "accumulation of enormous quantities of sewage beneath their surface," the effluvia constantly contaminating the air breathed by the unfortunate inhabitants of these localities. But even as regards newer property, Mr. SPEAR says that the condition of things in the matter of excrement disposal is scarcely more satisfactory; and he instances, in this connexion, the state of the village of Borstal, where outbreaks of enteric fever have occurred during the past four years.

In 1887 we referred to the prevailing neglect as to filth removal, which until June, 1888, was left to owners and occupiers. And though change has taken place as to this, we regret to state that it was only under compulsion, the Local Government Board having been at last compelled to issue an Order under Section 42 of the Public Health Act. And even now there is evidently no disposition to do the work with the frequency needed in the interests of health, the task being postponed until the process of emptying is "imperatively called for by threatened overflow." Indeed, as we stated in 1887, so says Mr. SPEAR in 1889, there is only one real remedy for the state of affairs exhibited and maintained in Rochester, and that is the proper sewering of the district and the abandonment of the cesspool system. Some preliminary efforts have, it is true, been made to secure the co-operation of Chatham and Gillingham in this matter; but though these have failed, Mr. SPEAR distinctly says that no sufficient reasons have been adduced why Rochester should delay the execution of its own proper plans.

As we explained in 1887, a public water-supply is available for Rochester; but notwithstanding the fact that the chalk is made the receptacle for so large an amount of filth, there are still in Rochester some 125 local wells. How far the sanitary authority are hindered in closing these by reason of negative evidence obtained on the chemical analysis of single samples of water is by no means clear, but they have closed fifty-three wells since 1885, and this on positive chemical evidence that their contents were polluted.

One other point was referred to by our Commissioners. It was to the effect that for many of the defects of housing which had come under notice, the Artisans and Labourers' Dwellings Act, 1868, alone afforded sufficient remedy, and that there was no reason why the provisions of this Act should not be duly enforced. Mr. SPEAR, in now reporting on the medical sanitary administration of Rochester, points out that no formal representations have yet been made to the authority under the Act, nor, indeed, any of importance as to houses unfit for habitation.

In conclusion, we would remark that a day of reckoning can hardly fail to be in store for Rochester and its inhabitants. We have distinctly appealed to the latter to make such exhibition of public feeling as must necessarily have its influence on the action and composition of the sanitary authority. But, so far as we can learn, matters remain much the same as in 1887, and this although the

Digitized by Google

Public Health Act enables even a single person to make definite complaint as to default in such matters as the want of sewerage, as would of itself necessitate formal inquiry by the central authority into the alleged default, and, if need be, the adoption of compulsory measures. How far the intervention of the County Council can be expected to make up for this dangerous state of apathy remains to be seen.

Annotations.

"Ne quid nimis."

SIR GUYER HUNTER AND THE COUNCIL OF INDIA BILL.

SIR GUYER HUNTER deserves the thanks of the people of India for taking advantage of the Council of India Bill, now before Parliament, to press the appointment of a medical man on the Council. The questions of sanitation and vital statistics which arise in connexion with Indian government are of the first importance, affecting not India alone or England alone, but Europe and Asia too. It is amazing that such an appointment has never been made since the creation of the Council of India in 1858, though the medical services abound in men who would add the strength of armies to the Council. We thank Sir Guyer Hunter in the name of the profession, and heartily wish his proposal success.

THE NOTIFICATION OF INFECTIOUS DISEASES BILL.

IT was neither to be expected nor desired that so significant a measure as the Notification of Infectious Diseases Bill should pass without criticism. We publish to-day a letter from Dr. W. J. Collins, which expresses in a very able way the best objections that can be made to the Bill. He follows the line taken in *The Times* by Mr. Crofts, secretary to the Liberty and Property Defence League. Mr. Crofts says the measure will tell most hardly on the poor, especially the small tradesmen and the working man. The small shopkeeper, Mr. Crofts thinks, will be under terrible temptation to keep infectious diseases to himself, and to avoid calling in the doctor. The Bill is simply the latest "instrument of coercion devised by medical officers of health and their confederates in Parliament." Dr. Collins' criticism is wider, and deals with certain medical points which no doubt deserve consideration, and which Dr. Collins thinks have not received the amount of attention they deserve. Medicine, he reminds us, is not an exact science. Diagnosis is not always easy; sometimes it is impossible. Then who shall decide what diseases are infectious? A Lumleian lecturer has, he says, been endeavouring all his life to get proof of the infectiousness of scarlet fever, and has failed to find it, but has obtained some evidence to the contrary. Then questions of humanity arise, and it will be asked whether the well should not make way for the sick, rather than the sick be removed to save those who are well. Finally, "medical men will not be willing to risk their friendly relations with patients for thirty pieces of—copper"; though, by the way, we are sorry to see that one of our medical contemporaries is quoted by another writer opposed to notification as saying that a numerous section of the profession will notify to earn the fee of half-a-crown, unless they can earn sixpence more to pretend not to recognise an infectious case, in which event they will be slow to recognise what is wrong with the patient. Against our contemporary's estimate of the influence of an extra sixpence, or of a whole half-crown, in influencing the conduct or the diagnosis of any number of medical men, we enter our emphatic protest. Though Dr. Collins' points are much more entitled to consideration, they do not alter our view that the State has a right, in the interests of the many, to insist on notification. No medical man need be inexact in this matter. If he is not clear in his own mind, he is not required to take action till he is so. The cases of difficult diagnosis are the exception, and one of the advantages of delay in legislation, of which there is a good prospect, is that it will give the profession time to demand some protection not afforded in the Bill against punishment or troublesome proceedings for honest mistakes. Dr. John Harley's opinion on the non-infectiousness of scarlet fever has happily not yet infected anybody else that we know. That notification does not work uniformly well may be admitted. Does anything human do so? Does the lifeboat or the fire brigade always save life? Do they not sometimes involve the loss even of more life? The highest note in Dr. Collins' letter is that notification, involving isolation and possibly removal of the sick, is not a magnanimous policy. Fear of infection, he would have us believe, is a low motive. But suppose that it is to the interest of the sick themselves to remove them? This is the general opinion of the sick and the friends of the sick, as is proved by the wide acceptance of the Metropolitan Asylums Hospitals for infectious cases. It is not a low motive for a parent with a case of scarlet fever or diphtheria in the house to regard the safety of his other children, and on this ground to accept public accommodation and advantages which would otherwise be unreasonable. There is infinite pitifulness in the multiplication of disease in straitened homes, and the notification system will save more shopkeepers than it will ruin. The case of puerperal fever is a more difficult question. It does not tend to spread in a household, and it is much less easily defined than the other diseases mentioned. The medical members of the House should seek to delete this from the list of notifiable diseases. With this omission and the acceptance of the single notification, we cannot see any sound argument against the Notification Bill, though we are not altogether sorry to see indications that it will not be passed this session.

THE COLLEGE OF SURGEONS' LIBRARY.

THE August number of the *Library* contains an interesting account of the origin and growth of the College of Surgeons' Library, by Mr. J. B. Bailey. From the time of their separation from the Barbers in 1745 the Surgeons' Corporation showed no great appetite for professional literature till the year 1800. The ancient manuscripts of their craft had remained in the hands of the Barbers' Company, and had by them been sold to Mr. Whiston, the bookseller. Hardly any attempt had been made to fill their place. In 1800, however, stimulated by a new charter, a change of residence, and the possession of Hunter's Museum, the College authorities remembered their need and voted £50 towards the formation of a book-room. For a time the new project advanced slowly. There was no librarian, and the books were difficult of access. The period 1827–29 was a memorable one. In it no less than £5269 was expended on books, and in 1829 the first librarian, Dr. Willis, was appointed. In 1833 there arose a governing committee. In 1835–36, when the College was practically rebuilt, the library was not forgotten, and the 18,000 volumes which it contained were provided for by building the present reading-room and the librarian's room. Successive additions have since been made which afford house room for 40,000 volumes. The first catalogue, one of authors only, was issued in 1831. This was enlarged by four supplements between 1840 and 1860. Since the latter date no printed index has appeared, but a complete list of all books in the library, with author and subjects, arranged in a common alphabetical order, is now in course of pre-

Digitized by Google

paration by Mr. Bailey himself. The library includes, besides the more recent works, such literary curiosities as the first edition of Celsus (1478), the first of Hippocrates (1500), of Galen (1526), the rare Aselli "De Lactibus," with coloured woodcuts (1627), and others. It may safely be said, therefore, that if the College of Surgeons during the latter half of the last century appeared as a very Philistine in its disregard of books, it has in our own era proved itself as true a believer in their value.

CERTIFICATES OF DEATH.

So much has been written and said recently as to the giving and refusal of certificates of the cause of death that it is desirable, in the interests both of medical practitioners and the public, to examine the question closely in all its bearings. Many practitioners are under the impression that they have no option in the matter, that they are bound to give a certificate in the case of every person whom they have attended in his or her last illness, and the wording of the Act which relates to this (37 and 38 Victoria, 1874, chap. 88, sec. 20, sub-sec. 2) would imply such construction. It runs thus: "In case of the death of any person who has been attended during his last illness by a registered medical practitioner, that practitioner shall sign and give to some person required by this Act to give information concerning the death, a certificate stating to the best of his knowledge and belief the cause of death, and such person shall, upon giving information concerning the death, or giving notice of the death, deliver that certificate to the registrar, and the cause of death as stated in that certificate shall be entered in the register, together with the name of the certifying medical practitioner." It would appear, reading the above according to the plain meaning of English words, that not only *must* the medical practitioner give a certificate, but also that the registrar *must* enter the cause of death in the register as it is given in the certificate. But it is well known that registrars are under no such compulsion. On the contrary, their instructions are to refer every doubtful certificate to the coroner. It is extremely unfortunate that the subsection of Clause 20, quoted above, was drawn up in its present form. Ever since the original Act (of which this is an amendment) was passed in 1837, it has been generally understood that the mere giving of a certificate implied that the death was a natural one, and that all was regular; while, on the other hand, the refusal of a certificate was understood to indicate that it was a case for further inquiry. This feeling still prevails, for recently one coroner's jury censured a medical practitioner for not giving a certificate in a case which proved to be one of death from natural causes; while in another case the medical attendant was severely censured for giving certificates stating natural causes of death in what subsequently proved to be clear cases of arsenical poisoning. In the Maybrick case the coroner's inquest was held in consequence of no certificate of the cause of death being forthcoming. It would be easy to give examples of casés where a certificate either could not be given at all, or only at the risk of causing great mischief or unnecessary delay to an inquiry. Fortunately there is an escape from the difficulty, since one clause of an Act of Parliament must be read with the other clauses. And the penalty clause of this Act (39) runs thus: "And every person who refuses or fails, *without reasonable excuse*, to give or send any certificate in accordance with the provisions of the said Acts shall be liable," &c. The fact that the death arose from injury, or was sudden, or accompanied by other circumstances demanding inquiry, would, it is certain, be deemed reasonable excuse for refusing a certificate; hence timid practitioners may take courage, provided they do not pass beyond the bounds of reason. It must also be observed that the Act distinctly refers to cases attended by a medical practitioner during the "last illness." Hence it should not be considered as applying to cases where a practitioner has been hastily called in within a few hours of the death. The powers wielded by the profession in giving or withholding certificates of death are enormous for good or evil, and must not be weakened on the one hand or abused on the other.

MESMERIC OR HYSTERICAL ANÆSTHESIA.

THE famous experiments performed many years ago by Dr. Esdaile, in which that well-known surgeon operated on Hindoos during what was called mesmeric sleep, are now being repeated, and with, it is said, a successful result. The latest news we have of an operation under the mesmeric trance is from Paris, where, in the Hôtel Dieu, a young woman is stated to have been subjected by Dr. Mesnet to a painful cutting operation "of the class called dangerous and requiring great delicacy of manipulation," she being at the time "wholly insensible to pain, showing no sign of suffering, and awakening," not from an anæsthetic of the ordinary kind, but from a mesmeric sleep, "wholly oblivious to what had taken place." We want the full particulars of this operation before any satisfactory expression can be offered in respect to it; but we may say at once that similar results have often been reported with little after effect in the advancement of the supposed practice of anæsthesia by mesmerism. The phenomena are exceptional. They are usually observed in persons of hysterical type, and, offering, for the moment, the greatest hopes, are quashed quickly by the miserable failures with which they are attended so soon as the mesmeric plan is applied to patients at large. The fact is that anæsthesia differs according to constitution, not largely, but in some instances exceptionally, to a degree little understood by the public generally. There is a form of hysterical anæsthesia just as there is of hysterical hyperæsthesia, and when the representatives of the first class come under the hands of the mesmerist they are such perfect specimens for his suasion that they give him the most triumphant returns. These cases call for a special study in regard to anæsthesia, since until they are elucidated there can be no sound progress. We would give an earnest warning on this matter of mesmeric hypnotism, assuring our readers that they must not expect more from it than exceptional results, and these due, not to true anæsthesia, but to individual peculiarity.

ACTION AGAINST MR. J. G. LOCK OF TENBY.

AT the Glamorganshire Assizes, at Swansea, before Mr. Justice Field and a special jury, Benjamin Griffiths, livery-stable keeper, Tenby, sued Mr. Lock, practising at Tenby, for £2000 damages for slander and false imprisonment. The slander consisted in a statement that the plaintiff was insane and should be placed under proper control. Mr. Lock has practised in Tenby for twenty years, and used to attend the family of the plaintiff till 1884, when the latter became jealous and suspicious of Mr. Lock, and objected to his professional attendance on his wife, charging him with undue familiarities &c. This feeling took an insane form. The plaintiff, amongst other delusions, described a closet in his garden, which adjoined Mr. Lock's garden, and in the floor of this closet a hole through which a man's hand appeared, which he believed to be Mr. Lock's hand, with a letter in it, though his own witnesses thought it impossible for a man's hand to be passed through the hole. Police-sergeant Carr testified to being called to the plaintiff's house several times by the neighbours on account of disturbances, and that the plaintiff's own brother requested him to lock him up. He threatened repeatedly to shoot Mr. Lock. On all essential points the witnesses on both sides were

Digitized by Google

agreed. Mr. Lock swore that there was absolutely no foundation for Griffiths' statements about familiarities with his wife, her having a miscarriage, &c. Dr. Hearder, superintendent of the Joint Counties Asylum at Carmarthen, then produced his notes on the first examination of the plaintiff, which showed him to be suffering from mania, delusions, &c., and dangerous to his wife, Mr. Lock, and others. Thereupon the foreman of the jury handed up a paper to the judge, intimating that they did not desire to hear any further evidence for the defence. His lordship intimated that the jury had found the plaintiff was a person of unsound mind who should have been under proper control. His lordship further expressed his inability to understand how anyone who had heard the trial could arrive at any other opinion. It is hardly necessary to congratulate Mr. Lock on a conclusion so natural and obvious. We would rather condole with him at the annoyance which he has had to bear, extending over years, and culminating in this trial. Considering the number of patients "cranky" and on the "borderland," as one of the plaintiff's witnesses expressed it, it is perhaps inevitable that medical men should occasionally be the victims of such an ordeal.

ESTIMATION OF OXYGEN DISSOLVED IN WATER.

SIR HENRY ROSCOE and Mr. LUNT have made an important communication to the Chemical Society on Schützenberger's process for the estimation of oxygen dissolved in water. They find that a series of estimations made on the same sample of London tap water gives results which differ 35 per cent. from the mean value, and that the time taken in titrating has a great influence, much higher results being obtained if titration be quickly than if it be slowly performed. The disturbing influence has been traced to the fact that when aerated water is introduced into an atmosphere of hydrogen, as in the usual process, it immediately begins to lose oxygen by diffusion, a fact hitherto overlooked. The result of an oxygen estimation thus depends on the degree of exposure to hydrogen during titration, and results between 0·53 and 7·56 were obtained with the same water by varying the exposure. Under favourable circumstances 20 per cent. of the dissolved oxygen diffuses, whilst in the usual form of the apparatus 50 per cent. of the oxygen diffuses during the estimation. An exposure of three minutes is sufficient to permit all the dissolved oxygen to escape. This explains the return of the blue colour during an estimation carried out in the usual manner, the *diffused* oxygen becoming reabsorbed by the reduced indigo-carmine. No return of the blue colour takes place on reducing indigo-carmine when free oxygen is absent, and the action has been proved to be due to the supernatant gas, and not to any action occurring within the liquid, as Schützenberger supposed. Diffusion also explains the observation made by Schützenberger, that twice the quantity of oxygen is found when a large amount of reduced indigo-carmine is present. In that case the dissolved oxygen is at once acted on, and so cannot diffuse. Ramsay and Williams, who have investigated the process, do not obtain twice the amount, but only an increase in the ratio 3 : 5. Diffusion also explains this observation, a smaller vessel having been used in their experiments; a larger proportion of the oxygen was found in the usual process—in other words, three-fifths of the whole. The method adopted to eliminate this error, due to diffusion, is to run the aerated water beneath the surface of a liquid containing a measured excess of hyposulphite, and a little reduced indigo-carmine as an indicator. In this way the dissolved oxygen is immediately acted on by the hyposulphite, and its diffusion prevented. For the standardisation of the hyposulphite, the two methods hitherto used were found inaccurate, the copper method being fundamentally wrong, owing to a secondary action which occurs between sulphite and dissolved oxygen; the aerated distilled water method, hitherto used with Bunsen's absorption coefficients, the authors show to be inaccurate, giving the values obtained by them, which agree closely with observations made by Dittmar. The new method of carrying out the process, and the corrected values for the oxygen dissolved by distilled water, give results for which perfect accuracy cannot be guaranteed, but which are not far removed from the truth, and certainly valuable. The reaction is much disturbed by the presence of free acid or alkali.

A MEDICO-LEGAL SOCIETY.

IN New York there is a Medico-Legal Society, presided over by Mr. Clark Bell, in which the professions of law and medicine are equally represented, and there lies before us a circular lately issued, from which we learn that the Society, having recently held an International Congress of Medical Jurisprudence, which has been successful "beyond the most sanguine expectations," proposes to improve the plan so as to make the Congress permanent in its character, and in the broadest sense international. The President was empowered and directed by the Congress to promote this idea by appointing additional vice-presidents for the various States, territories, provinces, and countries, and already a preliminary list has been prepared and published, in which the names of twenty-four gentlemen, including several chief justices and judges, in company with members of the profession of medicine, are enrolled. The design is ambitious, and, if the time be ripe for its accomplishment, its success will be exceptionally great. The question is whether the time has come. At present all the laws relating to medico-legal theory and practice are so widely different in different countries that it would at first sight seem impossible to bring them into anything like a common system. At the same time the fundamental principles must surely be nearly the same, and the objects must certainly be the same in all civilised nations. It is feasible, therefore, that by a series of friendly and learned meetings of medical and legal authorities some general code might in time be evolved. The grand difficulty that will lie immediately in the way is that of language. So long as men of different nationalities have no alternative, on meeting together for the discussion of principles, except to converse and discuss either in a different tongue or in an imperfect interpretation, so long will there be insurmountable obstacles to a common agreement, since upon nice and refined points of expression so much depends. Men not only speak in different tongues but think in them; and though they might generally understand each other for all ordinary intercommunication, it will be long before the genius of exposition of different languages and thoughts will be common property. Of course this objection does not hold good between this country and the present home of the new International, and it would be opportune, perhaps, now, for those members of the profession here, who some years ago did such active service as "The Medical Defence Association," to reconsider the idea advanced by their President, of transforming that Association into a medico-legal society for England, and so establish an English centre for the assistance and support of the wider scheme. An English and American society might at once become international in so far as the two countries are concerned, and others could be left to follow in due course, as each country founded, in imitation, its own organisation. We see, and our numerous readers will see, that a good medico-legal society centred in London would at once have sufficient work before it. Suppose, for instance, at this time the council of such a society, composed of able and well-accredited men, were available as reference in the

Digitized by Google

Maybrick case. What a load of responsibility could at once be removed from the administration. There would be a tribunal ready at once to take up any question submitted to it, and to give, after due investigation, a decision which in a matter of science would issue actually as from a court of appeal. This illustration in favour of the organisation is suggested at the present moment, because of the current interest which is being taken in a particular case. But there are other developments for action to which a medico-legal society might devote itself. The laws relating to public health would come, in the most legitimate manner, under its consideration, and lead the way to the long-expected and deserved appointment of a Minister of Health and Medical Jurisprudence. These are anticipations. The primary crux is—Can the two professions of law and medicine in this country combine for a common object and for the common good?

A PLAN FOR RELIEF OF WHOOPING-COUGH SPASM.

DR. NAEGELI publishes in the *Correspondenzblätter für Schweizer Aerzte*, a paper on whooping-cough, in which he pays particular attention to the convulsive attack of choking, describing the latter as follows: Spasm of the glottis makes every inspiration impossible, tonic convulsions of all laryngeal muscles follow, all muscles of the throat and at last those of the face also share in the attack. Trismus almost always is present during the acme of the convulsion, although the tongue generally protrudes. As soon as it is possible to open the rima glottidis again so far as to admit of sufficient air for respiration, all sensation of choking and congestion of the blood with their sequelæ disappear as by a miracle. Heiberg was the first to observe that the raising of the upper jaw is the best method of making the larynx admit air, and he recommended a plan for that purpose, which Kappeler had mentioned before him, and which Naegeli has modified and described as follows: Standing in front of the child, the nurse lays firm hold with the index and middle finger of the ascending ramus of the lower jaw in ront of the ear, places both thumbs against the chin, and by strong but gentle traction and pressure moves the lower jaw forwards and downwards. If the mouth is a little open the jaw may be fixed by placing the thumb or index finger alone behind the anterior lower incisors and grasping the chin with the rest of the hand, performing traction as above. In all these cases the left hand rests on the forehead of the patient and performs counter-traction. If the nurse is behind the patient, she may place both thumbs close above the angle of the jaw, the index on the zygomatic arch, and the rest of the fingers on the chin, pushing forwards and downwards. Immediately the upper jaw is raised the child must be told to draw a deep breath. The plan may be adopted even if the fit comes on during sleep, and Naegeli says that if so the child does not wake.

BELGIAN MEDICAL ETHICS.

A CODE of medical ethics which is published in a recent number of the *Scalpel* is very similar to the rules, written and unwritten, which are generally understood as governing right-minded medical men in this country. One or two matters, however, may be mentioned wherein there is some slight difference. A medical man, on being summoned to a new patient, is bound to do his best to ascertain whether anyone else has been in attendance during the existing illness, and the mere denial of the patient is not to be considered as entirely absolving the doctor from any further attempts to get at the truth, as patients frequently say they are newly come to the neighbourhood or equivocate in some way when questioned as to any previous attendance. If it is found that some one else has been in attendance during the existing illness, the successor is bound to satisfy himself that his fees have been paid before he accepts the position of medical attendant himself. Again, when acting as temporary substitute for a *confrère*, if a new patient hitherto unknown to the latter sends, the locum tenens may retain him permanently on his own list, a permission which we think would scarcely be recognised in this country. This code is signed by Dr. Bax, and does not seem to be in any way authoritative; nevertheless, if faithfully carried out both in the letter and in the spirit, it would certainly obviate a very large amount of friction.

THE SALFORD INFECTIOUS HOSPITAL QUESTION.

THIS question has now reached an acute stage. At the last meeting of the Town Council, Mr. D. Sharrocks, who has all along been an active opponent of the Ladywell site, moved an amendment to the effect that its purchase should be postponed until a committee had been appointed and had reported on the whole question. This was seconded by Mr. Alderman Bailey, who held that Monsall Hospital and the Pendlebury Hospital for Sick Children would answer the purposes of Salford. On the motion being carried by a small majority, the mayor, as chairman of the Health Committee, and several other members of that committee, immediately tendered their resignations. Whilst we cannot help sympathising with those who apprehend that their properties will be depreciated in value by the purchase of the Ladywell site, we cannot agree with those who would thrust the two alternatives on the Town Council. Even if the Pendlebury authorities consented to "add a wing" to their hospital for the reception of a larger number of infectious cases in children, we cannot think that, on a site which must be regarded as limited at least for such purposes as recreation, such a course would be desirable in the interests of the large body of the sick who are received into this general hospital. And, as regards the use of Monsall, the authorities of which are at any time prepared to receive into their wards small-pox patients from sanitary districts including about a million of population, we feel convinced that Salford would not be justified in its selection as a place to which people suffering under other diseases than small-pox could at any time be compulsorily sent. Salford has for many years known the value of an infectious hospital of its own, and those responsible for the public health of this populous borough can hardly be prepared to make themselves dependent merely on other institutions in other sanitary districts.

"HEREDITARY CHOREA."

ORDINARY CHOREA is sometimes hereditary, but the disease called "hereditary chorea" is in many respects different from the chorea of children. The distinction between these forms of motor perturbation and motor debility—for there can be no perturbation without debility—rests not upon any remarkable difference in the appearance and character of the movements, but rather upon other characteristics, and chiefly on the time of life at which the diseases become prevalent, and upon their observed progress. Child chorea ever tends to get better, even though it relapses; whereas hereditary chorea, once established, never ceases to exist, even though it exacerbate and remit with longer or shorter intervals. Hereditary chorea is frequently, child chorea is rarely, attended with marked mental chorea, if such a phrase may be allowed to signify the jerky, weak, intellectual and moral actions of the sufferers. Child chorea is a failure in the motor nervous machinery largely due to a disability of development. Hereditary chorea is a breaking down of a motor mechanism which had already

Digitized by Google

ceased to develop. Probably a close likeness in pathology exists between hereditary ataxia and hereditary chorea, the difference between the diseases being merely one of situation of the pathological lesion. In either case we must assume that the structures lesion of which caused the disease were defective *ab initio*. How else can we understand diseases like these two hereditary kinds, and like Duchenne's disease? The nerve functions are clearly weak, from an original and inherent fault of development, because so many members of the same family suffer, and so many generations of the same family. What especial circumstance in the history of the family protoplasm first caused the muscles or the nerves to be particularly vulnerable has never been clearly brought out. In one family of sufferers from hereditary chorea, in which no previous cases could be traced, though the means for tracing were favourable, the father had suffered from general debility, with cold hands and feet and low spirits, all his lifetime—a general want of vitality in the nervous system; such fathers or mothers may be more prone to generate a nervous system conspicuous for its capacity or tendency to degenerate long before the usual period for general corporeal degeneration has set in.

MEDICAL CONGRESS AT PADUA.

YEAR by year professional gatherings abroad are becoming more cosmopolitan in their attendance as their subject-matter appeals to a more widely diffused correspondence of scientific interests. The medical man, *en touriste*, may add another pleasure to his holiday by spending a day or two at these réunions, where German or Swiss are often found in friendly discussion with Austrian or Russian, and all four nationalities hospitably entertained by hosts either French or Italian. Foreign travel is so universal nowadays that the practitioner can never be sure when or where he may not be called in attendance on patients of diverse nationalities, or in consultation with physicians or surgeons who have qualified in other schools than his own. It is no light matter to be prepared for such contingencies, and therefore, we repeat, the opportunities afforded by international congresses of becoming familiarised with the language and *modus operandi* of foreign contemporaries are well worth embracing and turning to account. Italy frankly acknowledges she has gained much by these opportunities, and shows her sense of it by the welcome she accords to the guests she so freely invites to all her professional gatherings. The Medico-Psychological Congress, which will meet, as already announced, at Novara from the 8th to the 14th of September, will be followed by the purely Medical Congress, which is to assemble also in the Alta Italia from the 22nd to the 27th of the same month. Padua, the special seat of this latter, has many claims on the interest of the British medical man—if only as the school where so many compatriots, including the illustrious Harvey, acquired or perfected their theoretical or practical knowledge. The great consultant, Dr. De Giovanni, member of the Superior Council of Public Instruction and Professor of Clinical Medicine in the Padua School, is to preside; while the vice-presidents will be the Cavaliere Bassini and the Cavaliere D'Ancona, clinicians whose merits are acknowledged far beyond the Italian frontier. Dr. Achille Breda, Professor of Dermo-Syphilopathy, and Dr. Luzzatto, Professor of "the Propædeutic of Clinical Medicine"—subjects, by the way, more commonly represented in continental than in British seats of learning—will be the secretaries; and the two lecturers on Pathology, Drs. Alessio and Borgherini, the vice-secretaries. From all parts of Italy, and even from the countries of central Europe, physicians of eminence have already signified to the "Comitato Padovano dell' Associazione Medica" their intention to assist at the proceedings, and others who have not yet done so are invited to address the above-named committee to the same effect. An exposition containing all the latest adjuncts, mechanical and other, to the physician's art, will be on view, Public Health being the section in which the most numerous and most striking novelties will be exhibited. The surpassing interest of the fine old Venetian University town would suffice of itself to reward the physician on his holiday in paying it a visit. How much greater the attraction when he will have for his guides the hospitable men of light and leading of the locality, who are at this moment employed, as their circular sets forth, in preparing for a Congress which shall be worthy of the glorious traditions of the School of Morgagni?

THE PROPHYLAXIS OF TUBERCULOSIS.

THE New York Board of Health has not lost any time in taking action on the report recently submitted to it on the contagiousness of tuberculous diseases, for it has circulated widely the following rules to be observed for the prevention of consumption, which may be compared with those circulated by M. Chauveau's committee (*vide* THE LANCET, Aug. 10th, p. 282). 1. The sputa of suspected consumptives should be received in earthen or glass dishes containing a solution of bichloride of mercury, 1 to 1000. 2. Do not sleep in a room occupied by a person suspected of having consumption. The living rooms of a consumptive patient should have as little furniture as practicable. Hangings should be completely avoided. The use of carpets, rugs, &c., ought always to be avoided. 3. Do not fail to wash thoroughly the eating utensils of a person suspected of having consumption as soon after eating as possible, using boiling water for the purpose. 4. Do not mingle the unwashed clothing of consumptive patients with similar clothing of other persons. 5. Do not fail to catch the bowel discharges of consumptive patients with diarrhœa in a vessel containing corrosive sublimate (1 part) and water (1000 parts). 6. Do not fail to consult the family physician regarding the social relations of persons suffering from suspected consumption. 7. Do not permit mothers suspected of having consumption to nurse their offspring. 8. Household pets (animals or birds) are quite susceptible to tuberculosis; therefore do not expose them to persons affected with consumption; also do not keep, but destroy at once, all household pets suspected of having consumption, otherwise they may give it to human beings. 9. Do not fail to thoroughly cleanse the floors, walls, and ceilings of the living and sleeping rooms of persons suffering from consumption at least once in two weeks. Ten thousand copies of these rules are to be printed for distribution.

CLINICAL INSTRUCTION IN INFECTIOUS DISEASES IN GLASGOW.

IT has been amply shown before the General Medical Council that the great bulk of medical students receive almost absolutely no clinical instruction in infectious cases, which constitute so serious an element in ordinary general practice. With the general adoption of a notification system, ignorance of the clinical features of such diseases will be increasingly damaging to practitioners, and familiarity with them and with the notes by which they may be early and securely diagnosed increasingly advantageous. There are two obstacles to the general establishment and success of such teaching—a certain disinclination in students to run the risk of infection in taking such a course of clinical instruction, and the absence in the curriculum of most of our examining bodies of any requirement of such teaching. This great defect in medical education is engaging the serious attention of the Committee of Education of the Medical Council, and with other kindred matters

Digitized by Google

is to be the subject of report at the next meeting of the Council. Meantime the discredit of sending out men as "qualified to practise" who have not had any such instruction rests with the individual examining bodies and with the medical schools. There is at least one place where an earnest attempt to give real instruction in such cases is being made. We refer to Glasgow, where Dr. James W. Allan, Physician Superintendent of the City of Glasgow Fever Hospital, Belvidere, has since 1884 been most laudably engaged in such an attempt. With varying but on the whole fair success he has overcome difficulties, admitting special obligations to Professor Gairdner, his old teacher; to Dr. R. Thomson, lately senior assistant physician at Belvidere; and to Dr. Russell, medical officer of health of Glasgow, of whom he speaks as having almost obliterated typhus from the Belvidere clinique and from Glasgow, in his effective co-operation with the Health Committee of the Town Council, who have also willingly accorded the use of the fever hospital for purposes of clinical instruction. Anyone in doubt as to the importance or feasibility of such teaching should read three short (very short) addresses on this subject by Dr. Allan, reprinted from the *Glasgow Medical Journal*, and published by Alex. Macdougall, 81, Buchanan-street. Dr. Allan had three pupils only in 1884, in 1888 seventeen, and in 1889 forty. In his parting words this year he expresses himself well satisfied with his pupils and their labours. He states that he is not aware of a single case in which a student has contracted infectious disease by visiting Belvidere. Since this statement was made he has been told that one of his students did contract scarlet fever. But the statement remains a very satisfactory and encouraging one, though, as Dr. Allan argues, the risk of infection is one of the risks of the medical life to be accepted by everyone worthy of the calling, though one apparently to be considerably reduced by care and due precautions.

CONGESTED STATE OF THE PROFESSION IN PARIS.

AN Edinburgh contemporary, alluding to the suicide of a medical man, sixty years of age, owing to inability to pay his rent, quotes the *Concours Médical* as saying that in the central parts of Paris there is one medical man for every eight houses, and from another medical journal takes the following quatrain—

> Le médecin, savant et sans intrigue,
> A Paris meurt de faim,
> Ou, s'il arrive enfin,
> Savant ou non, il meurt de fatigue.

Our contemporary alleges that in Paris the ordinary explanations of a congested profession here will not hold—viz., rival examining bodies and hospital abuse. Is he quite sure that there is no hospital abuse in Paris? Certainly we do not feel so. Neither are we disposed to moralise too much on the basis of one unhappy act.

INCUBATION PERIOD OF MEASLES.

M. H. LEROUX (*La France Médicale*, No. 89) relates cases of measles in which it was fairly evident that the usual period of incubation (twelve to fourteen days) had been exceeded. In one case a child, aged seven years, who was sent into the country the day following the appearance of the rash on his sister, developed the rash himself twenty days later. In another a school-girl, whilst suffering from an attack of scarlatina was also incubating measles. For the scarlatina developed on March 29th; the fever declined on April 10th; but on the 14th she again complained of sore-throat, had coryza &c., and on the 15th showed measles rash. She had been separated from her schoolfellows for nineteen days, and either the measles had an incubation period of at least this duration or it must have been conveyed to her whilst suffering from scarlet fever. The third case was one of a boy of eight years who had been isolated from a younger sister suffering from measles, and who did not exhibit the rash himself until twenty days afterwards. Of course in each case the contagion might have been conveyed by a third person, but M. Leroux is perfectly satisfied that this did not take place. The second case is remarkable as an instance of concurrence of two specific infective disorders.

INTERNATIONAL HONOUR TO VON PETTENKOFER.

THE Royal Society of Hygiene in Italy, which has its centre in Milan, has resolved to associate itself with the congratulations accorded by his countrymen to Max von Pettenkofer on his having attained his seventieth birthday. Accordingly, it has transmitted to the distinguished Munich hygienist a richly and tastefully illuminated parchment, emblazoned with the arms of the two Royal houses of Bavaria and Italy, under whose protection the public health of the two nations respectively stands. Below this are the insignia of the Italian Hygienic Society, held aloft by two finely-executed young genii, standing on a basement on which is recorded the device: "Salus populi suprema lex esto." Then follows the address, which may be thus translated: "Most Honoured Sir,—Although men of your distinction find their most genuine recognition in the approbation with which their work is received, yet this recognition assumes its most impressive form when many voices combine in one, and the praise of individuals is blended in the universal encomium, which takes opportune expression on some memorable stage of the life journey. Therefore it is that we votaries of the science which you, more than any other, have advanced on the highway of practical observation and felicitous experiment, most willingly accede to the invitation of the Royal Italian Hygienic Society and combine our congratulations with those which your compatriots have accorded you on the occasion of your happy completion of your seventieth birthday. In these congratulations, may it be your pleasure to recognise the expression of our homage as well as of our deepest affection—feelings inextricably interwoven in our minds and hearts." To this address, peculiarly effective in the Italian original, are appended the signatures of the most prominent professors and practitioners of State medicine throughout the Italian peninsula, including many occupants of chairs in the Universities, from Turin to Naples, members of the "Scuola di Applicazione degli Ingegneri di Bologna" (School of Applied Engineering in Bologna), of the "Scuola di Perfezionamento d'Igiene Pubblica in Roma" (School of the Higher Public Hygiene in Rome), and representatives of many undertakings, private as well as under Government, for the improvement of the public health of Italy.

LEICESTER PROVIDENT DISPENSARY.

WE have on more than one occasion during the past two years referred to the dissatisfaction which has arisen at Leicester in the working of the Provident Dispensary there, which numerically is one of the largest in the kingdom, and has been hitherto fairly successful financially. Stormy meetings have from time to time been held, and the dispute has at last resulted in the malcontents starting a new dispensary called "The People's Dispensary," which has set itself to work vigorously to compete with the older organisation. The payments are to be the same as in the latter, and there is to be no tax on cards or fines for arrears of payment, and all present members of the old dispensary can enter the new one without entrance fee. Medicines

Digitized by Google

will be supplied from various druggists throughout the town, and it is calculated that 90 per cent. of the receipts will go to the medical staff and dispensing chemists. In addition, the members are to have a voice in the management of the new concern.

THE CONSERVATIVE TREATMENT OF DENTAL PULPS.

WHILST some deny that the dental pulp serves any purpose in adult life, there are many facts which seem to support the contrary view. In a healthy person, if caries of a tooth takes place, the formative activity of the pulp may be aroused and new dentine be deposited on the surface nearest the encroaching disease, and thus form a barrier, perhaps only temporary, but still a barrier to its further progress. After destruction of the pulp, certain pathological conditions—absorption and deposition of cementum—frequently occur in the root, and clinical observation shows that a tooth without a pulp has, to use an old simile, one leg in the grave. How far a nerve that is exposed can be successfully treated is an interesting question. Depending as it does not only on the local condition but upon the general health, we find the most varied views expressed, one dental surgeon maintaining that he "caps" always, another that "capping" results sooner or later in trouble, and therefore destroys the pulp at once; but probably the best practice is to treat the individual case on its merits. Should a healthy nerve be wounded accidentally during excavation, most are agreed that if it be capped the tooth will be little the worse for the complication; and it is rather to exposure from caries that we refer. The operation of "capping" a nerve as commonly practised consists in first reducing all inflammation by the removal of irritating material from the carious cavity and repeated antiseptic dressings, and then covering the exposed surface with a mixture of carbolic acid or oil of cloves and oxide of zinc, and over this a small quantity of oxy-phosphate of zinc (white stopping), mixed very thin, is allowed to flow; when this has set, the carious cavity is filled. The number of substances used for the purpose of capping is large—collodion, egg-shell, sticking-plaster, cork, &c.,—the important points being that it shall be non-irritating, that there shall be no pressure on the pulp and no space between it and the cap. In an American contemporary, Dr. Parramore recommends, after three years' experience in a large number of cases, sterilised sponge as a nerve-cap, and he opines that the sponge "becomes the seat of deposition of secondary dentine." Whether this is so or not it is at present impossible to say, as of course in the successful cases no tooth post-mortem has been made; but at any rate it is worth a trial in the interests of conservative dentistry.

DEFAULT AS TO SEWERAGE AT IDLE.

A PUBLIC INQUIRY has been held at Idle in Yorkshire, by Col. W. M. Ducat, into a complaint that the Local Board of Idle had made default in not providing the district with proper sewers; Mr. S. Wright, solicitor, appearing for his wife, who was the complainant under the Public Health Act. Mr. R. Honeyburne, the medical officer of health, was called, and he frankly admitted that no provision for the proper sewerage of the district had been provided. In the face of this evidence the clerk to the local board offered no opposition, but stated that, in deferring action, his authority had acted on his advice, and that he, in giving it, had been influenced by the consideration of cost. He, however, appealed to the inspector to urge the Local Government Board to give the authority a reasonable period, since he believed that the local board were ready, owing to outside pressure, to call in an engineer with a view of carrying out the necessary works.

THE TREATMENT OF ECZEMA.

DR. UNNA of Hamburg publishes in the *Monatsschrift für Dermatologie* a paper on the Diagnosis, Etiology, and Treatment of Eczema. He says that even before the experimental cultivation of bacilli exact clinical observation had distinguished a number of entirely different types of eczema, and he thinks that each different type will be found to require a different mode of treatment. The type most frequently seen in Hamburg is seborrhœic eczema, and the parasite causing it is the same which in the first instance produces pityriasis capitis. Those persons who suffer from seborrhœic eczema of the head, including those affected with pityriasis capitis, are apt to suffer from the same kind of eczema on other parts of the skin. Dr. Unna has repeatedly pointed out that we possess a series of valuable remedies for the treatment of seborrhœic eczema in all its forms—viz., sulphur, resorcin, chrysarobin, and pyrogallol. Of these remedies resorcin is the best, as being the least likely to produce local or general ill effects. It may also be used in an alcoholic or watery solution or in the form of ointment, paste, soap, or powder. Dr. Unna's favourite formula is a solution of three drachms of finely-powdered resorcin with an equal quantity of glycerine in six ounces of spirits of wine, diluted with four times the quantity of water or camomile tea. A thin layer of cotton wool well moistened with the solution is applied, covered with some waterproof material, and fastened by a bandage. These applications are particularly useful when the treatment is prolonged, or when it is carried out by night. They are, of course, impossible in general eczema of adults, but not in that of infants. Dr. Unna describes an especially important effect following the application of resorcin,—viz., a swelling of the epidermis, by which all painful fissures are healed in a single night. In order to ensure healing, he advises that the skin should be anointed after the removal of the bandage, and that washing with soap should be avoided. A few people suffer from a resorcin idiosyncrasy which necessitates the immediate cessation of this treatment, and the application of powder to the affected parts. This idiosyncrasy is, however, very rare, as he has only met with it ten times in five years' observation, during which time he has seen 2000 cases. He remarks that his treatment is not adapted to those cases of long-existing eczema, in which strongly-infiltrated or thickly-indurated patches occur.

PATHOLOGY OF PAINLESS WHITLOW.

DR. THIRIAR of Brussels publishes in *La Clinique* some notes of a case of painless whitlow, or the so-called Morvan's disease, which he thinks tend to prove that the central nervous system must be affected in this somewhat rare and ill-understood condition. Only one post-mortem examination seems to have been at all fully reported of a case of this character, and that was of one of Dr. Morvan's own patients (*Gazette des Hôpitaux*, April 30th, 1889). Here there were both peripheral and central nervous lesions, the cervical enlargement of the cord and the nerves of the upper extremities being affected. In the nerves there was a hyperplasia of connective tissue, and in the cord an abnormal development of interstitial tissue occupying the posterior column, the posterior cornua, and probably the central grey matter. It was unfortunately not possible to ascertain whether there existed morbid tubular cavities near the central portions of the cord—the form of lesion styled syringo-myelia—which Dr. Thiriar believes to be the condition to which painless whitlow is due. His patient was a woman of sixty-six, who six years previously had had a severe bruise on the left thumb, which caused a great deal of swelling, which swelling had never entirely disappeared. Fourteen months before her admission the first

Digitized by Google

two phalanges of the ring finger of the right hand became swollen and painful, ultimately opening and giving exit to some pus. A year later the left thumb again became painful and increased in size, and after a time broke and gave vent to some pus. Since that time there had been very little pain from either of the whitlows. On examination the lymphatic glands on both sides of the neck and in both axillæ were found to be inflamed, and the upper arms were both considerably atrophied and wanting in sensibility. There was no pain or tenderness in the neighbourhood of either of the whitlows. The theory proposed by Dr. Thiriar to account for the second whitlow, which came on without any apparent cause, is that the old injury to the left thumb, which was never cured, set up an ascending neuritis which was followed by syringo-myelia, and probably then by descending neuritis on the right side.

THE MEDICAL OFFICERSHIP OF HEALTH FOR LEEDS.

MR. GOLDIE having resigned his position as medical officer of health for Leeds, the Town Council have decided to advertise for a new officer at a salary of £700 a year. Some discussion took place as to whether the remuneration should not be on a higher scale; but in the end the amount named was fixed on, one member of the Council stating that there was no need to assume that it would be the ultimate amount to be reached by an efficient officer. We regret that a salary so inadequate to the requirements of Leeds has been, so far, decided on. We learn that Dr. Henry Tomkins of Leicester is a candidate for the vacant post, for which his large experience in public health matters eminently fits him.

THOMSEN'S DISEASE (MYOTONY).

THE *Medicinisch-Chirurgische Rundschau* translates an interesting article by Dr. P. I. Wising in the Swedish journal *Hygiea* on myotony. The affection was first described in 1876 by Dr. Thomsen of Kappeln (Schleswig), after he himself and several members of his family had been affected. The first of these cases of tonic convulsions of the voluntary muscles observed in Sweden is the thirty-third of all hitherto published. The majority of them have occurred in Germany, where army surgeons have paid special attention to this affection. Pontoppidan of Copenhagen also observed several cases. The first Swedish case occurred in a Stockholm student aged eighteen, whose whole family was entirely free from the disease, showing that heredity cannot always be the cause, as was supposed from a study of the cases in Thomsen's family, though it is undoubtedly an occasional cause, as Pontoppidan relates the case of a family in which seven members were affected, and Bernhardt also reports a similar case. Wising, however, points out that in eighteen of the thirty-three published cases it has been proved that myotonic symptoms appeared in early infancy, while in most of the others a strong suspicion exists of a similar history. Diseases of the mind in those families affected with myotony, as observed by Thomsen, seem to be exceptional; and a sudden shock, such as is mentioned as an etiological factor in some patients, probably only makes the already existing affection plainer. Wising's patient suffered as long as he could remember, and no psychopathic complication existed in his family. The essential symptoms of Thomsen's disease are a continuation of the contraction of muscles after the intention to move them has ceased, a state which Seeligmüller calls "Intentionskrampf"; this abnormal continuation, however, ceases when the intentional movement is several times repeated. The myotony in Wising's patient affected nearly all the muscles of the body, especially those of the extremities, throat, and face, and was most marked on opening the eyes. It also affected the muscles of the tongue and mastication, but the pharyngeal and eye muscles were not involved. The affection was less marked when the patient was in good spirits or had taken a little wine, also when the air was of moderate temperature, but it was worse in very warm and oppressive weather. Muscular hypertrophy, which Seeligmüller first mentioned as a prominent symptom in myotony, was in Wising's patient very pronounced, and affected all muscles, especially the deltoids, femoral muscles, and gastrocnemii. On moderate as well as strong mechanical or electric irritation of the muscles the contraction was slow without being weak, and the cessation of contraction (decontraction), even with the interrupted current, took place very slowly. This specific form of contraction on increased irritation is analogous to the beginning of voluntary movement, another point of resemblance being the slower and less persistent contraction on continued irritation. Dr. Wising considers the affection to be of a permanent character but without any effect on the duration of life; he thinks, however, gymnastic exercises, which Thomsen had already recommended, very useful.

LOCAL TREATMENT OF DIPHTHERIA.

PROCEEDING upon the view that diphtheria is primarily a local disease, the importance of early detachment of false membrane from the tonsils and pharynx is being again strenuously insisted on. Dr. Gaucher is a firm advocate for this measure, the advantage of which has recently been insisted on by Dr. de Cresantignes (*La France Médicale*, Nos. 90 *et seq.*). It is important, however, to detach the membrane with great care so as to avoid excoriation and injury. This may be done by employing a "brush" formed by absorbent wool placed over the end of a rod, and this again covered by a layer of thick dry flannel. The latter adheres to the false membrane, which it can detach without risk of particles being set free in the mouth; and a fresh "brush" should be employed on each attempt. This is followed up by the application of strong carbolic acid (10 parts) and camphor (30 parts) solution, which is of course highly caustic, but which, Dr. de Cresantignes states, is well borne. He remarks that Roux and Verson, as well as Chantemesse and Vidal, have shown that carbolic acid and camphor are the best preparations to prevent the development of Klebs' bacillus. He considers irrigations as quite ineffectual for detaching membrane of recent formation, but they are most useful in cleansing the naso-oral passages.

LICHEN.

DR. HALLOPEAU (*L'Union Médicale*, No. 95) holds that no definition yet given of lichen implies a clearly-defined morbid condition; the papular form is not distinctive, and it is impossible to ally the "pilo-sebaceous" lesions of the affection termed by Hebra and Kaposi lichen scrofulosorum with that of lichen planus, which is met with on the palms of the hands and buccal mucous membrane. His criticism leads him to these conclusions: 1. The group "lichen" is artificial. 2. There are arbitrarily included in it different affections which have in common only the papular appearance of their elements. 3. Terms derived from pathological anatomy and physiology should be substituted for the word lichen. 4. The diseases at present confounded under this name may be collected under other types, with the exception of that described by Wilson, which alone should be called lichen, for it constitutes a morbid entity. 5. The qualification of lichen planus is merely applicable to a variety of this disease. An acute and a chronic form should be recognised, and under the latter such varieties may be discriminated as lichen planus,

Digitized by Google

obtusus, acuminatus, tuberous, horny, coralliform, and sclerous. 6. The acute form comprises some of the cases published under the head of lichen ruber acuminatus.

IMPORTANCE OF EXAMINING SPUTA FOR BACILLI.

DR. HAUSMAN of Meran, in a communication to the *Med.-Chir. Rundschau*, insists on the necessity of examining sputa for the tubercle bacilli of Koch in all cases in which the diagnosis is at all doubtful. He mentions the following interesting case from his own practice as an example of this necessity. Years ago a man who had been given up came under his care in a state of emaciation and high fever, and suffering from diarrhœa. The middle lobe of the right lung and the upper lobe of the left lung down to below the level of the nipple were infiltrated and partly softened. The sputum, which was nummular, sank in water, and its quantity was immense. Over a year ago a testis had been removed for tumour and abscesses. The man had been sent to Meran for general tuberculosis, and the symptoms were so evident that a most unfavourable prognosis had to be made; indeed, the disease had begun to attack the vertebræ and the meninges. The patient could not bear to be touched, or to move his body, and seemed *in extremis*. Just at this time Koch had published his views on the subject of tubercle bacilli, and Dr. Hausman commenced a thorough examination of the secretion, believing that this undoubtedly specific sputum would quite accustom him to the microscopic appearance of tubercle bacilli. But neither he nor Koch's own pupils found the least trace of bacilli, though they repeated the examination frequently. The patient who until then had avoided any allusion to syphilis, admitted the possibility of the latter being the cause of his illness. Later on, slight osseous enlargements were observed, and as there continued to be entire absence of tubercle bacilli, syphilis was diagnosed, and the correctness of this view of the case was confirmed by the brilliant result of anti-syphilitic treatment. The patient not only did not die, but in spite of the serious lung defect and frequent relapses of a clearly syphilitic origin, he remained free from fever, diarrhœa, and from any serious amount of pain. Such signal success would have been impossible without examination for tubercle bacilli, and the patient would certainly have died. Indeed it was doubtful whether there was any real need for the operation of castration which had been performed.

VACCINATION AT EASTBOURNE.

IT is stated that the guardians of Eastbourne, having to face a growing unpopularity to vaccination, which has culminated in only 157 vaccinations out of 439 births during a period of six months, have decided to seek the advice of the Local Government Board. It is difficult to understand what advice that Board can give to the guardians, seeing that it is the latter, and not the former, who have the statutory duty of enforcing the law.

EXCRETION OF PHOSPHATES IN RICKETS.

DR. V. TEDESCHI of Trieste publishes in the *Rivista Veneta di Scienza Mediche* the following results of his examination of the urine, fæces, and sweat of rachitic patients compared with those of healthy people. In the urine of healthy children the phosphates varied in quantity even though the diet remained unchanged, the maximum and minimum amount of phosphates generally following one another directly. The urine of rickety children showed the same variation. This variation was probably the cause of different results in different examinations. As a rule, however, the phosphates in the urine of rachitic children were greater than in healthy children. The phosphates in the fæces were increased when the child was constipated, and diminished in diarrhœa. The fæces in the diarrhœa of rickety children contained less phosphates than those in the diarrhœa of non-rickety children, except the latter happened to be suffering from intestinal catarrh. Whenever the phosphates were increased in the fæces of rachitic children the same increase took place in the urine, and the same may be said of the decrease. The best remedy for the treatment of diarrhœa in rachitis seemed to be phosphate of lime. The profuse secretion of the sweat glands in rachitis contained more saline matter than is usually to be found in the secretion of healthy children.

THE INHALATION OF OXYGEN.

IN a paper on the Therapeutic Value of Oxygen Inhalation, Dr. W. Gilman Thompson (*Boston Medical and Surgical Journal*, No. 4) related experiments which showed that animals could live comfortably in an atmosphere of oxygen until a pressure exceeding three atmospheres was reached; above that pressure various effects were noted, especially a marked decrease in temperature of warm-blooded animals. Experiments were also made for the relief of dyspnœa artificially induced, with the conclusion that inhalation of oxygen does afford relief in some types of dyspnœa. Therapeutically, oxygen was used for the cure of certain general diseases, especially of the blood and circulation, and as a palliative in dyspnœa. He stated that about 200,000 or 300,000 gallons were used annually in New York. His own experience was adverse to its employment in anæmia, nor had its use in cardiac disease been encouraging. In certain cases of subjective dyspnœa it gave relief, and he mentioned a case of poisoning by coal-gas, where its administration was kept up for three days without any effect on the rate of breathing or cyanosis. It is in certain cases of asthma and of anæmic dyspnœa that its chief value seems to rest.

COMPRESSION OF PULMONARY ARTERY IN THE COURSE OF ACUTE PNEUMONIA.

DR. E. TORDIEU (*Journal de Médecine*, No. 14) records the case of a child five years of age admitted into hospital for well-marked acute lobar pneumonia of the left upper lobe, who presented a loud systolic murmur in the second left interspace, and traceable towards the axilla. The bruit persisted when the patient was discharged, but so also did the dulness and bronchial breathing at the left apex. The notion of congenital narrowing of the pulmonary artery was unsupported by any collateal evidence; and it was shown that similar bruits have been described which were subsequently proved to have been due to pressure upon the pulmonary artery by enlarged glands or phthisical consolidation. It was therefore surmised that a like causation explained the bruit in this case—a notion which was borne out by the fact that the bruit completely disappeared later, when a soft hæmic apex murmur alone was audible.

IRRIGATION IN SUPPURATIVE PERITONITIS.

DR. BERGSTRÖM reports in *Duodecim* the case of a little girl of five years of age who, some months after an attack of diphtheria, suffered from an attack of peritonitis. Just before she was seen for the first time a spontaneous opening had occurred, and a quantity of fetid matter had come away. Dr. Bergström introduced an indiarubber tube into the opening, and washed out the peritoneal cavity with a 2 per cent. solution of boracic acid at the temperature of the body. As the distance at which the child lived was great, it was arranged that the father should repeat the irrigation frequently. Opium was prescribed and enemata

Digitized by Google

ordered every third day. After two days the discharge ceased to be fetid, and the child seemed better. At the end of ten weeks the tube, which had repeatedly been shortened, was removed altogether, and the little patient made a good recovery.

H.R.H. THE PRINCE OF WALES.

HIS ROYAL HIGHNESS THE PRINCE OF WALES has been suffering from a gouty affection of the leg, which has necessitated rest, and which has incapacitated him from riding, and therefore prevented him from attending the review at Aldershot on Wednesday, Aug. 7th. His Royal Highness has much improved, and it is fully expected that the treatment at Homburg, where he now is, will greatly benefit him.

NITROGENOUS CONTENTS OF SPUTUM.

DR. M. PANOFF has examined the sputum of patients suffering from various forms of lung disease with the view of ascertaining the amount of nitrogen expectorated. The details of his results are given in No. 2 of the St. Petersburg Dissertations for the session 1888–89. The estimations, which of course included both the liquid and precipitated portions of the sputum, were made by means of the Kjeldahl-Borodin process, the general result being that the greatest daily expectoration of nitrogen was 1·14 gramme, and that the sputum which contained the largest amount of nitrogen, both when reckoned by the total daily expectoration as well as by its percentage composition, was that of phthisical patients, while, on the other hand, that which contained the least nitrogen, both absolute and relative, was that occurring in cases of bronchitis and croupous pneumonia.

FOREIGN UNIVERSITY INTELLIGENCE.

Amsterdam.—Professor Korteweg of Groningen has been appointed to the Professorship of Surgery.

Berlin.—Dr. A. König has been promoted to the rank of Extraordinary Professor of Physics. Dr. von den Steinen has qualified as *privat-docent* in Pyschological Medicine.

Breslau. — Professor Loewig, the Nestor of German chemists, in consequence of his advanced age, is about to cease lecturing. Dr. C. Alexander has qualified as *privat-docent* in Medicine.

Christiania.—Dr. Max von Frey, Assistant in the Leipsic Physiological Institute, has been offered the Professorship of Physiology.

Klausenburg.—Dr. K. Lechner has been appointed Professor of Psychological Medicine.

Lille.—Dr. Lemoine has been appointed to the Professorship of Therapeutics.

Modena.—Dr. P. Bertacchini has qualified as *privat-docent* in Pathology, and Dr. S. Cecchini as *privat-docent* in Operative Medicine.

Prague.—Notwithstanding the refusal of the Austrian Minister of Education to appoint Dr. Krauss to the chair of Clinical Medicine, though his was the only name presented by the Professorial Senate, the Senate has now presented his name again, but added to it those of Professor Fleischer of Erlangen, Prof. v. Jaksch of Graz, and Dr. Singer of Prague.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following eminent foreign medical men are announced:—Dr. A. Nuhn, Honorary Professor of Anatomy in Heidelberg; Dr. Kandinski of St. Petersburg, a well-known writer on mental disease.

DR. FARQUHARSON, M.P. for West Aberdeenshire, has paired with Sir Trevor Lawrence, Bart., M.P. for Reigate, Surrey, for the remainder of the session.

AT a meeting of the Health Committee of the Nottingham Town Council last week, Dr. Whitelegge, medical officer of health for the borough, presented a report with reference to the outbreak of scarlet fever in Nottingham, from which it appeared that the epidemic was being effectually coped with. There were then eighty-seven cases of scarlet fever in the Woodborough-road Hospital, as against ninety-eight in the previous week. The committee gave orders for fifty additional bedsteads to be procured, and it was intimated that, in the event of the scarlet fever cases increasing, the fever wing of the new Hospital for Infectious Diseases at Bagthorpe would in all probability be at once utilised.

AT an inquest held last Saturday on the body of a young woman found in the Thames at Wapping Stairs, Mr. Russell Talbot, in giving his evidence, complained that the local mortuary was merely a shed, with neither gas nor water in it, and no convenience whatever for holding post-mortem examinations. In this particular instance he had to conduct his examination in the open air, and during it the wall surrounding the place was crowded with boys. The windows of the houses about there also commanded a view of the place.

THE death is announced of Surgeon-Major James Adolphus Smith, which took place on the 3rd inst. at Bhamo, Upper Burmah, of intermittent fever, at the age of forty-one. He became a surgeon in the army in 1874, and served in the North-West Frontier of India campaign of 1876, in the course of which he was wounded, and also in the Egyptian expedition of 1882 and the Soudan expedition of 1884–5, for the former of which he received the medal and bronze star, and for the latter the clasp. He was promoted to the rank of surgeon-major in 1886.

GERMAN medical journals report the outbreak of a serious epidemic of typhoid fever at Essen. It is stated that some of the medical men have as many as fifty cases under their care. The cause is supposed to be the unhealthy condition of the ground.

THE BRITISH MEDICAL ASSOCIATION.

THE fifty-seventh annual meeting of the British Medical Association opened at Leeds on Tuesday, the 13th inst. The attendance has been exceptionally large. At the first general meeting, under the presidency of Professor W. T. Gairdner, the Annual Report of the Council was read, which referred to the present position of the Association and the work carried on by its committees during the past year. It was pointed out that when the Association first visited Leeds in 1843, the members numbered a little over 1600; in 1869, when it met again in that city, they were 4095; whilst on the present occasion the roll has reached to more than 12,000 members, and the balance of the assets over the liabilities to £35,617. The adoption of the report was moved by Dr. Holman, treasurer of the Association, seconded by Mr. C. J. Wright; and several reports of committees were presented. Mr. Rivington moved, and it was unanimously resolved, that in the opinion of those present the Members of the Royal College of Surgeons of England should have a voice in the management of the College and in the election of its Council. A vote of thanks was then awarded to Professor Gairdner, for his services during the past year, who, in replying, introduced to the meeting the new President, Mr. C. G. Wheelhouse.

Digitized by Google

In the afternoon a special service was held in the parish church, when the Bishop of Ripon preached to a crowded congregation.

At the evening meeting Mr. Wheelhouse delivered his presidential address, an abridged report of which will be found elsewhere. A vote of thanks was passed to Mr. Wheelhouse on the motion of Professor Gairdner, seconded by Dr. Cummings.

On Wednesday the Sections met in the class-rooms of the Mechanics' Institute and School of Science during the morning; and in the afternoon the second general meeting was held in the Coliseum, when Dr. Hughlings Jackson delivered the address on Medicine. At its close a vote of thanks was passed to Dr. Jackson, on the motion of Dr. Eddison, seconded by Dr. Bristowe. The interesting ceremony of presenting the Stewart prize to Dr. Klein, for his researches upon micro-organisms, and especially for his work upon the etiology of scarlet fever, then took place; the President of the Council, Dr. Bridgwater, making the presentation, and mentioning the foundation of the prize by the late Dr. A. P. Stewart.

Afterwards there was a reception at the Yorkshire College by the President, Council, and Senate, and in the evening a conversazione was given by the President of the Association and the Local Examining Committee in the municipal buildings.

THE SECTIONS.

PUBLIC MEDICINE.

The proceedings of this Section were opened by the President, Dr. E. BALLARD, who introduced the subject of "Medical Officers of Health; their Training, and the conditions on which they should hold office." He said it was clear that public interest had been roused with regard to this question, and that an expression of opinion was required regarding the relations between County and District Councils and their respective sanitary officers on the one hand, and between the latter and the sanitary authority of the kingdom on the other hand. The first question was, What are the requisites for a good and efficient medical officer of health? He thought his range of knowledge would need to be very wide, and that he ought to be able to say, "*Nihil mundanum a me alienum puto.*" Meteorology, geology, sewer and water engineering, the construction of houses, the ventilation of public and private buildings, bacteriology, and the diseases of the lower animals, all had an importance for him. Secondly, he requires practical training, comparable to what hospital work is to the physician. Some work under a medical officer of health should form part of the curriculum. Thirdly, tact was most important, as without it all other qualifications would fail of success. Young medical men whose zeal often led them astray, must remember that they are advisers, not administrators. They must allow for difficulties which seem small to them, but are great in the eyes of others. They must bear with the infirmities of their weaker and less intellectual brethren. They should keep their consciences clear by acting to the best of their ability, and look to the gradual improvement in public opinion to secure their ends. In the midst of difficulties they should seek consolation in scientific work. Nature is never unkind to such as seek her close acquaintance; she never disappoints, never vexes, never discourages. To the medical officer of health working in the wildest rural district, as well as to him who labours in the crowded town, she holds an open gate, and says: "Treasure is here; my servants are contented and happy; come and dig."

Dr. LITTLEJOHN (Edinburgh), after complimenting the President on his admirable address, and emphasising his remarks upon the importance of tact in the discharge of the duties of a medical officer of health, went on to say that he thought there were strong objections to the medical officer of health combining the duties of public analyst. The chemistry of adulterations was making such rapid advances, and the delicacy of chemical analysis was becoming so great, that it was impossible for an active officer of health to attend to such duties efficiently. He was much pleased that it was now impossible in Scotland for any local authority to dismiss the medical officer of health without the sanction of the Local Government Board. He thought there should be an absolute rule forbidding medical officers of health from engaging in private practice.

Mr. G. H. DE'ATH (Buckingham) thought that medical officers of health should have fixity of tenure while they did their duty. He thought the Local Government Board should—as is done in the case of vaccination work—periodically inspect medical officers of health and their district, and see that they do their duty and use their power and influence to make local authorities carry out what is required of them by law.

Dr. WHITELEGGE (Nottingham) held that the medical officer of health was responsible solely for the advice he gave the sanitary authority, not for the actions of the latter. He had, or should have, the advantage of the help of professed experts in law, engineering, and analytical chemistry; but, without necessarily claiming to be called a lawyer, or engineer, or chemist, it was essential that he should have a competent knowledge of the branches of those sciences which bear directly upon public-health work. As to tenure of office, the most unsatisfactory form of all was that which required re-election every year or every few years. The medical officer of health already had to obtain and classify returns of births and deaths, and the only difficulty in constituting him the official registrar was the fact that other less fitting duties are at present attached to this office. The medical officers of County Councils had a wide, though at present undefined, field of work; but although the County Councils would to some extent take over the duties of the Local Government Board, it would be a matter of regret if the supervision of the latter authority over the whole kingdom were relaxed.

Dr. BRINDLEY JAMES (London) thought that every medical officer of health ought to be apprenticed to a properly authorised officer of health to gain the experience necessary for that office. He should not practise, but give all his time to the duties of his office. He should be well qualified in every branch of medical science and the applied sciences. He should receive a proper salary to ensure his independence.

Mr. HOLDER (Hull) spoke as a member of a corporation as well as a member of the Association. He strongly approved of a period of pupilage first under a general practitioner, and then under a medical officer of health. He pointed out how in Hull the services given by Sir H. Cooper, Dr. R. King, and other medical men to the council of the corporation had guided public opinion into a wise channel, and he urged that the members of the profession would do more service to public medicine and to the public by seeking such positions where their technical knowledge would be readily and gratefully accepted.

Dr. OGILVIE EWART thought it most important that medical officers of health should first be general practitioners, in order to acquire tact in dealing with all classes. He himself had been trained as a civil engineer, but he attached very little importance to this special training compared with the experience he had acquired as a general practitioner.

Dr. CALDWELL SMITH was of opinion that the Medical Council, instead of requiring six months' attendance at a laboratory for medical officers of health, should insist upon a course of hygiene before the candidate entered for his examinations. He also drew attention to the fact that in Scotland medical officers of health had attained a certain amount of security of tenure, no officer being now dismissed without the consent of the Board of Supervision.

Dr. MAJOR GREENWOOD remarked that, in his opinion, the position of medical officers of health would be much improved if more members of the profession took an interest in local matters or deigned to come forward as candidates for places on the sanitary boards of their districts. In his own district, an important metropolitan one with a population of 150,000, on a board of 120 members he was the only medical representative, and, so far from getting any encouragement from neighbouring practitioners, he was rather rebuked for having anything to do with local matters. When endeavouring to promote sanitary reform in his district he sadly missed the presence of other medical men on his board, and he felt sure that a greater leaven of members of the profession in the various sanitary authorities throughout the country would make a world of difference in the position of medical officers of health, both as regards their influence for the public good and their own proper remuneration.

The PRESIDENT of the Section read a letter from Dr. Grimshaw of Dublin, calling attention to the great advances in the public medical service of Ireland, and advocating a

Digitized by Google

further improvement in the system by the appointment of medical superintendents who possess a high sanitary qualification, and that the tenure of office should be made more secure.

Dr. ALLFREY, as the result of considerable experience, approved of Dr. Grimshaw's suggestion. He thought that the offices of medical officer of health and of vaccination might be usefully combined, and was strongly of opinion that medical officers of health should not engage in private practice.

The PRESIDENT having replied, the discussion terminated.

SURGERY.

The proceedings of this Section were opened by the President, Mr. JESSOP, who introduced a discussion upon the Treatment of Cancer of the Rectum. As regards the treatment of cancer by drugs, his attitude was one of hope and even faith in the future, but absolute distrust in the past. Some Pasteur of the future might yet discover a cure for cancer, but the claims put forward for Chian turpentine or any other drug rested upon the slenderest of foundations. Cancer never yet was cured, although medicines might give great relief. He passed on to operative treatment of cancer of the rectum. Partial removal was rarely advisable and barely scientific. He would deal only with proctectomy, which of late had been forced into prominence by the success of German operators. His own experience was limited to seven cases. One died in a few days; the remaining six obtained a varying amount of relief. All were still alive, one apparently well at the end of twenty-one months; a second equally well at the end of seventeen months; a third had had a speedy return of the disease, which now threatened to end fatally; two others were still well at the end of five months and twenty-six weeks respectively. In four of the cases the results had been almost all that could be desired, and incomparably better than those of the most exceptional colotomy. He had not yet attempted the removal of cancer when beyond the reach of the examining finger, nor had he advised the operation in any male in whom the disease was seated in the anterior wall of the rectum. In thin wasted patients access might be got to the disease by expanding the sphincter by a modified Weiss's dilator, but in stout persons it was necessary to cut from the rectum deeply down to the coccyx. Much of the success of the operation depended on the thorough cleansing of the wound, not only at the time of the operation, but during many subsequent days. In cases in which the disease had originated beyond the reach of the finger, or had crept up to a higher level, he thought the operation unsuitable. He spoke next of colotomy. His opinion was that in cancer of the rectum obstruction was not much to be feared if the disease were in the lower half, but was almost certain where the upper portions of the rectum are involved. Of fifty-four cases of colotomy taken from his note-book, performed for the relief of distress, and not for obstruction, three only died in the first month. Given the diagnosis of cancer high up in the rectum, the duty of the surgeon is to recommend without delay the formation of an artificial anus. As regards cases of disease affecting the middle and lower portions of the rectum, he found that the average duration of life in those who were not operated on was a little over seventeen months, whilst that of those who underwent colotomy was twenty-two months and a half. His experience had gradually raised his estimate of colotomy as a means of prolonging life. As regards relief of suffering, his conclusions were that operation lessened pain, diminished the desire to evacuate, prevented incontinence of fæces, and reduced the number of motions. He had hitherto only performed the lumbar operation, but he was favourably impressed by the evidence in favour of inguinal colotomy.

A discussion followed.

DISEASES OF CHILDREN.

Mr. THOMAS SCATTERGOOD, President of the Section, opened the proceedings by welcoming the members present. He regretted that, owing to various reasons, many of those who had been expected to take part in the discussions had been prevented from being present.

Dr. ASHBY (Manchester) introduced the subject which had been arranged for discussion—viz., "Paralysis of the first Two Years of Life." He referred to this under the following heads: (1) Intra-uterine meningo-encephalitis; (2) meningeal hæmorrhage and consequent brain injury; (3) syphilitic arteritis and softening; (4) acute cerebral paralysis, mostly hemiplegic; (5) anterior polio-myelitis; (6) peripheral paralysis. He pointed out the differences between the brain of the infant and that of the adult, especially emphasising the exceeding delicacy of the vessels of the pia mater and the soft condition of the brain. He illustrated the mechanism of meningeal hæmorrhage by reference to many cases of post-mortems made on newly-born children. He referred to the rarity of paralysis due to syphilitic arteritis during early life, and gave the details of a case of syphilitic arteritis and softening giving rise to spastic paralysis, both arms and legs being affected. In reference to acute cerebral paralysis, he especially called attention to the high temperature usually present and to convulsions as being important factors in producing the hemiplegia. He doubted if embolism would account for all the cases.

Dr. MANSEL SYMPSON read notes of two cases of Cerebral Palsy. In one there had been right hemiplegia since birth, which was curiously associated with migraine. It was due to cortical atrophy, caused by meningeal hæmorrhage. The second was a case of right hemiplegia with aphasia, the attack having followed measles at the age of three years and a half.

Dr. MANTLE read a paper on the Causes of Laryngismus in Young Children, with special reference to its production by Elongation of the Uvula. He mentioned an extreme case, lasting four months, in which convulsions took place, the patient being eventually cured by the removal of the uvula. Dr. Ringer was the only author he could find who had remarked upon the causation of laryngismus by a morbid condition of the soft palate. He advised cold sponging and fresh air as very important aids to cure.

THERAPEUTICS.

The proceedings of the Section were opened by the President, Sir WILLIAM ROBERTS, who gave an address upon some Practical Points in the Use of Antacid Remedies in Dyspepsia and Gravel. He remarked upon the great change which had taken place in the minds of medical men regarding the action of remedies. Forty years ago the leading minds of the profession seemed to have regarded with a sort of despair any hope of seriously influencing the issues of disease by the use of drugs. Some of them even gloried in a course of *laisser aller*, *laisser faire*, and turned their attention entirely to a study of the natural history of disease and the minutiæ of morbid anatomy. Now all this was changed. A more exact investigation of the fundamental action of drugs on the tissues and organs, and the discovery of the remarkable correspondence which has been found to exist between the chemical composition of substances and their physiological effects, have given a new and extraordinary impetus to therapeutical studies. Sir William Roberts went on to say that there were few simpler problems than those relating to the palliative treatment of acid dyspepsia and the chemical prophylaxis of uric acid gravel, but there were some practical points in carrying out the treatment which were neither simple nor well known. Antacid agents might be classified into those which were designed to take effect in the stomach, or gastric antacids; and those which were designed to take effect in the kidneys, or renal antacids. The gastric antacids in common use consisted of the alkaline and earthy carbonates and lime-water. Renal antacids combined, in addition to these, the acetates and citrates of potash and soda, which were changed in the *primæ viæ* into carbonates of these bases. Gastric antacids were employed in two distinct classes of cases—namely, in acid dyspepsia, and in a variety of conditions characterised by great irritation of the stomach, often with vomiting, which we sought to allay by the administration of milk mixed with lime-water. For acid dyspepsia the lozenge was the best mode of administration of an antacid. The Pharmacopœia had two lozenges of this kind, the troch. sod. bicarb. and the troch. bismuthi. The latter was to be preferred. It owed its antacid properties to the chalk and magnesia which it contained, the bismuth being probably inert. Many lozenges sold in the shops contained pungent spices which were injurious. The Vichy lozenges were valuable, but rather costly. It was well to vary the antacid from time to time. The question might now be put, Is there any harm in the practice of habitually using antacids for the relief of acid dyspepsia? He had naturally at one time

Digitized by Google

regarded the practice with misgivings, but a more extended experience had led him to believe that it was harmless. He used the bismuth lozenge largely, but with the following precautions. They were not to be used at or near meal-times; they were not to be used regularly or systematically, but only when gastric pain was present and produced real discomfort; lastly, the use of the lozenge was to be discontinued if it failed to cut short the pain. Lime-water and milk was a favourite remedy, and often very successful. It sometimes failed, owing to the very low saturating power of lime-water. It was often desirable to substitute a solution of from five to ten grains of bicarbonate of soda per ounce for the lime-water. The use of renal antacids rested on an equally rational basis. To prevent uric acid gravel forming we had only to keep the urine alkaline; but, simple as this was, there were some practical difficulties in the way, owing to the persistence of the tendency to the uric acid formation. It was very important to remember that this tendency did not last throughout the entire twenty-four hours, the necessary conditions being only present during the hours of sleep. It followed that if we safeguard the night, the day might generally be left to take care of itself. In the milder cases a full dose of the alkalising agent at bedtime was sufficient. The citrate of potash was the best preparation. The dose for an adult should not be less than from 40 to 60 grains, dissolved in three or four ounces of water. In severer cases a second dose should be taken about the middle period of the hours of sleep. In still more severe cases additional doses might be required, but usually only temporarily. The essential point in the prophylactic treatment of uric acid was to guard the urine from precipitating within the precincts of the kidney. An antacid which was too feeble to render the urine actually alkaline might postpone the time of precipitation.

OBSTETRIC MEDICINE.

On Wednesday, the President, Dr. CULLINGWORTH, opened this Section with some suggestions towards the further application of antiseptic principles to midwifery practice. He pointed out that the very fact of the use of chemical disinfectants being an essential part of the antiseptic method carried with it the danger of regarding the part they play in the treatment too exclusively, and of neglecting other means of ensuring antiseptic cleanliness, which, though perhaps subsidiary, are nevertheless of the greatest importance. Amongst these means he particularly mentioned the avoidance of frequent vaginal examinations, especially during the first stage of labour; the immediate removal from the uterus of matters retained either after labour or after an incomplete abortion; the desirability of allowing patients after a normal labour to sit up in bed occasionally on the second or third day, so as to carry out the great antiseptic principle of drainage; the immediate suture of the perineum wherever the tear is at all considerable; and the more general substitution of absorbent pads for the old-fashioned linen diaper. Our zeal for the safety and well-being of the recently-delivered mother ought not to make us wholly unmindful of the newly-born child. Could we usefully apply antiseptic principles to the management of the infant? The answer was, that we could in at least two ways—viz., in the adoption of means to prevent ophthalmia, and in the mode of dressing the remains of the umbilical cord. In regard to the former, Dr. Cullingworth recommended, in addition to the wiping of the child's eyes with a clean, soft, dry cloth as soon as the head was born, and if possible before the eyes were opened, the application of a solution of corrosive sublimate (1 in 3000) by squeezing over each eye a saturated pledget of cotton wool immediately after the first washing. Credé's method of dropping in a 2 per cent. solution of silver nitrate need only be adopted in cases where the mother was known to have suffered from a purulent vaginal discharge. The report of a committee of the Ophthalmological Society showed that from 30 to 40 per cent. of the inmates of blind institutions in Great Britain and Ireland owed their blindness to purulent ophthalmia in their infancy; hence it was not unreasonable to infer that, by the adoption of the means of prevention here suggested, the amount of blindness at present existing in this country might be diminished by one-third. With regard to the dressing of the umbilical cord, it was pointed out that the normal course of events was for the remains of the funis, after division and ligature, to dry and shrivel up, and for separation of the desiccated and dead tissue to take place within a few days, leaving a raw surface analogous to the placental site on the inner aspect of the mother's uterus, and liable, like it, to be a channel for septic absorption. The objects to be aimed at, therefore, were to secure (1) the normal desiccation of the cord before its separation, and (2) an aseptic condition of the wound left when separation has taken place. The method recommended was, after drying the surface of the cord, to powder it plentifully with powdered starch and wrap it in a square of antiseptic gauze. The umbilical wound should be dusted freely with finely powdered boric acid, and covered with a pad of dry absorbent wool. Allusion was then made to the sectional arrangements, and especially to the considerations which had led to the selection of subjects for discussion. The address concluded with some remarks on the combativeness of the present race of gynæcologists, which was to be explained by the science of gynæcology, being in its youthful stage. When our knowledge had a firmer basis, we should differ less.

On the termination of the President's address, Dr. BRAXTON HICKS opened a discussion on the treatment of Placenta Prævia, and recommended the following method. 1. After the diagnosis of placenta prævia is made, proceed as early as possible to terminate pregnancy. 2. When once we have commenced to act, we are to remain by our patient. 3. If the os is freely expanded and the placenta marginal, rupture the membranes, and wait to see if the head is soon pushed by the pains into the os. 4. If there be any slowness or hesitation in this respect, employ forceps or version. 5. If the os is small and the placenta more or less over it, carefully detach the placenta from round the os, and if no further bleeding occurs we may wait an hour or two; but should the os not expand, and if dilating bags are at hand, the os may be dilated. If it appears that the forceps can be admitted easily, they may be used; but if not, version by the combined internal and external method should be employed, and the os plugged by the leg or breech of the fœtus; after this is done, the case may be left to nature, with gentle assistance, as in footling and breech cases. 6. If the os is small, and if we have neither forceps nor dilating bags, then combined version should beresorted to, leaving the rest to nature, gently assisted. 7. If during any of the above manœuvres sharp bleeding should come on, it is best to turn by the combined method in order to plug by breech. 8. When the fœtus is dead, or labour occurs before the end of the seventh month, version by the combined method, no force following, is the best plan. To these Dr. Braxton Hicks added, if we employ a routine method in most cases, it will be found that version by the combined method, no force following, gives a result as good as, if not better than, any. As to after-treatment, act on modern principles. Should oozing occur after expulsion of the placenta, swab the lower uterus by styptics, and irrigate tho uterus daily with some antiseptic solution, and particularly, if irrigation cannot be done, insert iodoform pessaries in the vagina. This is especially useful if the outlet of the uterus is blocked by adherent clots.

Dr. MURPHY (Sunderland) strongly urged the necessity of realising the extreme danger of leaving cases of placenta prævia to go on after they were once diagnosed, and wished to establish a rule that premature labour should be induced as soon as it is ascertained that the placenta presents, after the seventh month of pregnancy, and even before this should bleeding be serious or frequently recurring. He advised that the obstetrician should remain in constant attendance during the whole period of labour, which could be best induced by Barnes's bags, and then the question must be decided how further to conduct it. Generally separation of the placenta, full dilatation of the os, and bipolar version would give the best results. He submitted a table of thirty-eight cases, with two deaths; there had been a series of thirty-two consecutive recoveries included in this list.

The PRESIDENT read a letter from Dr. Lomer, in which he gave the greatest credit to Dr. Braxton Hicks for his method of treatment. He had treated twenty-eight cases by the combined method of turning, with one death of the mother and with thirteen living children. Putting together all the German statistics, there were 190 treated by Dr. Hicks's method, with only nine deaths. Dr. Lomer's rule was as follows. Turn, and then wait; consider the case as being simply one of foot presentation, in which there is no other reasonable necessity to extract the child than the impatience of the operator. Should hæmorrhage occur in the

Digitized by Google

meantime, then naturally it is right to perform slight tractions on the foot in order to make the breech of the child tampon the bleeding parts; this traction ought, however, not to be a "hastened extraction."

Dr. ROBERT BARNES said, if he had been a German probably what was now called Bandl's ring would have been styled Barnes's boundary line, as he had long ago described it as the boundary line of dangerous hæmorrhage, which must be dilated to allow the child's head to pass. He recommended (1) puncture of the membranes, (2) separation of the placenta, (3) dilatation of the os by his rubber bags, and (4) forceps or turning according to the circumstances present. He said the prophylaxis of placenta prævia was of importance, as this complication was liable to recur. Attention should be given to the endometrium so as to get it into a healthy state.

Professor HARVEY (Calcutta) said treatment must vary according to the nature of the case.

Dr. WALTER (Manchester) gave details of twenty-three cases seen by him. The mode of delivery was in one case by forceps, in three by natural labour, and in nineteen by version. In hospital practice his mortality to the mother was 10 per cent.; in private practice he had no maternal deaths. He spoke highly of Dr. Hicks's method.

Dr. BERRY HART (Edinburgh) showed specimens (frozen sections) of placenta prævia, and spoke on the definition of the terms used in relation to the hæmorrhages at the end of pregnancy.

Dr. MORE MADDEN and Dr. MURDOCH CAMERON also spoke.

The following papers were then read: "The Mechanics of Puberty," by Dr. Johnstone (Danville, U.S.A.); "Some Points in the Treatment of Uterine Cancer," by Dr. More Madden; "Some Practical Points in the Surgical Treatment of Cancer of the Uterus," by Mr. Stuart Nairne; "Vaginal Hysterectomy for Cancer, with Notes of Ten Cases," by Professor Japp Sinclair. Dr. Walter (Manchester) gave details of a case of Total Extirpation of the Uterus for Cancer.

In the discussion which followed on the "Cancer" paper, the PRESIDENT gave the following statistics of the results of total extirpation at Dresden. From 1883 until 1889 there had been 160 cases of total extirpation of the uterus, with a mortality of 5·4 per cent. Leopold had reported 48 of these cases; of the remaining, 80 were cases of carcinoma, and of these 62 are living; in 3 there were signs of recurrency, 4 died at once; 14 died later (10 owing to recurrence); 59 were cured—some certainly, others possibly; and 52 cases occurred in succession without a death.

Dr. BRAITHWAITE (Leeds) gave details of seven cases of total extirpation of the uterus done by him with one death.

Dr. Campbell, Dr. Cameron, Dr. Bell, and Dr. Barnes also spoke in the discussion.

THE MAYBRICK CASE.

THE trial of Florence Elizabeth Maybrick for the wilful murder of her husband, James Maybrick, by poisoning him with arsenic last May, commenced on Wednesday, the 31st ult., and ended on Wednesday, the 7th inst., in a verdict of guilty and sentence of death. It was tried at the Crown Court, Liverpool, before Mr. Justice Stephen. Mr. Addison, Q.C., M.P., Recorder of Preston, led for the prosecution, with Mr. W. R. M'Connell and Mr. Swift; Sir Charles Russell, Q.C., M.P., with Mr. Pickford, appearing for the defence. The greatest interest was taken in the proceedings, the court being crowded each day. The case for the prosecution occupied three days and a half; that for the defence nearly a day and a half. The learned judge's summing up took up the whole of Tuesday, the 6th, and more than one half of the next day, and a more exhaustive recapitulation of the whole case could not have been made. The following is a condensed history of the more important medical features of the case as given in evidence.

The deceased was a Liverpool cotton-merchant, having an office in the city, and a residence at Aigburth, a suburb situated a few miles south of Liverpool. His age at the time of his death was fifty; he had been married eight years, the issue of the marriage being a boy aged seven and a girl aged three. The deceased and his wife lived apparently on happy terms until the day of the last Grand National Steeplechase, when they had a very serious quarrel, which was, however, on the intervention of Mr. Hopper, the family medical attendant, apparently made up. The deceased's health was described by Mr. Hopper and his relatives as being fairly good. His brother denied positively that he was in the habit of taking arsenic, and it appeared that the deceased had indignantly denied it. The deceased's family history was good, and his life was insured. On Sunday, April 14th, Mr. Fuller, of Albany-street, London, saw the deceased at the residence of his brother, Mr. Michael Maybrick, Wellington Mansions, Regent's Park. He complained of a little pain in his head and numbness in his legs; he was apprehensive of paralysis. Mr. Fuller spent an hour with him, examined him fully, and expressed his opinion that there was nothing the matter with him beyond indigestion, for which he prescribed acid. nit. mur. dil. with nux vomica and syrup. He also ordered a compound camomile pill, and in a second prescription extract of cascara, some glycerine, and cream of tartar. The deceased called at Mr. Fuller's residence the following Saturday, April 20th, and expressed himself as much better; the prescriptions were varied a little. Mr. Fuller never prescribed arsenic, and nothing was said to him about it. On Sunday, April 28th, Dr. Humphreys, who resides not far from the deceased's residence, was sent for, and found him in bed. Except for a trifling injury, he had not previously attended him. He complained of some peculiar condition of his chest and heart, was afraid he would be paralysed, and referred his symptoms to a strong cup of tea, adding that upon several previous occasions tea had produced similar inconveniences. He complained of the dirty state of his tongue, which he said had been furred and dirty for a long time, and that he could not get it clean. He had been at the Wirral races the day before, had dined with a friend, and while at dinner his hands were so very unsteady and twitching that he spilt some wine, which distressed him very much, as he feared his friends might think him drunk. Dr. Humphreys prescribed dilute prussic acid, and advised him to have nothing that day except milk and soda. He was called again to him that evening, and found him suffering from stiffness of the legs, for which he prescribed bromide of potassium and tincture of henbane. He called the next day; the deceased was better, but remained in bed, and, concluding that it was a case of chronic dyspepsia, Dr. Humphreys ordered him a dietary in writing and Seymour's preparation of papain and iridin, one teaspoonful a day. On May 1st the deceased was much better, his tongue was clean, and the headache had disappeared. On Friday he complained of being worse, and that the medicine did not agree with him. Dr. Humphreys assured him he was better, and at the deceased's request allowed him to go to town and to have a Turkish bath. He met him in town that afternoon, but had no conversation. At midnight Dr. Humphreys was again sent for; the patient was in bed in great pain, which he referred to his thighs, hips, and knees. He had been sick, which he attributed to inferior sherry put into his Revalenta Arabica food. The sickness continued, and on the following Sunday, May 5th, Dr. Humphreys proposed a consultation, to which Mrs. Maybrick objected on the ground that he had had so many doctors and that they had done him little good. But Dr. Humphreys being puzzled with the case, and the deceased's brother insisting upon a second opinion, Dr. Carter was called in and saw him on Tuesday, the 7th. He examined him thoroughly, and found nothing wrong with the heart, lungs, liver, or brain; diarrhœa was just commencing; the throat was much inflamed, red, dry, and glazed. The deceased complained of a sensation as of a hair in his throat, and some vomited matters and fæces were shown. Drs. Carter and Humphreys agreed that it was a case of acute dyspepsia resulting from improper food or drink, or both. On the 9th tenesmus was present, and there was looseness of the bowels, examination of the rectum causing such pain that it had to be abandoned. The symptoms strongly suggested some irritant, and about this time, circumstances exciting strong suspicions against Mrs. Maybrick having arisen, nurses were in attendance, with strict orders that the deceased was to have no food except what they themselves prepared in the rooms. Dr. Humphreys tested some urine and fæces, with a negative result; Dr.

Digitized by Google

Carter tested some Neave's food, with the same result; but in a bottle of Valentine's meat juice he got distinct evidence of arsenic, both by Reinsch's and Marsh's tests. It was too late, however, to save the life of the unfortunate man, who sank and died on Saturday afternoon. On Monday a post-mortem examination was made, Dr. BARRON, pathologist of the Royal Infirmary, representing Mrs. Maybrick. There were no indications of any natural cause of death, and the appearances of the stomach, intestines, and rectum were those which would be produced by an irritant poison, such as arsenic. That the cause of death was an irritant poison was the opinion of all the three gentlemen who made the post-mortem examination; but Drs. Carter and Humphreys also expressed a decided opinion that it was a case of death from arsenical poisoning after hearing the result of the chemical examination by Mr. Edward Davies, analyst. That gentleman found arsenic in the liver, in the intestines, and in the kidneys, the total quantity in the abdominal viscera being estimated at one-eighth of a grain. Mr. Davies also found arsenic in the bottle of meat juice handed to him by Dr. Carter, the quantity being about half a grain. He found arsenic in many other articles sent him from the house, including a bottle of mixture made up from Mr. Fuller's prescription by Messrs. Clay and Abraham, a firm of Liverpool chemists, and proved the absence of any arsenic in another bottle of the same mixture found at the deceased's office, as also in all the bottles of ingredients from which the prescription had been made up. In the jug, basin, and pan from which the deceased warmed and took his lunch at the office, Mr. Davies found distinct evidence of arsenic, from which he inferred that there must have been a very decided quantity of arsenic in the whole of the food, as he had obtained crystals of arsenic from the small fragment which remained adhering to the jug even after it had been washed. On comparing the specific gravity of the fluid in the Valentine's meat juice bottle with that of a fresh sample, Mr. Davies concluded that the arsenic had been introduced in a fluid form. A basin containing fly-papers soaking in water was found by the housemaid in Mr. and Mrs. Maybrick's bedroom covered over with a towel. It was shown that Mrs. Maybrick had purchased fly-papers from several chemists, alleging that the flies were beginning to be troublesome, which was not correct. Arsenic was also detected on the front and in the pocket of a dressing-gown, on a handkerchief, and a bottle contained liquid with from twelve to fifteen grains of solid arsenic, also water and powdered charcoal. It was identical with some powder found in a packet and labelled "Poison for cats." A tumbler containing milk and a handkerchief was found to have between twenty and thirty grains of arsenic in it. A bottle of Price's glycerine also contained arsenic. Mrs. Maybrick was seen by one of the nurses to remove the bottle of Valentine's meat juice into another room—afterwards found to contain arsenic,—to return with it in a very suspicious manner half hidden in her hand, and to replace it on the table. The nurse gave it to Mr. Michael Maybrick, who delivered it to Dr. Carter. The lunch taken on May 1st was wrapped up in brown paper and given by the prisoner to Mr. Edwin Maybrick, who gave it to his brother. The latter ate it in his presence, and complained of it as having made him ill. It was in the remains of this that Mr. Davies found the arsenic.

Dr. Stevenson, Professor of Forensic Medicine in Guy's Hospital Medical College, and Analyst to the Home Office, received some of the viscera to examine, and was the last witness called for the prosecution. His analysis confirmed that of Mr. Davies, with the exception that he estimated the proportion found in the liver as larger. He expressed his opinion that death resulted from poisoning by arsenic.

For the defence, Dr. Tidy, the Lecturer on Medical Jurisprudence at the London Hospital Medical College, who was called on the same day as Dr. Stevenson, contended that it was not a case of arsenical poisoning. He argued that the four symptoms—vomiting, purging, pain in the stomach, and soreness of the eyes—were absent, and that the small quantity of arsenic found in the body of the deceased was accountable for by the alleged habits of the deceased. Evidence from America was brought by two witnesses, who testified to the deceased having taken arsenic some years ago, and by a retired Liverpool chemist, who identified the deceased by means of a photograph, who deposed to the fact of the deceased having gone to his shop to have "pick-me-up's" containing doses of Fowler's solution. Dr. Rawdon Macnamara, of Dublin, also gave evidence for the defence, contending that the deceased's symptoms did not correspond with those of patients suffering from poisoning by arsenic. Mr. Paul's evidence went to show that there was arsenic in the glazing of the pan in which the lunch was warmed, which might be set free by muriatic acid. He also contended that if arsenic had been present in the urine it must have shown itself by Reinsch's test which Dr. Humphreys employed.

Mr. Justice Stephen, in summing up, alluded to the partisan character of expert evidence, quoting also the old saying that "a physician was a man who put medicine, of which he knew little, into a body of which he knew less." He deprived the sarcasm of its sting, however, by the compliments which he paid to the various medical witnesses, the whole of whose evidence, as well as that of others, he went carefully through. At her own request the prisoner was allowed to make a statement. She stated that the solution of fly-papers was for a cosmetic, as her mother and some friends in Germany could have testified. She added that she put some white powder in the meat juice at her husband's request, and, as some of it was spilt, filled it up with water.

The jury were only absent from court about forty minutes, and returned with a verdict of "Guilty." Sentence of death was pronounced upon the unhappy woman, who throughout the whole of the long trial, and in a close court, in sultry weather, bore herself with most remarkable firmness.

The case resembles in some points that of Wooler, in others that of Madeline Smith; but it has its own peculiar features. As in Wooler's case, the poison was arsenic, and it was suspected during the deceased's lifetime. But there was not the same delay in coming to a conclusion as to the real nature of the case, or the same performance of Reinsch's test with acid contaminated with arsenic. The cosmetic theory set up in Madeline Smith's case was again set up here.

Pharmacology and Therapeutics.

SOMMERBRODT ON CREASOTE IN TUBERCULOSIS.

PROFESSOR SOMMERBRODT of Breslau, in two communications to the *Therapeutische Monatshefte*, declares that an experience of over 5000 cases has proved to his own satisfaction that creasote is not merely a useful drug for the symptomatic treatment of tuberculosis as has been conceded by others, but that it exerts a specific influence on the disease by the resistance it offers to the cultivation of tubercle bacilli. Dr. P. Guttmann had by his experiments shown that tubercle bacilli could scarcely be cultivated in sterilised serum containing 1-4000th of its volume of creasote, and the culture entirely failed when the solution was a little more concentrated. He concludes that if it were only possible to administer sufficient creasote for the blood to contain that drug for some time in the proportion of 1-4000th of its own quantity, tubercle bacilli would probably cease to develop. This, he contends, is impossible, not only because the required quantity of creasote in the blood would be more than twenty grains, but because it would be impossible to determine what quantity of creasote would have to be administered to make twenty grains of it circulate in the blood. Sommerbrodt believes that it is possible to give the necessary quantity of creasote. He has been prescribing for some time to many hundreds of tuberculous patients capsules of creasote, each containing one grain of the drug. These capsules were taken, three the first day, and every succeeding day one more until the eighteenth day, after which the same quantity—from twenty to twenty-five grains per day—was continued for many months. The author says that it is impossible to presume that the twenty grains of creasote have already entirely passed out of the blood by the time the second or third dose of the drug is given, so that probably such an accumulation of creasote takes place in the tissues as to fulfil Dr. Guttmann's postulate. He has at any rate had the most gratifying success with this medication, and his experience was that the more creasote a patient could bear in a day the greater was this success. The *modus operandi* of the creasote, Dr. Sommerbrodt says, has not yet been sufficiently cleared up. The drug is certainly a stomachic tonic and diminishes the secretions, but these can hardly be its chief effects. He rather believes, although

Digitized by Google

the experiments on animals have so far led to negative results only, that a sufficient quantity of creasote must make the soil unsuitable for the cultivation of tubercle bacilli. He suggests therefore that serum from a man who has for some time taken more than twenty grains of creasote be used to cultivate tubercle bacilli, so as to find out if this acts differently from the serum of another person used for the same purpose.

SULPHUROUS ACID GAS IN FAVUS.

Dr. Schuster of Aix-la-Chapelle, in a paper on the treatment of favus, published in the *Monatsschrift für praktische Dermatologie*, describes the treatment he has adopted in place of the old one, which, after months of application, is so often unsuccessful. He applies sulphurous acid gas to the affected head in the following ingenious way: a net of strings is made across the lower third of an open cardbox cylinder, which is fitted to the head like a hat, and which can be closed by a cover of the same material. A saucer containing burning sulphur is passed through the open top and laid on the net of strings, and the whole covered up and hermetically sealed. The patient must sit still for half an hour. The whole cylindrical space is filled with sulphurous acid gas, which does not pass off even in that space of time, though the sulphur itself is of course extinguished after all the oxygen has been used up. The treatment is repeated daily, and a favourable effect is always observed after a few sittings, while in from six to eight weeks the head is free from favus, presenting in its place smooth white bald patches. The hair must of course be cut short, and the scabs softened with oil and removed, and the whole head washed with soap. Dr. Schuster believes the same treatment would be found suitable for ringworm.

THE TREATMENT OF FURUNCLES.

Staff-Surgeon Leu of the German army sums up a long communication to the *Deutsche Militärärztliche Zeitschrift* on the treatment of furuncles with the following conclusions. Subcutaneous injection of carbolic acid is a simple and effectual abortive treatment of furuncles. Incipient furuncles which have not yet suppurated are especially adapted for this treatment. A cure results in these cases without necrosis of connective-tissue; in the more advanced furuncles which have formed pus or are even discharging it, no deforming cicatrisation follows. The proper strength of the carbolic acid is 3 per cent. This mode of treatment is particularly valuable in the army, because it shortens the time on the sick list (when it is necessary to put the man on at all), and he returns to duty with a better cicatrix, while many may be treated without going to hospital. The simplicity of the apparatus required, consisting only of a Pravaz syringe and a small bottle of carbolic solution, makes it possible to apply the same anywhere and at all times—for instance, during manœuvres and on the march.

TORTURING AND STARVING FISH.

By J. LAWRENCE-HAMILTON, M.R.C.S.

IT is sad to relate that in the fish trades of the United Kingdom those professionally and pecuniarily interested and engaged in fish torturing and in fish starving have, in the ignorant thoughtlessness of chronic custom, been alike blinded to the sacred civilising duties of humanity and Christianity, and at the same time have overlooked and omitted their own material profits and advantages. I shall show that fish starving is a domestic sport which simultaneously diminishes the commercial value of the fish; it ruins the flesh, flavour, and firmness of the fish; it tends to induce parasitic, bacterial, and other diseases in the fish; it diminishes the weight of the fish, and increases its cost both to the professional fish starver and to the consumer—the general public. Fish so starved are more liable to rapid decomposition soon after death, and in codfish such starved fish are more difficult to crimp, which are additional causes and circumstances tending to enhance the avoidable risks of the present fish trade, and therefore an unfair tax on the consumer. The average absolute loss in weight of codfish by starvation and imprisonment appears to represent 10 per cent. of the entire weight of the natural normal healthy fish, a heavy avoidable commercial loss. The close confinement of codfish in their fish chests sunk in the fish docks causes a rapid increase in the relative number of bacteria always present in the blood of living fish, and when the proportion of bacteria exceeds that which the blood of living fish can tolerate, then the fish commences to sicken and will often die, even if well and regularly fed in a fair amount of space, as in the well-cared-for fish kept in aquaria but too often illustrate. Hence it is that these sunk fish trunks become the rapid carriers of contagious disease to any healthy fish which may chance to be in or near the fish chest.

It is known that fish, in addition to tolerating in health a certain proportion of bacteria, are also, up to a certain point, equally tolerant of various external and internal parasites, and generally every fish dissected shows either some parasites—as tapeworms—in its intestines, or other parasites about its gills, eyes, skin, or elsewhere, and even sometimes as many as fifteen different species of parasites have been discovered in one individual fish. Often these parasites, along with the bacteria, increase so as to gain the battle over the fish, especially when the latter becomes weakened by starvation, confinement, injury, or other causes tending to diminish its vitality. Parasites also promote decomposition the moment the fish dies. These sunk fish chests never err on the side of cleanliness, and are hence favoured localities for hatching and breeding bacteria and parasites specially destructive to fish health and fish life. Later I hope to be able to publish a detailed illustrated pamphlet on this subject. The loss of life in codfish caught in the nets will not average upwards of 5 per cent. Hooked fish on being drawn up are liable to disgorge or vomit not alone the contents of their stomachs, but also, especially in the case of deep-sea and abyssal fishes, to have their stomach and part of their intestines protruded through their mouths. Deep-sea and abyssal fishes, fish having air-bladders, by the rapid altered pressure, together with the influence of shock, get their air-bladders so dilated with evolved gases that they are unable to sink from the surface of the water in welled smacks till the fisherman, passing a long needle through the walls of the fish's abdomen, or the pit of the left pectoral fin, by letting the gases escape, allows the fish to resume its natural habits. Hooked salmon vomit through fright alone. Fish may be sometimes seen with a prolapsed and protruded rectum and lower intestine, which appears to be due to relaxed flabby muscles, and is a sign which, very shortly precedes the commencement of decomposition. As a rule, hooked fish keep longer fresh than netted fish. Netted fish, owing to being long injured by having been trawled over rough grounds, together with the sharp prolonged squeezing and banging about which they get in the nets, are, like over-driven cattle, specially liable to early decomposition.

Much of the so-called best prime "live" codfish at Billingsgate has after capture been transferred into welled smacks which accommodate from about 600 to 1000 codfish, each weighing from 16 lb. to 20 lb. avoirdupois, where, especially in rough weather, after having been subjected for a few days to injury, confinement, and starvation in the welled boats, to prevent these fish from eating one another they are sometimes specially secured by their tails. On arriving in port some forty of these codfish are tightly crammed into a fish chest, which is sunk in the fish dock (which in England answers only during the cold weather, from about November till April), where the codfish, after further confinement and starvation, all die within a few weeks. If the fish be kept for a shorter interval—say, a fortnight—then on an average only about 10 per cent. of such codfish are found dead upon opening the raised chest. All such starved, closely-confined codfish lose much of their natural healthy flavour, firmness, weight, and plumpness. The fish having to support life, consume much of the substance of their own livers, which appear small and shrunk when compared with the normal liver of a freshly killed healthy fish. Consideration of the chemical and microscopic changes thus artificially induced I propose to postpone for a subsequent occasion. This codfish, if not previously dead, is then stunned with a blow from a big mallet, and thus, whilst insensible, crimping is alleged to be carried on. As the sensibility never returns there is practically no cruelty. Skate are said sometimes whilst still alive to be crimped by fishmongers. So long as cod will "crimp," or show muscular contraction it is called in the fish trade "live cod," an intentional misrepresentation.

Digitized by Google

Out of its healthy season, a woolly, watery codfish is often appropriately termed by the fishermen "churchyard" cod. Recollecting these facts, the familiar dry, flabby, cotton wool-like taste of the vaunted best prime "live" codfish so often sold at Billingsgate and elsewhere is easily explained. Skinning live eels and gutting live fish, causing avoidable, useless torture, are occasionally practised.

Lobsters and crabs are often kept alive on wet seaweed or ferns, and live on an average in hampers for a couple of days, starving before they reach the fishmonger, who frequently keeps them, if not sold, till they die of starvation. Lobsters and crabs thus starved to death lose weight, firmness, taste, and flavour, and immediately on death tend to decompose rapidly, which in such conditions is but slightly diminished by boiling in salted water. Instead of puncturing their brains with a stilleto, wriggled about so as to break up the animal's brain material, and then plunging the crabs and lobsters into boiling water, out of sheer thoughtlessness and careless custom, living lobsters have been placed in cold water which, whilst it is being heated up to the boiling point, causes the animal unnecessary and easily avoidable torture, for if plunged into boiling water it quickly dies. However, previously to boiling crabs and lobsters, to rid them of sand and dirt they should be well washed in fresh flowing water. Although no fish or shell-fish is legally protected against cruelty in this country, and although it is not punishable to boil fish alive, to roast fish alive, to slice fish alive (as turtle used to be in Ceylon, and as some air-breathing fish carried about in earthen pots in China are still), yet it is to be expected that these cruelties will rapidly disappear as soon as fish traders find that humanity to animals will benefit their own pockets. Codfish would keep in excellent health and condition if kept free in artificial ponds or docks fed with sea water, as was the custom among the ancient Romans and ancient Egyptians. The present St. Petersburg fish farms or ponds, fed by the river Neva, and where each species of fish has a separate compartment, yield profitable rentals. Lobsters and crabs can be fed on almost any fish refuse. The English law is curious as regards cruelty to animals. Scratching a tame rabbit so as to draw its blood is punishable with three months' imprisonment with hard labour, whilst the law permits anyone to roast a *wild* rabbit alive without any interference. Possibly the Legislature considers fish as wild animals, and therefore beyond and outside the jurisdiction of the law courts.

ALKALI MANUFACTURE.

THE twenty-fifth annual report of the chief inspector of alkali works presents upon the whole a favourable view of the work of his department during the past year. The best results of supervision are to be found in the improvement of the processes under inspection which tends to render supervision less necessary, and such an improvement appears to be slowly taking place in connexion with the industries under his care. Thus, a summary table given in the report shows that the average amount of acid gas discharged into the atmosphere from works of this description during three years past has very considerably diminished. The comparison of 1887 with 1886 does not indeed show uninterrupted improvement, since in the item of sulphuric acid manufacture there was an actual increase in the proportion of the acid which escaped to the acid produced. The year 1888 shows a better record. In every single item recorded there is a distinct advance over the record of either 1887 or 1886. The improvement is most marked in the class of manure works where the proportion of noisome gas which escapes has been reduced by over 20 per cent. as compared with last year, the last year itself showing an improvement on the year before. An improvement less marked but still important is recorded in the manufacture of hydrochloric and sulphuric acids, and the remaining items, if differing only slightly from the results of previous years, at least show movement in the right direction. This is so far very satisfactory; but it is at least equally apparent from the report that the duties of the inspector might with advantage be enlarged and his powers extended. This is especially the case in connexion with the production and emission of acrid smoke. There can be no doubt that the industrial community as a whole is chargeable with some slackness in this particular. Hygienic and economical considerations alike point to the use of smoke consuming furnaces as being the only proper appliances to use for almost all the purposes of combustion. Yet their employment is by no means so universal as it might be expected to be. To some extent the supineness of the manufacturers may perhaps be accounted for by a singular misconception to which Mr. Fletcher calls attention. He states that it has been asserted that black smoke ought not to be lightly dispensed with; for, that if the combustion in a furnace be so conducted as to prevent its appearance, carbon monoxide would probably be generated and the remedy be worse than the disease. In view of this theory he has, we think, done well to publish the copious analyses of chimney gases, which illustrate that part of his report which deals with this subject. These show in the clearest way that the view in question is entirely without foundation, or even the appearance of support, not only in chemical theory, but also in practice. The dreaded carbonic monoxide makes its appearance always in company with clouds of smoke. When the smoke is slight, the admixture of monoxide is small in corresponding proportion, and when the effluent gases are perfectly clear no admixture of monoxide is ever found. It may be hoped, therefore, that this mistake will receive from the present report its *coup de grâce*, and that the direction of public attention to this important matter will have the highly desirable effect of securing better management for furnaces. It is, as the inspector pointedly remarks, "by no means necessary that the public should suffer in health, in comfort, and in pocket by a continuance of the smoke nuisance." There is one other passage in this report which we note with great satisfaction—namely, that in which the prospect is held out of securing at no distant date the general adoption of methods of utilising alkali waste. The enormous quantities of this material which distigure the neighbourhood of Widnes and Runcorn are not only displeasing to the senses, they are also sources of direct and serious loss, for they represent useless accumulations of highly useful materials. The reason for their accumulation has been that the cost of extracting their contents has heretofore been so great as to render the process unremunerative. We hear now, however, of an operation which will rescue the sulphur certainly, and possibly make the residue available for the purposes of cement. Should this be successfully carried out, the benefit will not only be considerable, but, what is even more rare, complete and unalloyed.

THE PARIS UNIVERSAL EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT.)

The International Congress of Hygiene.

ON Wednesday, Aug. 7th, as announced in a previous letter, the members of the Congress were up betimes, so as to catch the special train destined to take them to Rheims. After a three hours' journey we reached the historic town. A number of brakes, vans, and carriages were waiting at the station, and we were conveyed some distance out of Rheims to view the sewage farm. This is quite a new institution, and only commenced to receive the sewage some four months ago. The town possesses 150 hectares, but can dispose, for irrigation purposes, of 500 hectares. This is amply sufficient, and when there is a storm, or when by some other cause there is more sewage than the soil under cultivation requires, the water may be thrown on some waste land. Thus the danger of flooding the ground is obviated and underground drains are not required. There is a pumping station to send some of the water up to the higher grounds, which reach an altitude of twenty metres. Unfortunately the chief utility of this sewage farm is to prevent the contamination of the river. It does not in any way solve the drainage problem. Rheims still drains into cesspools; the town has not water enough for waterclosets, but when the water-supply has been increased, then the existence of this sewage farm will enable the town to drain direct into its sewers. After duly investigating all these facts, the Congress was entertained at lunch at the Château des Maretz, which belongs to the company that has undertaken the management of the sewage

Digitized by Google

farm. The lunch was served in a magnificent avenue of trees. Of course, there were some excellent speeches, notably by the director of the company, the prefect of police, the Mayor of Rheims, Dr. Napias on behalf of the French, and Mr. Adolphe Smith, who was specially requested to return thanks by the Swiss, Turkish, Russian, American, and English delegations. Madame A. Tkatchef, doctor in medicine, spoke for the ladies, and the utmost enthusiasm prevailed. The Congress then visited the cathedral, the Pommery champagne cellars, and were again entertained, this time by the Municipality of Rheims, at a second lunch given in the Town Hall. Here more speeches were delivered. Those who participated in this pleasant journey will recognise that the study of serious subjects does not interfere with the spirit of mirth and the sense of enjoyment.

On the following day, Thursday, the Congress set to work again in good earnest. In Section 1, M. Delvaille (Bayonne) urged that the medical inspection of schools, as prescribed by the law of 1886, should be more rigorously applied, and that medical officers should be appointed for this purpose. Dr. Sevestre, of the Paris pauper children's hospital, urged that it was in its earliest manifestation that measles was most contagious, and that children suspected of this complaint should be kept away, but that the convalescents might be allowed to return earlier than was at present the custom. Dr. Layet (Bordeaux) related that, by exceptional severity towards the "suspect," they had avoided the necessity of closing schools, while Dr. Rochard insisted that the school teachers must be instructed in these matters. It was no use relying exclusively on the medical profession, for there were 28,000 communes in France which had no doctor. With regard to short-sightedness in schools, Dr. Motais (Angers) gave the results of investigation on 6700 children. He found that short-sightedness was much more frequent in Germany than in France, but that it was growing to an alarming extent in France. He was anxious to see the course of studies varied and children prevented from looking for too long a period at some near object.

In Section 5, Dr. Alméras (Mentone) read a paper on the Contagion of Consumption, in which he complained that delicate persons were afraid to visit winter resorts for fear of contracting phthisis. He therefore asked that hotel keepers should take rigorous measures to disinfect rooms which had been occupied by consumptive patients. At the present time hotel keepers generally charged £12 in case of death, under the pretext that the room had to be purified; but it was rarely, if ever, properly disinfected. He proposed that the ceiling, walls, &c. should be submitted to a pulverisation with a sublimated solution containing 2 of mercury per 1000 of water and 12 in 1000 of tartaric acid. When this was dry, then the same place should be similarly sprayed with a 1 per cent. solution of carbonate of soda. This would convert the sublimate into insoluble salts. This service of disinfection should be managed in winter health resorts by representatives of the public authority, and hotel keepers should receive written certificates from the municipalities that the work had been properly done. If this certificate could not be produced, strangers should refuse to hire the room or apartment.

Dr. de Valcour (Cannes) described three cases of scarlet fever following upon each other in the same room of an hotel where disinfection had not been practised, and called upon Mr. Adolphe Smith to describe the English law on the subject. After the Congress had heard this explanation, Senator Dr. Pacchiotti related how a lady belonging to an aristocratic and influential family was taken away by the police from an Italian hotel (though she was in a very grave condition, and subsequently died), so that she should not infect the hotel with the small-pox she had contracted. The Italian law had armed medical men with sufficient powers to see that proper precautions were taken. Dr. Felix (Bucharest), on the contrary, was loth to ask too much from the State, and more anxious to so educate the people as to make them spontaneously and willingly take the precautions judged necessary. At Bucharest they had a disinfecting stove, and he was surprised to note how many persons came of their own accord and asked to use it. The declaration of infectious diseases was not obligatory in Roumania, but the police had ample powers over hotels. A Swiss delegate explained that only in some cantons was a notification of disease obligatory. Disinfection in towns was easy, but difficult in country districts, though there were epidemics in villages as well as in towns. The section concluded that in each sanitary district a disinfecting service should be organised, and that the carding of bedding in the streets or squares of towns should be prevented.

Dr. Devillers brought forward a motion against fairs held in large towns. He related that in 1886, in the Belleville districts of Paris, small-pox broke out immediately after such a fair, and in houses that faced the street where it was held. This present year, it had been noted that there were six times as many cases of scarlet fever near one of these fairs as in other parts of Paris. In some provincial towns similar observations had been made. Apart from epidemic diseases accidents sometimes occurred, and the noise was most distressing to many persons, especially to invalids. Some speakers objected, on the other hand, that the special tax levied on these booths provided money for the elementary schools; nevertheless the section voted that such fairs should be held in open spaces outside large towns, and not in the streets.

Dr. Martin now read a learned dissertation on the condition of French sanitary legislation. He lamented that there was no law against infection. Theoretically the mayors had considerable powers, but as they could not act without funds, and could not obtain funds without a vote from the municipal councils, their powers were rather nominal than real, especially in cases of emergency. Nor had the mayors received any support from the higher Courts of Appeal. For instance, during the cholera epidemic of 1885, the Mayor of Caen had suppressed a cesspool which caused a great nuisance and contaminated the subsoil. On appeal, the Higher Court, while recognising that it might have been necessary to suppress the cesspool, decided that the mayor had no right to prescribe how this should be done, but should have left the work to the discretion of the owner. Practically, if the sanitary authority had no right of supervision, it would mean that the work would not be done, or would be done badly. Again, at Toulon, during the cholera, a man refused to whitewash his room; the municipal authorities thereupon sent their agents to do the work. The owner appealed to the local police court, and this court approved the action of the municipality, but when taken up to the Court of Cassation, this tribunal refused to confirm the decision of the Toulon police magistrate. Municipalities, after such judgments, are afraid to act. The French penal code, it is true, gives the right to sue for damages, but to apply this in cases of contagion would be so unusual that no court would grant a verdict. Yet there are laws in France that are very severe, especially against foreign epidemics, such as cholera, plague, yellow fever, and in some cases penalties of one year's imprisonment and even a sentence of death can be applied; but the utter lack of national feeling renders it impossible to apply the legislation that does exist. The French sanitary law had been justly described as the "freedom of suicide." But no one had a right to create such infection in his own house, as it was likely to travel to the houses of others. It was not always the landlord who was to blame. Often a tenant would hire a stable or coach-house and convert it into a dwelling. The text of the law was extremely vague. What constituted an unwholesome dwelling should be clearly defined, and not left to the discretion of judges, who very often were absolutely ignorant as to the rules of health. Many courts by their verdicts had set forth that they did not consider a supply of water in a house a necessity. A high court had condemned a local bye-law ordering that houses should be supplied with water as an attack against individual liberty. The best method of action and of punishment was for the sanitary authority itself to effect the required improvements and charge the owner with the cost. Only this must be done promptly. As matters now stood legal decisions sometimes were obtained months after the nuisance had ceased to exist.

The discussion on this important subject was resumed in the afternoon sitting, when the difficulty of uniting the commissions of hygiene and similar bodies composed of men technically qualified to deal with such questions, but possessing at present only the right to give advice and no executive powers whatsoever, with the mayor, the prefect, or other authorities who could act, was very fully debated. The facts also that the mayor had to consider his electors, and if it was a fashionable resort he had to be very careful not to spread alarm, were obstacles to the stringent application of prophylactic measures. Two Bills had been before Parliament to create a sanitary law and a sanitary

Digitized by Google

authority. The project presented by M. Siegfried was countersigned by no less than fifty deputies belonging to all parties, and yet it had fallen through, such were the purely political preoccupations of the National Assembly. Dr. Treille (Deputy of Constantine in the French Parliament) remarked that as the sanitary services had been transferred from the Ministry of Commerce to the Ministry of the Interior, and were in the hands of a man on whom sanitary reformers might rely, we could look forward to considerable improvement. Parliament would not resist a project if its necessity was clearly demonstrated, but he would suggest that the Bill had better be first introduced into the Senate. Dr. Martin thought it was urgently necessary to alter the law of April 14th, 1850, which had rendered the law of 1789 inoperative. The Belgians, it had been seen, had availed themselves of the law of 1789, with the most admirable results so far as Brussels was concerned. Here 12,015 lives had been saved in fifteen years. Taking the one year 1886, there were 628 deaths less than the average. Estimating every life at the modest sum of 1000 francs, this represented a sum of 628,000 francs, and, as the Sanitary Bureau which had accomplished this result only cost 48,000 francs for the year, this was equal to an investment bearing an annual interest of 1400 per cent. On hearing these details the section burst into loud applause, and Dr. Janssens, the chief of the Brussels Sanitary Bureau, had to rise over and over again to bow his acknowledgments. After a few more observations from different speakers the section adjourned.

BURIAL REFORM.

THE returns obtained from the London cemeteries combine to furnish a most valuable document to all concerned in the work of burial reform. They were primarily moved for by a deputation from the Church of England Burial Reform Association, which also obtained the consent of Mr. Byrom Reed to ask for them officially in the House of Commons. The full significance of these returns will be made most apparent by placing the number of burials and the number of acres in each cemetery in juxtaposition.

* Including 10,000 stillborn infants.

Now it has been admitted authoritatively that in a well-conducted cemetery 1000 graves per acre can be made without any undue crowding, and graves may contain four, five, six, or more bodies, according to their depths. It must be evident from the preceding figures that there must have been the most frightful overcrowding in some of these cemeteries, and it is clearly imperative on the authorities to endeavour to prevent this in future. A certain standard number of graves in each acre should be allowed, and no excess permitted, while the number of bodies in each grave and the depth of the latter should be strictly limited.

THE INGHAM INFIRMARY, SOUTH SHIELDS.—The recent annual report, the sixteenth, records the continued satisfactory state of the institution. Financially, during the past year, there had been a general increase in the several usual sources of income. The medical statistics show that 193 in-patients and 1536 out-patients had been treated, that the casual cases at the dispensary numbered 5165, and 498 accidents were tended as out-patients.

THE PRIVY COUNCIL AND HYDROPHOBIA.

THE *London Gazette* of Tuesday states that on Monday last the Privy Council (present the Lord President and Viscount Lewisham) made an Order in Council with regard to rabies. The order recites that by the Contagious Diseases (Animals) Act of 1878 (amended in 1886) it is enacted that every local authority shall execute and enforce that Act and every Order of Council relating thereto, and that where a local authority fails the Privy Council may empower a person named in an order to enforce the provisions; that on July 9th last the Privy Council made the rabies order, which was to take effect from the 31st of that month, and that the order was to apply in the City of London and the Metropolitan Police district; that the local authority of the county of London (included in the Metropolitan Police district) is the London County Council; and that the said Council have failed to execute and enforce within the district the provisions of the rabies order. Therefore the Privy Council, in exercise of the powers vested in them, announce that Major John Trenchard Tennant, Chief Travelling Inspector of the Privy Council, is empowered to execute and enforce the rabies order or to procure the execution and enforcement thereof within the said district.

AMENDMENT OF THE CORONERS ACT.

THE following is a copy of a memorial sent to the twenty-eight large corporations, asking their agreement and support by similar memorial. Afterwards the memorial is to be forwarded, as soon as arrangements are completed, to the Local Government Board.

To the Right Honourable the Local Government Board, Whitehall, London.

The humble memorial of the Mayor, Aldermen, and Burgesses of the borough of Kingston-upon-Hull sheweth—

1. That your memorialists are the urban sanitary authority within and for the said borough, and, as such, the local authority for carrying out the provisions of the Public Health Act, 1875. Your memorialists are also the municipal authority having a separate court of quarter-sessions, and by the Municipal Corporations Act, 1882, have the right and power to appoint a coroner for the borough.

2. That an Act was passed in the session of 1887 which is known by the short title of the Coroners Act, 1887, which Act, in your memorialists' opinion, should be amended and altered, and your right honourable board is respectfully desired to introduce a Bill to amend certain of the provisions of the said Act of 1887, experience having shown the Act to be in many respects defective and insufficient, and to make further provision in relation thereto, more particularly the following:—

Your memorialists are advised and believe that section 4, subsection 1, should be altered so as to provide for the identification of the body by one or more competent witnesses before the coroner and the jury. The obsolete act of "viewing the body" by the jury, the intrusion of whom into a home rendered sacred by extraordinary grief and trouble, is unnecessary. It is offensive often to the jurymen, as well as to the relatives of the deceased, and raises a prejudice against thorough inquiry into the cause of death, because of the public excitement created in the neighbourhood.

3. That in most cases of inquests the inquiry takes place in Hull on premises belonging to licensed victuallers, commonly known as licensed premises, which, in your memorialists' opinion, should be prohibited, and, instead thereof, the urban sanitary authority should be compelled to provide and maintain proper and suitable places for the holding of such inquiries. If the useless act of "viewing the body" by strange jurymen be abolished, the necessity for holding the inquiry in the neighbourhood of the residence of the deceased would not exist. The removal of the coroner's court from the unwholesome surroundings of a room in a public house to a court house at the town hall, or other centrally situated premises, would promote the dignity of the inquiry and lead to increased efficiency. Nothing can be more repugnant to bereaved relatives than to have their natural sufferings accentuated by being the objects of what often proves to be unjust suspicions, exhibited to the gaze of persons surrounding a public-house bar. The structural arrangements of most public houses are unsuitable for holding public inquests, when it not infrequently happens that necessary witnesses have to arrange themselves, perhaps for the first time in their lives, in smoke rooms and dram shops, or stand upon the staircase, awaiting their summons, when such an inquiry ought to be held in a place and at a court befitting the solemnities and decencies of the occasion.

4. That in all urban sanitary districts the coroner may provide himself with a medical gentleman to act with him on such inquiries as he may deem it necessary in the capacity of assessor, and that the person to act in such capacity shall be a registered medical practitioner, appointed on such terms as may be considered necessary.

5. That in all urban sanitary districts, when a death is reported to the coroner the cause of which is not certified by any registered medical practitioner he may seek the professional assistance of any registered medical practitioner for the purpose of guiding him in his decision as to whether it may be necessary or not to hold an inquest. Such a professional opinion, from observation during life or otherwise, can in many cases render the cost and anxiety of a public inquiry unnecessary.

6. That your memorialists consider the present method of granting

Digitized by Google

orders for the burial of bodies where no certificate of death is given is highly unsatisfactory and open to grave objections, and that such be amended. In practice the coroner, after inquiries, gives an order for burial, upon which is not stated the cause which has led him to grant such order, and the Registrar of Deaths, upon the production of such order, makes further inquiries for the purpose of registration, often arriving at a totally different opinion as to the cause of death to that of the coroner. This often causes to the relatives of the deceased great annoyance and pain, and leads to grave errors appearing in the return of the Registrar-General.

Your memorialists, therefore, humbly pray that your right honourable Board may be pleased to introduce a Bill amending the Coroners Act, 1887, in the manner hereinbefore set forth.

And your memorialists will ever pray, &c.

The adoption of the propositions embodied in the above memorial have from time to time been advocated in THE LANCET. We heartily endorse the prayer of the memorialists, and trust that the matter will be taken up by the profession generally, so that additional weight may be given to the petition, and thus the chances of the introduction of a Bill into Parliament be enhanced.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Liverpool.—This city, notwithstanding all the difficulties that have to be still contended with, affords a striking example of what can be done by sanitary measures; indeed, the death-rate for 1888—namely, 20·3 per 1000 of the population—is only one-half what it was forty years ago. Amongst the present needs, Dr. Stopford Taylor adverts especially to the necessity of making further provision for the isolation of infectious patients, if Liverpool, with its 600,000 people, is to be rendered at all safe in this matter. A great reduction has taken place in the deaths from typhus. In 1871 they were 568 in number, since which date they have steadily diminished, until last year they only numbered 36. In all, 5987 cases of infectious disease came under the notice of the medical officer of health, and of these 1003 were removed to hospital, either as paupers or in connexion with the provision made by the Town Council. The total number of infected articles which were disinfected was 25,454, and 1713 houses were dealt with in the same way. Improvements are steadily in progress as regards the common lodging-houses, and 765 sublet houses are also placed on the register; and, in a number of instances, fines were imposed for breach of the bye-laws. A vast amount of current work is included in the tabular matter which is appended to the report, and which relates to the duties performed in the various departments which come directly or indirectly under the supervision of the medical officer of health.

Bristol Urban District.—Dr D. S. Davies, in giving a somewhat complete account of the sanitary circumstances of Bristol, reminds the authority that private wells still remain within their limits, and he adverts to the danger of drawing a supply from a soil the surface of which is necessarily contaminated by the life conditions of over 220,000 people. To us, it seems almost incredible that such a condition of things can have remained to the present day. The sewers of Bristol remain without any special provision for ventilation, and it is only as regards new houses that efficient trapping of drains from sewers and a through current of air are required as regards the house drains. Exhaustive inquiry into such a system of sewerage might help to solve the question as to the extent to which it is requisite to ventilate public sewers, and as to the best manner of carrying any such ventilation into effect. Revision of the local bye-laws is evidently much needed in some respects; thus we learn that Bristol has no requirement as to a damp course in newly erected houses, and that conditions highly detrimental to health are the result. Very definite advice is given by Dr. Davies as to the present insufficient accommodation for the isolation of the infectious sick, and as to the unsuitability of such accommodation as does exist for the proper separation of a sufficient number of diseases; indeed, for nine months the hospitals were perforce closed against any but cases of small-pox—a condition of things that should not be liable to occur within the area of a sanitary authority such as that for Bristol. Amongst the other more important mattters dealt with in an exhaustive report are the questions of a public abattoir, the provision of a destructor for better dealing with ashes and house refuse, inspection of dairies, the making of bye-laws for regulating houses occupied by more than one family, and the provision of a steam washing-machine supplementary to the steam disinfector. The corrected death-rate for 1888 would appear to have been 17·4 per 1000. A separate report is given as to the port sanitary district, in which such work is carried on as regards the inspection of shipping as must tend steadily to secure great improvement in the sanitary circumstances which affect a floating population estimated at nearly 15,000 persons.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 4838 births and 3437 deaths were registered during the week ending Aug. 10th. The annual rate of mortality in these towns, which had been 21·0 and 20·5 per 1000 in the preceding two weeks, further declined to 18·8 last week. During the first six weeks of the current quarter the death-rate in these towns averaged 20·1 per 1000, and was 0·5 below the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 13·9 in Oldham, 14·3 in Derby, 15·7 in Bristol, and 16·4 in London. The rates in the other towns ranged upwards to 28·4 in Sunderland, 30·8 in Newcastle-upon-Tyne, 31·4 in Plymouth, and 34·6 in Preston. The deaths referred to the principal zymotic diseases in these towns, which had declined from 1018 to 893 in the preceding three weeks, further fell to 785; 548 resulted from diarrhœa, 60 from whooping-cough, 58 from measles, 52 from scarlet fever, 38 from diphtheria, 29 from "fever" (principally enteric), and not one from small-pox. These zymotic diseases caused the lowest death-rates last week in Halifax, Cardiff, Bristol, and Huddersfield, and the highest rates in Sunderland, Plymouth, Sheffield, and Preston. The greatest mortality from diarrhœa occurred in Sunderland, Norwich, Leicester, Sheffield, and Preston; from measles in Wolverhampton, Halifax, Hull, Newcastle-upon-Tyne, and Preston; from scarlet fever in Sheffield, Huddersfield, and Plymouth; from whooping-cough in Newcastle-upon-Tyne and Portsmouth; and from "fever" in Preston. The deaths from diphtheria included 28 in London, 2 in Plymouth, 2 in Birmingham, and 2 in Manchester. Small-pox caused no death in any of the twenty-eight great towns; and no small-pox patient was under treatment at the end of the week either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and London Fever Hospitals at the end of last week was 779, against numbers increasing in the preceding six weeks from 559 to 727; 98 cases were admitted to these hospitals during the week, against numbers increasing from 33 to 124 in the previous eight weeks. The deaths referred to diseases of the respiratory organs in London, which had risen from 141 to 182 in the preceding three weeks, declined last week to 149, and were 40 below the corrected average. The causes of 81, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Norwich, Wolverhampton, Bradford, Sunderland, and in five other smaller towns. The largest proportions of uncertified deaths were registered in Manchester, Nottingham, Blackburn, Liverpool, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·9 and 18·3 per 1000 in the preceding two weeks, further rose to 18·6 in the week ending August 10th; this rate was slightly below the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns ranged last week from 15·0 in Edinburgh, in Aberdeen, and in Leith, to 21·0 in Glasgow and 30·8 in Paisley. The 475 deaths in the eight towns showed an increase of 7 upon the number in the previous week, and included 57 which were referred to diarrhœa, 24 to

Digitized by Google

whooping-cough, 10 to measles, 7 to diphtheria, 7 to "fever," 2 to scarlet fever, and not one to small-pox; in all, 107 deaths resulted from these principal zymotic diseases, against 95 and 77 in the previous two weeks. These 107 deaths were equal to an annual rate of 4·2 per 1000, which almost corresponded with the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of diarrhœa, which had been 41 and 39 in the preceding two weeks, rose last week to 57, and exceeded by 39 the number returned in the corresponding week of last year; 23 occurred in Glasgow, 11 in Dundee, and 11 in Paisley. The deaths referred to whooping-cough, which had been 21 and 15 in the previous two weeks, rose again last week to 24, and included 14 in Glasgow, 5 in Paisley, and 4 in Dundee. The 10 deaths from measles exceeded by 2 the number in the preceding week; 4 occurred in Edinburgh and 3 in Leith. The 7 fatal cases of diphtheria included 3 in Glasgow and 2 in Edinburgh. The 7 deaths referred to "fever" corresponded with the number in the preceding week, and included 5 in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 55 and 60 in the preceding two weeks, were again 60 last week, and exceeded by 11 the number returned in the corresponding week of last year. The causes of 47, or nearly 10 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·8 and 20·7 per 1000 in the preceding two weeks, rose again to 24·8 in the week ending Aug. 10th. During the first six weeks of the current quarter the death-rate in the city averaged 23·7 per 1000, the mean rate during the same period being 17·9 in London and 16·2 in Edinburgh. The 168 deaths in Dublin showed an increase of 28 upon the number in the preceding week; they included 17 which were referred to diarrhœa, 4 to whooping-cough, 3 to measles, 1 to "fever," and not one either to small-pox, scarlet fever, or diphtheria. Thus the deaths from these principal zymotic diseases, which had declined from 25 to 15 in the preceding three weeks, rose again to 25 last week; they were equal to an annual rate of 3·7 per 1000, the rate from the same diseases being 3·1 in London and 2·9 in Edinburgh. The deaths referred to diarrhœa, which had fallen in the three previous weeks from 13 to 8, rose again to 17 last week. The three fatal cases of measles showed a slight decline from those recorded in recent weeks, while the 4 deaths referred to whooping-cough exceeded those returned in any recent week. The deaths of infants showed a slight decline from those in the previous week, while those of elderly persons showed a marked increase. Eight inquest cases and 4 deaths from violence were registered; and 46, or nearly a third, of the deaths occurred in public institutions. The causes of 18, or more than 10 per cent., of the deaths in the city were not certified.

THE SERVICES.

ARMY MEDICAL STAFF. — Surgeon-Major Nathaniel Alcock is granted retired pay (dated Aug. 14th, 1889); Surgeon Benjamin Allen Maturin, from half pay, to be Surgeon, vice George Scott Tate, M.D., deceased (dated July 26th, 1889).

ARMY MEDICAL RESERVE OF OFFICERS. — Surgeon William Milsted Harmer, F.R.C.P. Ed., 2nd Volunteer Battalion, the Buffs (East Kent) Regiment, to be Surgeon, ranking as Captain (dated Aug. 14th, 1889); Surgeon-Major John Prior Purvis resigns his commission (dated Aug. 14th, 1889).

HONOURABLE ARTILLERY COMPANY OF LONDON. — Richard James Reece, late Surgeon, Volunteer Medical Staff Corps, to be Surgeon (dated Aug. 10th, 1889).

VOLUNTEER CORPS. — *Artillery:* 1st Fifeshire: The undermentioned Acting Surgeons to be Surgeons: R. B. Graham (dated Aug. 10th, 1889); S. Linton, M.B. (dated Aug. 10th, 1889).—1st Caithness: Surgeon-Major (ranking as Lieutenant-Colonel) T. H. Rutherford, M.D., resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the Corps on his retirement (dated Aug. 10th, 1889).—*Rifle:* 1st Volunteer Battalion, the Lincolnshire Regiment: Honorary Assistant Surgeon J. W. Hembrough resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement (dated Aug. 10th, 1889).—2nd Volunteer Battalion, the East Yorkshire Regiment: Acting Surgeon A. F. A. Fairweather, M.D., to be Surgeon (dated Aug. 10th, 1889).—2nd Volunteer Battalion, the Royal Scots Fusiliers: Acting Surgeon J. R. Watt, M.B., resigns his appointment (dated Aug. 10th, 1889).—5th (Deeside Highland) Volunteer Battalion, the Gordon Highlanders: Acting Surgeon D. M. Arthur resigns his appointment (dated Aug. 10th, 1889).—1st Dumbartonshire: Thomas Fauset Macdonald, M.B., to be Acting Surgeon (dated Aug. 10th, 1889).

VOLUNTEER MEDICAL STAFF.—The London Division: Surgeon Richard James Reece resigns his commission (dated Aug. 10th, 1889).

Correspondence.

"Audi alteram partem."

VACCINATION AND INFANTILE SYPHILIS.

To the Editors of THE LANCET.

SIRS, — The letter in your last week's issue by Dr. J. C. McVail, on the statistical proof that infantile syphilis has not increased owing to vaccination, raises a point as between himself and me which is, as he truly says, of small moment. My conclusion from the Scottish statistics was the same as his own, and happened to be published before his; only, it was not extended at so great length in my book as in his, and so it serves as a "valuable indication" of the slender basis upon which I rest a conclusion, and of the small amount of demonstration which satisfies me in a different matter altogether—namely, in my long historical account of the rise of Jenner's doctrine and practice, and of its acceptance at home and abroad. As Dr. McVail announces in his letter that he is now engaged in criticising my book, "Jenner and Vaccination," in an Edinburgh journal, I am at a loss to understand why he should ask your readers to judge of it by a mere "indication," derived from a source outside the book itself. The valuable indication is intended, I suppose, to be only provisional, and it is for the more particular benefit of a supposed reader of my book "who has not the opportunity of consulting the evidence at first hand." What difference would it make if this reader had before him all the original authorities whom I have either quoted in their own words or referred to in three or four hundred notes, or any other contemporary authorities which may be known to him, but are not known to me? Would the reader find my citations to be garbled, or the passages referred to in the notes insufficient to bear out the respective statements in the text? or would he find from his first-hand search through old journals, reports, pamphlets, and books, that I had taken what I ought to have left, and had left what I ought to have taken? If Dr. McVail be himself a reader who has consulted the evidence at first hand, he will have no difficulty in giving a reply to my question, which will be more useful both to me and to the supposed helpless reader than the vague and comprehensive innuendo which he thinks to get off with. Meanwhile, I have to deal only with his "valuable indication" of my scrappy method of proof. It so happens that I used the same argument against the connexion of infantile syphilis with vaccination which Dr. McVail used very soon after and independently. Anyone who happens to have his attention directed to the Scottish mortality returns will see that the mode of entries of the deaths of infants in their first year — namely, in separate columns for the first quarter of the year, the second quarter, and the second half respectively—is well calculated to throw light upon the alleged connexion of syphilis with vaccination, inasmuch as the operation need not be done in Scotland until six months from birth, and is, I am informed, in nearly all cases of public vaccination deferred as long as the law allows. On extracting the figures under the head of syphilis for several years, the result was at once obvious to me, as it would be to anyone, that "considerably more than half the deaths from syphilis under the age of one belong to the first three months of infancy." That appeared to me to be "a significant fact," which had not been used in the controversy before, and a fact which confirmed my pathological argument about the congenital type

Digitized by Google

of infantile syphilis, and about the causes other than vaccination to which its increase was due. It appears, however, that in thus arguing from the Scottish statistics, I have argued "on a slender basis." Dr. McVail argues to precisely the same effect, only he labours the point in a much more impressive, not to say pedantic, manner. He transcribes the figures from the Scottish reports into his book, whereas I transcribed them only into my note-book. He then proceeds to extend the argument as a mathematical certainty and to stretch it so as to cover the very margins of probability, in a way which no one but a hardened statistician would ever think of doing. My failure (or refusal) to do the like is his "valuable indication" of my slender basis of proof and small amount of demonstration. By quoting the first words of a sentence in my letter of Dec. 1st, and leaving out the principal part of the sentence, he makes the basis of my argument about infantile syphilis to appear much more slender than it was in fact. I shall continue the sentence from the point where Dr. McVail dropped it: "and it [the statistical argument] formed only one small part of a general exposition of the pathology of infantile syphilis as congenital syphilis." The "indication" of my scrappy method of proof might have been less valuable, the basis might have appeared less slender, if my statistical argument had been reproduced in its proper connexion, as corroborating a much more elaborate argument from the pathological side of the case. Statistical abstractions are well enough in their way, although Dr. McVail seems to me to rely too exclusively upon them and to drive his inferences much too far in the direction of mathematical certainty. As he has thought fit to raise the point as to what is and what is not a "slender basis" for the proof that infantile syphilis has not increased owing to vaccination, I willingly submit my evidence for comparison with his. The former traces the increase of infantile syphilis positively to certain influences in modern industrial life, which tell unfavourably upon the nutrient function of the placenta, and so add to the amount of congenital disease all round; while, negatively, it excludes vaccination as the cause of the progressive increase by my original argument from the Scottish tables, which is stated correctly, although in the briefest possible manner. Dr. McVail's evidence is the same statistical argument, worked out independently by himself and thrown into the form of a quasi-mathematical demonstration, that the increase of syphilis in infants is not due to vaccination, whatever else it may be due to.

If the doctor has anything of a general kind to deliver on the relative value of probable and other evidence, and on the nature of proof, I hope he will table his contribution in the usual way. He will find me an attentive reader, the more so that I have myself essayed the theme, under a concrete guise, in an article published in one of the magazines for March last. These questions of sufficient evidence and of the proof which amounts to certitude are very old, and have received different answers from different sides, according to temperament and training. We have had an illustration in this country during the last few days. There are practised reasoners and eminently practical men who prefer to rely, for legitimate proof sufficient to yield certitude, upon various cumulating and converging probabilities, brought together with due diligence, and of course with close scrutiny, as regards all matters of fact. Dr. McVail will find that his objection to a "slender basis" of proof, or to a "small amount of demonstration," is not, as he supposes, an affair of the peculiarities or shortcomings of an individual writer, but a fundamental question of method, which has been a good deal debated at one time or another, and is clearly in need of being debated still farther.

I am, Sirs, your obedient servant,

Aug. 12th, 1889. C. CREIGHTON.

DIPHTHERIA AND ITS TREATMENT.

To the Editors of THE LANCET.

SIRS,—It is nearly two years since you did me the favour to place my views before the profession upon the "pathology and treatment of septic diseases." I am equally anxious that you should allow me to return to the subject, especially in relation to the treatment of diphtheria, when one reads in one of our daily papers (the *Morning Post*), in a leading article wherein it is stated a short time since that "diphtheria is a most formidable and fatal disease; at present its origin, its mode of spread, and the best method of treating it are alike subjects of dispute among the medical profession." I think, Sirs, we can scarcely admit that the origin of diphtheria and its mode of spread are still *sub judice*, as the medical profession have, during the past two or three years, agreed that one of the chief causes is aerial infection. Some atmospheres have been microscopically proved to contain millions of micro-organisms floating in them, especially in low, damp situations, badly drained, and overcrowded localities. Milk is another source, from cows drinking from stagnant ponds which in some seasons of the year are teeming with micro-organisms, producing in some cases diphtheria and at other times scarlatina, according to the specific character of the germs taken in, attacking children and others under states of low vitality. We also know that the specific contagium of diphtheria has infected animals and communicated the disease to human beings, as it has been seen in cats, fowls, and pigeons, as also from horses under the influence of strangles.

We have reason to believe that micro-organisms are more rife and proliferous in the atmosphere of late, as we find insect life generally is more prolific and pestilential to vegetable life. Undoubtedly diphtheria has of late years assumed a more virulent type from the above-stated reasons. The opinion now prevalent is that the throat is the primary seat of the disease, and the general poisoning of the system is due to the rapid absorption and infection from this source. The exudative inflammation caused by these microbes upon the membrane brings about a gelatinous or tougher kind of deposit looking like a patch of washleather, and in this membranous exudation are these micro-organisms found secreted. An important feature to be noted in diphtheria is, in many cases, the painless character of the throat affection, and thus frequently not attended to in the early stage. In one of our largest hospitals two house surgeons have died from the disease from inattention to first symptoms; they were not attended to until the system was saturated with these microbes.

Then, as to the treatment of diphtheria, I am grieved to admit there is a divergence of opinion, although it is generally agreed upon that the antiseptic plan is the most natural as well as successful; but upon the precise method of its adoption there are various modes of carrying it out. Fashion has much to do with it—e.g., some adopt the spray application to the throat; others have topical applications, mopping the diseased mass with boracic acid &c., with variable success; while I hold it is absolutely essential to select a very decided microbicide fluid, applied with a camel's hair brush, and the whole, or as much as the patient can tolerate, of the morbid deposit *brushed off and removed at each visit*, thus arresting the circulation of these germs from the surrounding atmosphere of the patient, so important for those in attendance.

Some men of standing and experience have objected to *irritating* the patient by applications to the throat. After thirty-five years of active practice, I invariably commenced by attacking the throat with a strong solution of nitrate of silver (one drachm to the ounce), and in many cases removing the whole of the deposit upon my first visit, thus materially cutting short the progress of the disease. I never had occasion to regret my applications; *mais, au contraire*, I used to continue daily applications so long as any deposit could be seen. I must admit it used to momentarily distress the patient. The liquor sodæ chloratæ is another excellent microbicide for application with a camel's-hair brush. As it is known that these microbes multiply with frightful rapidity when once within the body, it is important to adopt energetic measures for their destruction and extermination *quam primum*. To this end I would recommend following up the application to the throat by a mustard emetic, so as to dislodge and evacuate these micro-organisms from the stomach, œsophagus, and fauces, the oil of mustard, according to MM. Cornil and Babes, being an excellent microbicide. In half an hour, or as soon as the system had recovered from the effects of the emetic, I should give a dose of the liquor hyd. perchloridi in a little strong peppermint water, peppermint being another decided antiseptic. This dose might be repeated in another hour, and in about half an hour after this second dose of the liquor hyd. perchloridi a dessertspoonful or a medium dose of castor oil in peppermint water as an effectual evacuant. Having cleansed the entire gastro-enteric canal of these pernicious atoms, those that have entered the circulation must be disposed of in the way that Dame Nature is wont to do—i.e., by the emunctories of the body aiding her in various

Digitized by Google

ways—viz., by keeping the patient warm in bed in an airy apartment, administering saline diaphoretics with chlorate of potash, aided by nutritious and unstimulating diet—e.g., pure milk, beef-tea, barley-water, and cocoatina. This is all that is necessary for two or three days, especially while febrile symptoms are present. Tonics and stimulants in the early stages should not be given.

Under the above treatment the system will very soon manifest reaction by ridding itself of the *materies morbi* under which it is so distressed. Doubtless there are cases which will require a course of ferruginous tonics for some little time, as it is well known these animalcues lessen the red corpuscles of the blood. In the administration of the liquor hyd. perchloridi, we must bear in mind we have a special microbicide. According to Cornil and Babes 1 in 20,000 will kill the spores in ten minutes. For a more detailed report of diphtheria, *vide* THE LANCET, Aug. 20th, 1887.

I believe in those cases where the urine is albuminous, it is owing to the retention within the body of the kidneys of a multitudinous host of the microbes, which those organs are endeavouring to eliminate, as we find upon the cessation of the albuminuria the patient's alarming symptoms are ameliorated. After death the blood has been found loaded with micrococci as well as the internal organs, particularly the kidneys, where they were found in numerous thrombi or in balls.

Upon inquiry at two of our largest hospitals a short time since upon their general treatment of diphtheria, I was sorry to learn that it was upon the stimulating and tonic plan *ab initio*, with poor results, and not upon the antiseptic and eliminative. I am, Sirs, yours faithfully,

Hanwell, August, 1889. EMANUEL MAY, M.D.

P.S.—I feel that I ought to mention that during an active practice of thirty-five years I only lost two patients with diphtheria, and each of these had been ill two or three days when I was called in to see them, and found that in each case the disease had travelled into the windpipe.

THE NOTIFICATION OF INFECTIOUS DISEASES BILL.

To the Editors of THE LANCET.

SIRS,—Permit me to ask, through the medium of your columns, has the profession fully considered this Bill, which is being pushed through Parliament with breathless speed at the fag end of the session? The sanction of the public would appear to be taken for granted in such a matter, though I am not aware of a single public meeting having been held to promote the Bill, and petitions in its favour have not required more than a single person to carry them. Has the great body of general practitioners considered the powers and the responsibilities which it is sought to confer? That it has the cordial approval of enthusiastic officials who are prepared to banish every ill and secure immortality for mankind, if the Legislature would only invest them with plenary powers, I have no doubt; but what about the rank and file upon whom the *onus*, or, as some say, the *stigma*, of carrying out the notification will fall? That a person labouring under an infectious disease may by exposure or inadequate isolation at home become a public nuisance is self-evident; that he is in most cases a nuisance in spite of himself, involuntarily, is equally true; how, then, shall he be dealt with? *Salus populi suprema lex* is a maxim at once as obvious and as useless as maxims are apt to be. Medicine, as a recent judicial utterance reminds us, is far from being an exact science, and so far does not lend itself readily to legislation. The Bill I understand is designed to deal with cholera, diphtheria, croup, small-pox, erysipelas, scarlet fever, typhus, typhoid, relapsing, and puerperal fevers. On the outbreak of any one of these the nearest relative or the occupier of the house is to acquaint the medical officer of health of the fact, and the medical attendant is also to send a certificate to the medical officer stating the infectious disease from which the patient is suffering. By section 124 of the Public Health Act, 1875, when the accommodation of the patient is not deemed satisfactory he may be compulsorily removed to any "hospital or place" which is deemed "suitable for the reception of the sick." The notification is to be compulsory for London; optional—at any rate at first—elsewhere.

Now it would be affectation to pretend that diagnosis in the case of many of the enumerated diseases is by any means invariably easy—nay, it is not always possible. Mistakes have occurred, and history may repeat itself, and every mistake means an unpleasant experience for the patient. Then, again, Dr. John Harley, in April this year, warned the College of Physicians that in the case of scarlet fever he had "been endeavouring all his medical life to obtain proof of its contagiousness, yet had failed to find it, but he had acquired some evidence to the contrary." Who knows but that such an utterance within such precincts may not have largely influenced medical opinion in the country, and what is then to become of the notification of that disease which other authorities hold to be the most infectious of all? Again, suppose under the new Bill and the old Act the following very possible sequence of events: Compulsory notification of, say, typhoid; the surroundings are deemed unsatisfactory and to hospital the patient goes. To obviate escape compulsory detention follows as a matter of course, and grim comfort is to be found in the reflection that

> "Stone walls do not a prison make,
> Nor iron bars a cage";

for in future its place will be supplied by a "hospital or place suitable for the reception of the sick." Compulsory treatment goes without saying—that is to say, the segregated patient has no longer the choice of his medical attendant, and there is hardly any line of treatment in typhoid which would not be vigorously assailed as useless and dangerous by some medical authority or other. This by no means exhausts the difficulties which will be certain to arise. Some may ask whether the adoption of the system in various places has been followed by uniformly good results, and the answer must be in the negative. Others will doubtless inquire whether it is not the sound that should make way for the sufferer rather than the risks of the sick be increased to save the whole. Questions of humanity will arise, and men will want to know the reason why a child with croup is to be robbed of parental care, and the puerperal woman torn from her natural protector, in the hour of sickness. To these a sneer of sentimentality will be an inadequate and ill-conceived retort. It has been well said "a sick body is better than a hard heart," and there are still higher motives to action in human nature than a funk of infection.

Lastly, medical men are justly fearful lest the notifying certificate required of them will operate detrimentally upon the relations between them and their patients, which they regard more highly than the sop which is offered them in the shape of a fee for such betrayal—viz., thirty pieces of—copper!

These, Sirs, are some of the difficulties I have heard raised. There are doubtless others, and there is much to be said on the other side no doubt; but if so, why this haste for ill-considered legislation upon an inadequately discussed and thorny topic?

I am, Sirs, yours truly,

W. J. COLLINS, M.S., M.D., B.Sc. Lond.

Regent's-park, Aug. 11th, 1889.

To the Editors of THE LANCET.

SIRS,—In your last issue Mr. Biddle refers to Bradford in connexion with the single system of notification of infectious disease. In the great majority of cases the notification is sent by the medical practitioner in a stamped envelope provided for the purpose, and addressed to the medical officer of health. From the readiness with which the medical men of Bradford take this duty upon themselves, I infer that they would find no hardship in the dual system of notification. I am, Sirs, yours faithfully,

Bradford, Aug. 12th, 1889. JAS. MCLINTOCK.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Corporation and Typhoid Fever, &c.

IT would appear that there is certainly a real desire on the part of our local parliament to do something to wipe away the disgrace of being the city with the highest mortality in the kingdom. The Unhealthy Dwellings Committee have a herculean task before them in their attempts to abolish the worst of the wretched tenements in which so many of the poor are huddled. At the last meeting of the Council it was stated that our new officer of health has been authorised to visit those large towns where similar

Digitized by Google

efforts have been made, that the experience gained there might be utilised in Manchester. Another important step was sanctioned—i.e., that all cases of typhoid fever not having proper accommodation at home should be removed to the Infirmary Fever Hospital. To many it will no doubt appear late in the day for such a decision to be arrived at, but hitherto very few of these cases have been removed owing to the expense. The corporation at the present time pay large sums annually to the infirmary for the treatment of scarlet fever and small-pox, and from the report recently published at the annual meeting of the subscribers to the infirmary it would appear that no less a sum than £3000 was carried as profit to the infirmary funds from the receipts at the Fever Hospital, whilst during the past six years upwards of £17,700 has been made in excess of expenditure by the treatment of fever patients sent in by the surrounding health authorities.

The Sanitary Association.

This association has always showed itself desirous of assisting and helping forward the work of sanitation, at times appearing too eager for progress to suit the more slowly moving wheels of the corporation health machinery. It is at present endeavouring to aid the movement of smoke abatement by forming a committee to bring before the public, by means of an exhibition or some other practical manner, the various appliances which are efficient in preventing the waste of fuel and terrible pollution of our atmosphere which is continually going on. A very influential list of names has already been secured, headed by the Duke of Westminster, the Bishops of Manchester and of Salford, Sir F. Douglas Galton, and many eminent sanitarians.

The Proposed Fever Hospital in Salford.

A stormy scene took place at the last meeting of the Salford Council over the proposed Fever Hospital. A letter has been received from the Local Government Board sanctioning the proposal to borrow £13,100 for a new Fever Hospital at Ladywell concerning which a lengthened inquiry was recently held. The opposition to the selected site is, however, still very strong, and a resolution was carried deferring the whole business, and a committee was formed to reconsider the subject. The grounds of opposition appear to be two: first, that the site is a very undesirable one; and, secondly, that arrangements might be come to with the Manchester Infirmary for the reception of Salford cases in the same way that Manchester patients are received. All small-pox cases from Salford already go there, and it seems that the Salford Corporation also claim some right to send patients there free of cost, having paid to the infirmary authorities more money than they ought to have done, to the extent of some £300.

Hulme Dispensary.

At the annual meeting of this dispensary a very gloomy account was given of its financial position, and the committee state that "a crisis has now arrived in the life of this institution, and unless substantial assistance be afforded the existence of the Hulme Dispensary is imperilled." In years gone by good work has been done by this institution, and more than one former member of its staff has been promoted to that of the Royal Infirmary. It has been in existence now more than twenty years, and when it commenced its work provident dispensaries were unknown, and the other charities did not extend their operations over so large a field as at the present time. Last year 4037 out-patients and 2725 home-patients were treated, but it is at least open to argument whether most of these could not be provided for by the other charities referred to.

Victoria University.

In the pass lists of the Faculty of Medicine just published it is stated that in the Preliminary Scientific 9 students passed in the first division (5 from Owens College, 3 from University College, and 1 from the Yorkshire College); in the second division, 23—i.e., 13 from Owens, 8 from University, and 2 from Yorkshire College. In the Intermediate M.B. and Ch.B., first division, 2 from Owens College; in the second division, 5 from Owens and 3 from University College. In the Final M.B. and Ch.B., Part I., 6 from Owens and 3 from University College. Part II., first division, 4 from Owens; in the second division, 9 from Owens and 1 from University. Seven candidates also passed for the diploma in Sanitary Science.

Manchester, Aug. 12th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

University of Durham Medical Degrees.

I HEAR that the coming examinations for the various medical degrees of the University of Durham, to be held at Newcastle, is likely to be the largest as regards candidates since the establishment of the University. Over seventy, I understand, have entered for the first M.B. The degrees for practitioners, and those for the diploma in Sanitary Science, will bring the number of candidates up to—if they do not exceed—one hundred. So that there can be no question that the Durham degrees are increasing in popularity with the profession.

Tynemouth as a Health-resort.

Dr. Charles Gibson has reprinted in pamphlet form an address which he gave in 1887, when president of the North of England Branch of the British Medical Association, pointing out the advantages of Tynemouth as a health-resort. There is no doubt that in its proper seasons Tynemouth has many advantages for suitable cases. For instance, in the latter part of summer, and as a rule throughout autumn, it is dry and bracing, but it should be avoided in winter in all pulmonary cases; while in the spring, from the coarseness of its atmosphere, which it has in common with all our north-eastern coast, it is not good for asthmatics and very bad for bronchial cases. It is right to mention, as Dr. Charles Gibson points out, that the zymotic death-rate is low, and the average death-rate for five years—viz., June, 1882, to June, 1886—was only 11·52 per 1000. Some improvements in the water-supply are however, I believe, still desirable in this popular Tyneside health-resort.

Tynemouth Infirmary.

On Saturday Earl Percy performed the opening ceremony of the new public infirmary for the borough of Tynemouth, the foundation-stone of which was laid in commemoration of Her Majesty's Jubilee on Jubilee day, when the institution took the name of the Victoria Jubilee Infirmary. The site of the building was generously given to the trustees by his Grace the Duke of Northumberland, and it occupies a commanding and convenient position. The building has the usual modern hospital conveniences, with male and female wards, besides separate children's and isolation wards. The operation room is well contrived, lighted from the top as well as the sides, to prevent shadows falling on the table.

Hospital Demonstration.

The annual Sunday hospital demonstration has taken place under favourable auspices, including good weather, at North Ormesby. The various friendly societies mustered in large numbers in the market place, and marched to the music of spirited bands to the lawn in front of the cottage hospital, where addresses were delivered by some of the local M.P.'s and other leading local men. The collection taken was, I understand, to be divided between the North Ormesby Cottage Hospital and the North Riding Infirmary at Middlesbrough.

Tees Port Sanitary Authority.

At the last meeting of the Tees Port Sanitary Authority it was reported that during the past month 215 vessels had been inspected, but all were found clean with two exceptions. There had not been a single case of infectious disease on any vessel during the month.

Newcastle-on-Tyne, Aug. 14th.

DUBLIN.

(FROM OUR OWN CORRESPONDENT.)

The Prevention of Cruelty to Children.

IN the Dublin Southern Police-court last week the mother and stepfather of a child were prosecuted for having unlawfully withheld sustenance from her. The charge was brought by the inspector of the English Society for the Prevention of Cruelty to Children, but as the Act did not apply to Ireland the case was brought under the ordinary provisions of the Vagrancy Act. The evidence showed a most revolting state of things. The unfor-

Digitized by Google

tunate child—whose age was really six years, though she appeared to be not more than three—was proved to have been greatly neglected by her inhuman parents, sometimes being left for ten hours without food. The magistrate sent both prisoners to gaol for three months with hard labour, being the full punishment the Act of Parliament allows.

Mercer's Hospital, Dublin.

Dr. Cosgrave has been elected by the medical staff visiting physician, in the room of Dr. Knight. The validity, however, of this election is, I learn, a matter of dispute. Dr. Cosgrave is one of the physicians to Simpson's Hospital, and is connected with the Carmichael School of Medicine.

Adelaide Hospital, Dublin.

In response to the appeal by the committee for funds to clear off the debt which exists, about 1000 guineas have already been received.

Sanitary Condition of Derry Gaol.

As allegations have been made as to the insanitary state of this prison, and that an inmate died from fever contracted within its walls, the General Prisons Board on Tuesday sent Dr. O'Farrell, medical officer of the board, to investigate the matter. It is satisfactory to learn that, after a close examination, the prison was found to be in a perfectly sanitary state.

The Dublin Barracks.

There are at present some fifteen cases of typhoid fever among the troops in garrison, fourteen being from the Royal Barracks. The sewerage at the latter is being overhauled, and the Richmond Barracks are to be redrained.

Dublin, Aug. 13th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Inheritance of Syphilis.

CONTINUING the consideration of this subject, so full of interest to every practising physician, Professor Fournier, having passed in review the various opinions advanced as to the etiology of this disease, and traced the several sources of heredity with so much preciseness to their origin (see THE LANCET of July 20th and Aug. 3rd), next discussed the *prognosis* as regards the child; and as at the outset he showed heredity to be more frequently paternal than maternal in its origin, he would now prove that the latter was much more disastrous to the offspring than the former. That this was so one might almost affirm *a priori*, for the influence of the father was exclusively one of fecundation, whereas the maternal influence was *plus* this—one that was actively sustained throughout the whole of gestation; and it was evident that the alteration in the health of the mother from her syphilis, constantly present in a state of active evolution, could rarely fail to reflect itself on the fœtus. But whatever the true explanation, there was no doubting the fact that heredity of maternal origin recoiled with deadly effect on the child. For instance, in twenty-eight pregnancies where the mothers alone were syphilitic, twenty-one, or 80 per cent., resulted in the destruction of the offspring. Where heredity was traceable to both parents, the results, as might well be surmised, were still more deadly. In this connexion he cited the striking case recorded by Diday, in which a syphilitic woman married a healthy husband, and, having had by him several healthy children, was subsequently impregnated by the man who originally communicated the disease to her, to whom she bore a syphilitic child, who died of the disease. Professor Fournier summed up this part of the subject by giving statistics of the mortality from the three sources of inheritance. Thus in paternal heredity the mortality when the disease manifested itself was 28 per cent.; in maternal, 60 per cent.; in mixed heredity, 68·5 per cent. Entering now on the consideration of the conditions which modify the influence of heredity, he first discussed that of *time*. He showed that this alone, without any treatment, lessened, and at times even annulled, the power of syphilis to transmit itself from parent to offspring, and in support of this statement he quoted some remarkable figures. He further proved that the three years following the first manifestation of the disease were by far the most destructive. Thus of 176 deaths of infants, 139, or about four-fifths of the whole, resulted from syphilis which was not over three years old in the parent, and that after that a marked diminution in the mortality set rapidly in. These considerations, continued the distinguished speaker, naturally suggested the question—Has syphilis its limit of age where its hereditary influence ceases to be felt, and, if so, what is it? Here, added he, a categorical answer was impossible. The most that can be said was that, after a certain number of years, the hereditary influence was certainly greatly reduced, and was, if not altogether extinguished, at any rate extremely attenuated. On the other hand, M. Fournier was able to say, from a multitude of observations, many of which he quoted, that the hereditary influence might be manifested as late as sixteen years from the date of first infection. Some observers had even gone further, and spoken of the taint being apparent as far as the second generation. Having thus discussed the influence of time, he next passed to that exercised by *treatment*. Here M. Fournier would at once say that the beneficial effects of well-directed treatment were nothing short of marvellous. Nor was this effect manifested as the exception, but as the rule. And further, this remedial action obtained equally well whether the affection had its origin with the father or mother, or both. Indeed, the unerring effect of treatment was so marked and immediate that it was well to be on our guard lest we mistook a mere provisional amelioration for a permanent cure. And this provisional improvement was itself a striking illustration of the benefit of treatment. Here the Professor cited the case reported by Turkmann, where a syphilitic mother gave birth to seven syphilitic children in successive pregnancies, neglecting all treatment. During her eighth and ninth pregnancies she was treated, and the result was the birth of healthy infants. Becoming pregnant for the tenth time, and believing herself cured, she omitted treatment, and the result was a syphilitic child. Finally, in the course of her eleventh pregnancy, she again had recourse to treatment, with the same happy effect as in her eighth and ninth confinements. He then cited the results of (1) no treatment, (2) short treatment, (3) average-time treatment, and (4) prolonged treatment. Taking paternal heredity alone, which he had shown to be least destructive to the child, no treatment was followed by a mortality of 59 per cent.; short treatment (meaning by this where it did not extend beyond a few months) gave a mortality of 36 per cent.; average treatment (by which he meant treatment continued over a year) had a mortality of 21 per cent.; whereas by prolonged treatment it was reduced to 3 per cent. In the case of maternal heredity the figures were still more significant. He had under his care during the last two years thirteen women suffering from undoubted tertiary syphilis, but who, being ignorant of the nature of their malady, had had no treatment whatever. Now, following up these thirteen cases, he ascertained that these patients had together become the mothers of fifty-nine children. Of these fifty-nine, only ten were now living; forty-nine were either born dead or died shortly after birth—that is to say, a mortality of 83 per cent. Having thus shown the parallel and powerful effects of *time* and *treatment* when considered separately on hereditary syphilis, he said it was natural to suppose that these two factors in the cure would, when combined, continue to act in the same direction, but in a more certain and lasting manner, and this supposition was, in fact, well borne out by practice. These two elements in the cure, when thoroughly combined, completely changed the aspect of the otherwise despairing outlook, and reduced the risks to almost nothing. Since he had begun the study of the relations between syphilis and marriage, which had now occupied his closest attention for many years, many hundreds of his patients whose cases he knew *au fond* had married with his entire approval, and had had children whom he had the satisfaction to say were free from the smallest suspicion of heredity. Now what he termed his programme of admissibility to marriage rested chiefly on these two bases—viz., purification by *time* and purification by *treatment*. And the chronological minimum of this double method of elimination he would place at not less than three or four years. Under this time he did not believe it was safe to allow a syphilitic man to marry; while, after devoting this time to active treatment, he had no hesitation in asserting that he could enter the marriage state without dreading a shadow of danger either in his capacity as husband or father.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

A New Remedy.

WHILE working in the chemical laboratory of the Society of Physicists in Frankfort-on-the-Main, Herr H. Baum, chemist, recently discovered a substance which is likely to compete with salicylic acid as a remedy and antiseptic. This new substance, dithio-salicylic acid, consists, as it were, of two molecules of salicylic acid concatenated into one molecule by two atoms of sulphur. The well-known bacteriologist, Professor Hueppe of Wiesbaden, has ascertained that a 20 per cent. solution of sodium-dithio-salicylate kills anthrax spores in forty-five minutes, whereas sodium-salicylate under the same conditions has no perceptible effect. Its effect on cholera and typhus bacteria, on the bacterium of green pus, and on the staphylococcus aureus, is much stronger than that of sodium-salicylate. Sodium-dithio-salicylate II. (there is a similar substance called sodium-dithio-salicylate I.) has been tried in many cases of acute rheumatic fever in Dr. Knoblauch's wards in the city hospital of Frankfort, and Dr. Lindenborn reported on these experiments in No. 25 of the *Berlin Clinical Weekly*. In the slighter cases a dose of 0·2 gramme was given every morning and evening; in the severer ones the same dose every morning, and two, three, or four times an hour every evening. In slight cases pain, fever, and swellings disappear after two days; in severer ones, after six days at most. As compared with sodium-salicylate, sodium-dithio-salicylate possesses the following advantages: stronger effect and consequent adequacy of smaller doses, no bad effects on stomach, heart, and vessels, no collapse, no humming in the ears. A Frankfort physician had given a patient, who was suffering from acute rheumatic fever, 200 grammes of sodium-salicylate without any essential alleviation. He then tried the new remedy, giving the patient four doses of 0·2 gramme daily, which cured him in five days.

A Mineral Spring near Haarlem.

A very copious mineral spring was discovered some time ago near Haarlem. The water has been examined by the professor of chemistry in the University of Amsterdam, who declares that it contains so large a quantity of iron that it is surpassed in this respect only by the Pouchon spring at Spa. He found also a considerable quantity of common salt, earth-alkalies, and titanic acid in the water. The temperature is 11 degrees Celsius, and the spring yields 66 cubic metres of water in twenty-four hours. The water is clear, and remains so when poured into bottles. A committee has been formed in Haarlem, which has leased the spring for ninety-nine years. Plans for the erection of a kurhaus in the Friedrich's Park close to the town, and for conducting the water to it, have already been drawn up, and are to be carried out as soon as the committee has raised the necessary funds.

The Veterinary School in Stuttgart.

The students of the Veterinary School in Stuttgart have unanimously resolved not to attend the school next winter, because the hope that it would be raised to the rank of an academy (Hochschule) on the occasion of the recent celebration of the twenty-fifth anniversary of the King of Würtemberg's accession has not been fulfilled.

Poisonous Fungi.

The State authorities at Breslau have issued a warning against the eating of poisonous fungi, adding that all the popular methods of recognising the poisonous character of boiled fungi are deceptive and that no cookery can render them harmless.

New Hospitals for Berlin.

The operations preliminary to the building of a second lunatic asylum for Berlin were begun on the 29th ult. at Lichtenberg, near Berlin. It will accommodate 1000 patients. The building of a hospital of similar dimensions for epileptic patients at Biesdorf, also for the city of Berlin, is to be commenced in the autumn.

The New Museum for Natural Science in Berlin.

The entrance to the new Museum for Natural Science in the Invaliden Strasse is surmounted by statues of the geologist Leopold von Buch and the biologist Johannes Müller. The heads of Alexander von Humboldt, the mineralogist Weiss, and the zoologist Ehrenberg are sculptured above them in the wall. All these scientists except Buch taught in the University of Berlin. Buch lived in Berlin from 1806 till his death.

A Botanical Garden in the Cameroons.

Baron von Loden, governor of the Cameroons, intends to lay out a botanical garden at Victoria in that country, for the cultivation of plants useful in medicine and industry. The Berlin Botanical Garden has sent him a very large collection of such plants gratis. The site selected is not far from the base of the lofty Cameroon Mountains, and consists of heavy loam on a basis of volcanic rock. The above-mentioned gift of the Berlin Botanical Garden is a token of gratitude for some rare and valuable plants which it received from the Cameroons last summer, and which are thriving well here.

A Wonderful Cure.

The *National Zeitung* of Berlin relates the following remarkable story. The wife of a retired official of high rank in Havannah fell dangerously ill some time ago, and was despaired of by her physicians. She begged her husband to put her on board a ship bound for Spain that she might see her native land once more and be buried in its soil. Her husband fulfilled her wish, and she sailed next day for Santander. A coffin and all that was necessary for embalmment were put on board the ship, for the doctors said she could not live more than two or three days. But the voyage worked wonders. The lady recovered from day to day, and when the ship reached Santander, after a sixteen days' passage, she landed in good health and spirits.

The German Admiralty has given 4000 marks (nearly £200) towards erecting a second German hospital in Zanzibar.

Berlin, Aug. 6th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Meeting of the German and Austrian Anthropological Society.

THE first joint meeting of the Austrian and German Anthropological Society was recently held in the hall of the Vienna Society of Engineers, there being nearly 300 German and Austrian anthropologists present. The Vienna University was represented by several professors, among them being Zuckerkandl and Bruecke, but a great many German celebrities attended, including Professors Virchow, Waldeyer, Drs. Voss, Troeltsch, Bartels (Berlin), Professors Ranke and Rüdinger (Munich), Dr. Fraas (Stuttgart), and Professor Schaafhausen (Bonn). Two lady anthropologists were also present, one of them holding the post of curator of the Kiel Museum. The opening address was read by Baron von Andrian-Werburg, the president of the Austrian Anthropological Society. The guests were afterwards welcomed by a member of the Town Council and by the Austrian Minister of Public Instruction (Dr. von Gautsch), who alluded in his speech to the importance attributed to anthropological science by the Austrian Government. Professor Virchow gave an introductory address, which was listened to with great attention, and very frequently interrupted by loud applause. He stated that the idea of forming a German Anthropological Society was first conceived at the Innsbruck meeting of the German naturalists twenty years ago, when Professor Carl Vogt's lecture had given rise to a sharp controversy between anthropologists. Professor Virchow devoted a portion of his lecture to the question of nationality from an anthropological point of view, and he came to the conclusion that as there were so many differences, especially with regard to the formation of the skull among members of the same nationality, it was up to the present impossible to state the precise relationships existing between the different central European nationalities. He pointed out that Austria, on account of the many old nationalities living there, was one of the best countries for studying this difficult question. After a short allusion to the death of the Austrian Crown-Prince, who took such great interest in anthropological work, Professor Virchow claimed that human culture and progress were due not to the great mass of people, but to single individuals, who by their personal qualities, skill, and inventiveness helped on the progress of the whole race.

Digitized by Google

He next dwelt on the various views held by anthropologists regarding the bronze age, and showed the errors made by the old school of anthropologists. The Darwinian theory of the descent of man was also discussed and criticised. Professor Virchow maintained that the links proving the descent of man from lower animals had not yet been found, and that a real pro-anthropos had not yet been discovered. We cannot, he said, determine even the descent of single races familiar to us for many hundred years; all human races, as we know, are man-like, and not ape-like. From the examination of skulls and from other craniological studies, it may be concluded that no remarkable change of human types has taken place during the last 5000 years. In closing his very interesting lecture, Virchow pointed out that the progress of anthropology depended not upon forming hypotheses, but in following the paths of exact scientific research. To-day, he said, we know what we know. Rich material, however, had been stored by anthropologists in the course of the last twenty years, so that it would be possible in the next twenty years to clear up the relationship existing between European nationalities.

In the afternoon the rich anthropological collections of the new Imperial Natural History Museum, to be opened by the Emperor on Aug. 10th, were visited, while in the evening the members of the Congress were entertained by the municipality in the Town Hall.

Vienna, Aug. 7th.

Obituary.

JOHN SISSON STEELE, M.R.C.S., L.S.A.

THE friends of the late John Sisson Steele will read the announcement of his death with sincere regret. He was the son of Thomas Steele, who was a medical practitioner in Reigate for nearly fifty years, and from whom he received his early medical training. He afterwards studied at Guy's Hospital and Webb-street, and in the year 1830 received the L.S.A., and afterwards the M.R.C.S. He was born at Reigate in the year 1809, and died July 18th, 1889, in his eightieth year, after nearly fifty years in busy general practice. No man could have been more universally beloved by his patients, and in truth by all who had the advantage of his acquaintance, for he was a man who read much and thought profoundly. As an artist he had abilities of a high order, and doubtless would have made a reputation had he given art his undivided attention. He numbered many artists amongst his friends. Sir Edward Landseer was one from whose hands he had received many acts of kindness. Ten years ago failing health forced him to retire from active work. Valvular disease of the heart, coupled with advanced years, rendered him unable to combat the hot weather, and the life of a man who did not know how to do an unkind action slowly and quietly ebbed out.

Medical News.

UNIVERSITY OF LONDON: INTERMEDIATE EXAMINATION IN MEDICINE.—The following candidates passed the examination for Honours in July, 1889:—

Anatomy.

First Class.—Wm. M. Stevens (Exhibition and Gold Medal), University College.

Second Class.—Alfred Theodore Rake, Guy's Hospital; Charles Henry Preston, Owens College and Manchester Royal Infirmary.

Third Class.—William Lloyd Andriezen, University College; William Barnett Warrington, Owens College; Edward Chichester, London Hospital; Thomas Holmes, Guy's Hospital.

Physiology and Histology.

First Class.—Wm. M. Stevens (Exhibition and Gold Medal), University College; Harold M. Richards (Gold Medal), University College.

Second Class.—William Lloyd Andriezen, University College.

Third Class.—Alfred Theodore Rake, Guy's Hospital, and James Edwd Ramsay, University College (equal); Edwd. Thos. Ernest Hamilton, Guy's Hospital, and George Lancelot Rolleston, St. Bartholomew's Hospital and Cambridge University (equal); Emily Elizabeth Wood London School of Medicine for Women.

Organic Chemistry.

First Class.—William Lloyd Andriezen (Exhibition and Gold Medal), University College; *George Seaton Buchanan, B.Sc., St. Bartholomew's Hospital; Edward Eldridge Blomfield, London Hospital.

Materia Medica and Pharmaceutical Chemistry.

First Class.—William M. Stevens (Exhibition and Gold Medal), University College; *Thomas Holmes, Guy's Hospital; William Lloyd Andriezen, University College.

Second Class.—John C. Mackmurdo Given, Liverpool Royal Infirmary.

Third Class.—Arthur Mantell Daldy, Guy's Hospital; James Edward Ramsay and Harold Meredith Richards, University College.

The following candidates passed the entire examination:—

First Division.—Louisa B. Aldrich-Blake, London School of Medicine for Women; Hugh Wells Armstead, St. Bartholomew's Hospital; Chesman Barker, Sheffield Medical Institution; Vivian Boase Bennett, University College, Liverpool; Arthur Seal Blackwell, St. Bartholomew's Hospital; Claude Churchill Chidell, Univ. College; John Gray Clegg, Owens College; Richard Clegg, Owens College and Manchester Royal Infirmary; Charles Coles and Howard Owen Davies, St. Bartholomew's Hospital; Thos. Benj. Philip Davies, Guy's Hospital; Chas. Arthur Dixon, the Yorkshire College; Chas. Caldwell Elliott, Guy's Hospital; John Herbert Fisher, St. Thos.'s Hospital; Henry Wilkes Gibson, Middlesex Hospital; John Harvey, University College, Liverpool; Jessie Flewitt Hatch, London School of Medicine for Women; Percy Lord, Guy's Hospital; Wm. Percy Montgomery, Owens College; Edward Albert Nathan, St. Mary's Hospital; William Prior Purvis, St. Thomas's Hospital; Herbert Barnwell Rowbotham, Queen's College, Birmingham; Wm. Edward Sargant, St. Bartholomew's Hospital; Alfred William Sheen, Guy's Hospital; Gerald Allpress Simmons, St. Mary's Hospital; Hugh Roubiliac Smith, University College; Wm. Robert Smith, King's College; Caroline Sturge, London School of Medicine for Women; John Odery Symes, St. Mary's Hospital; Tom Robinson Taylor, Guy's Hospital; Wm. Longworth Wainwright and Cuthbert Sidney Wallace, St. Thomas's Hospital; George Alex. Watson, University College; Arthur Nesham Weir, B.Sc., and Charles Edwin Wheeler, St. Bartholomew's Hospital; Arthur Whitfield, King's College; Samuel Williams, University College; and Charles Jerome Woollett, Charing-cross Hospital.

Second Division.—Tom William Beazeley, Queen's Coll., Birmingham; Charles Bernard Braithwaite, Guy's Hospital; Stanley Mewburn Brown, Owens College; Frank P. S. Cresswell, B.Sc., Guy's Hospital; Howard Edward Girdlestone, St. Thos.'s Hospital; Edgar Huntley, Thomas David Lister, and James Hannay Muncaster, Guy's Hosp.; Alonzo George Rider, University College; Mary Louisa Sprigg, London School of Medicine for Women; Geo. Robt. Fabris Stilwell, St. Thomas's Hospital; Edward Gaved Stocker, St. Bartholomew's Hospital; Wilfrid Watkins-Pitchford, St. Thomas's Hospital; Harry Bacon Wilkinson, Guy's Hospital; Alfred Field Henry Wray, St. Bartholomew's Hospital; Sydney F. Wright, St. Thomas's Hospital.

Excluding Physiology.

First Division.—Edward Bulwer Allan, University College; William Tillinghast Atwool, St. Mary's Hospital; James Benzeville Byles, University College; Rowland N. U. Pickering, St. Barthol. Hosp.

Second Division.—Harry Finley, University College; Frank Drew Harris, St. Mary's Hospital; Alfred Hugh Minton, King's College; George Dines Parker, St. Bartholomew's Hospital; Reginald Mander Smyth, St. Mary's Hospital; James Hugh Sproat, Queen's College, Birmingham; Henry Eugene Tracey, St. Bartholomew's Hospital; Arthur Longley Whitehead, Yorkshire College.

Physiology only.

Second Division.—John Jas. Brown, Guy's Hospital; Joseph Richard Buckley, Owens College; Rupert James, University College; Geoffrey Colley March, Owens College; Elizabeth Margaret Pace, London School of Medicine for Women; Charles Barré Phipps Spencer, Guy's Hospital; Mildred E. K. Staley, London School of Medicine for Women; Frederick Wallace Wilson, Guy's Hospital; John Gratton Wilson, London Hospital.

* Obtained the number of marks qualifying for the Exhibition and Gold Medal.

UNIVERSITY OF EDINBURGH.—In our list of candidates recommended to receive the degrees of Bachelor of Medicine and Master in Surgery from the University of Edinburgh, published last week, the name William A. Bryant was inadvertently omitted.

BEQUEST. — Mercer's Hospital, Dublin, has received £177 15*s.* 9*d.* under the will of the late Mrs. Clouston.

JERVIS-STREET HOSPITAL, DUBLIN. — At the termination of the session the following prizes were awarded:—Senior Grade: Daniel Shanahan, gold medal. Junior Grade: Francis T. Greeves, gold medal.

ROSS MEMORIAL HOSPITAL, DINGWALL. — The Marchioness of Tweeddale formally opened on Aug. 6th a new wing to this hospital. This addition provides accommodation for six beds, two nurses' rooms, and other conveniences.

BITTEN BY A HYDROPHOBIA PATIENT. — The Bucharest correspondent of a news agency sends particulars of a painful occurrence which has taken place at Kustendjie, where a soldier was under treatment in the military hospital for hydrophobia. The patient, it is stated, bit through the hand of the surgeon attending him so severely and held on with so much force that the soldiers present had the utmost difficulty in freeing the surgeon, who has gone to Bucharest to be treated at the Institute for Bacteriology. The wound is severe, and the case is being watched with interest by the medical world.

SWEATING IN THE NAIL TRADE.—On Wednesday, at Dudley, a chainmaker was fined £23 for sweating persons in his shops.

SOME apprehension is being caused in the West-end by the occurrence of cases of enteric fever in that quarter of London. Complaints are made of noxious odours arising probably from defective drains. It is well known that the drainage of even better-class houses in the fashionable part of the metropolis is not above suspicion.

LITERARY INTELLIGENCE. — Messrs. Funk and Wagnalls, of 44, Fleet-street, London, will publish next week a medical book entitled "Emergency Notes, or what to do in Accidents and Sudden Illness till the Doctor comes," price 2*s.*, by Glentworth R. Butler, A.M., M.D., Brooklyn, N.Y.

RABIES.—According to the *London Gazette*, the number of dogs in England reported during the week ending the 3rd inst. as afflicted with rabies was 15, against 7 reported in the previous week. Of these, 14 were killed and 1 died. Of the 15 diseased animals, 3 belonged to the metropolis, 2 to Kent, 2 to Surrey, and 5 to York, West Riding.

HYDROPHOBIA.—An extraordinary case of hydrophobia is stated to have occurred near Sheffield. It appears that an iron-moulder named Parkins died after several days' acute suffering, although there was no evidence of his ever having been bitten by either a dog or a cat. The doctor's opinion is that the malady was caused by the deceased having been licked by a dog on the face, at a spot where he had cut himself by shaving.

MERTHYR GENERAL HOSPITAL.—At a meeting of the governors of this institution held last week, the chairman stated that from Oct. 22nd last, when the hospital was opened, to June 30th, 99 patients had been admitted, of whom 5 had died. There were 11 patients at the present time. Most of the cases had been accidents. The report and the accounts, which showed a satisfactory balance, were passed.

FEVER HOSPITAL ACCOMMODATION IN BIRMINGHAM.—Another ward has been added, as a precautionary measure, to the Infectious Hospital in Birmingham, in view of the continuance of scarlet fever in that town. A boy having contracted the disease from sleeping among the rags and refuse collected in a marine store in Allison-street, the health inspector, acting for the Health Department, purchased the entire contents of the shop and had them destroyed.

THE DWELLINGS OF THE POOR.—The usual monthly meeting of the Mansion House Council on the Dwellings of the Poor, of which the Lord Mayor is president, was held on Tuesday in the Long Parlour. The report presented by Mr. John Hamer (hon. secretary) showed that action had been taken with respect to insanitary conditions in Finsbury, Bethnal-green, Newington, St. George's-in-the-East, and Shoreditch. It was reported that active steps had been taken with regard to the retention of open spaces in Bethnal-green.

TWIN CENTENARIANS.—The following statement has appeared somewhat extensively in the public press:—On the 12th inst. at Coosat, a village near Athlone, Margaret Mulochill, 100 years of age, gave evidence at a coroner's inquest relative to the death of Honora, her twin sister. The old women lived together, and on Saturday, when Margaret went to the market she left Honora at home in good health. On returning she found her lying dead on the sofa. Death had resulted from failure of the heart's action.

SUPERANNUATION.—At the fortnightly meeting of the Hoxne Board of Guardians, held at Stradbroke last week, the official minute of the previous board meeting in reference to the superannuation vote to Mr. Read, medical officer of health for the Stradbroke district, was made public. From this it appeared that a motion to allow Mr. Read a superannuation allowance of £40 per annum was lost by 14 votes against 10, as was also, by 14 against 11, an amendment that no allowance whatever be made. A proposal was then carried by 16 votes to 1 that a donation of £145 be given to Mr. Read on his retirement from office.

BRITISH DENTAL ASSOCIATION.—The annual meeting of this Association will be held in Brighton on the 22nd, 23rd, and 24th inst. The retiring president is Mr. Daniel Corbett, and the president-elect Mr. S. Lee Rymer. At the first day's meeting Mr. Corbett will deliver his valedictory, and Mr. Rymer his inaugural, address, and papers will be read on a variety of subjects connected with dental practice. On the Friday the reading and discussion of papers will be resumed, and in the evening the annual dinner of the members will take place in the Pavilion. Saturday will be mainly devoted to demonstrations.

GLASGOW UNIVERSITY STUDENTS' UNION BAZAAR. An influential committee has just been formed in London to promote the interests of this movement. It comprises the names of the Duke of Argyll, the Earl of Stair, Sir Francis Sandford, Professor Bryce, M.P., Dr. Cameron, M.P., Dr. J. A. Campbell, M.P., the Rev. P. H. Aitken, the Rev. H. Sinclair Paterson, Drs. D. W. Finlay and Norman Kerr, Messrs. P. E. Dove, F. W. Clark, T. C. Hedderwick, Joseph Bain, J. J. Stevenson, and J. Hardie; with Mr. J. R. McIlraith, Barrister-at-law, 2, Essex-court, Temple, E.C., as secretary and treasurer, to whom all subscriptions should be sent.

PROPOSED EXTENSION OF THE CARDIFF INFIRMARY.—At a recent meeting of the general committee of the board of governors, a report was considered from the buildings committee bearing upon the extension of the infirmary. This report, which was unanimously adopted, recommended the erection on the south side of a new ward generally similar to the existing male ward, in which provision is to be made for sixty additional beds, including space for the ophthalmic ward. The cost of the extension will be about £8000, towards which a sum of about £1000 is in hand. The enlargement of the infirmary has long been needed, and it is now to be carried out on a scale commensurate with the requirements of the institution.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.—The fifty-seventh report of this institution is, on the whole, satisfactory. The total number of in-patients was less than last year, a decrease attributed to the severity of the cases treated. The average time occupied by each patient was thirty-seven days, against thirty the previous year. The daily number of patients in the hospital averaged eighty-two, compared with seventy-seven last year. The balance-sheet showed a deficiency of £662 8*s.* 3*d.* in the ordinary annual income, but this deficit had been made up by deducting the amount from legacies received—viz., £1042 18*s.* 4*d.*, instead of placing the whole sum to hospital account.

VICTORIA JUBILEE INFIRMARY, NORTH SHIELDS. This institution was formally opened by Earl Percy last week, in the presence of a large and representative gathering, including many members of the local medical profession. The financial statement showed that while the total cost of the building, exclusive of furniture, was £3264 15*s.* 3*d.*, donations &c. amounted to £3112 1*s.* 2*d.*, leaving the small balance of £152 14*s.* 1*d.* to be raised to cover the cost of the building. This result his lordship explained had been almost entirely achieved by the efforts of the class which would be mostly benefited by the establishment of this institution. The proceedings wound up with a luncheon at Tynemouth.

PRESENTATIONS.—A valuable and very beautiful silver inkstand has just been presented to Mr. Jackson by his colleagues in the Sheffield School of Medicine, on the occasion of his retirement, after many years of unremitting and successful work, from the hon. secretaryship of the school. The inkstand presents in front an excellent engraving of the new buildings of the Medical School which were opened last year by Sir Andrew Clark, and to the successful completion of which the exertions of Mr. Jackson have largely contributed. With the inkstand was an illuminated address, signed by the president, treasurer, and teachers of the school, to the following effect: "Presentation to Arthur Jackson, Esq., surgeon to the General Infirmary, and lecturer on Surgery in the School of Medicine, Sheffield. August 9th, 1889. — Dear Mr. Jackson: In asking your acceptance of the accompanying silver inkstand, we, your colleagues, wish to express our united and cordial esteem for you personally, and our grateful sense of your most valuable services to the school as its honorary

Digitized by Google

secretary during the last twenty-one years."——On the 2nd inst. the members of the staff of the Joint Counties Lunatic Asylum, Carmarthen, presented a handsome gold watch to Mr. John Powell, L.R.C.P., L.R.C.S. Edin., the senior assistant medical officer of the asylum, on his resigning that post.

ACCOMMODATION FOR LUNATICS IN CHESHIRE.—Cheshire has just now a difficulty in providing accommodation for its lunatics. The Parkside and Upton Asylum, belonging to the county of Cheshire, being full, the Cheshire County Council has given the Corporation of Chester six months' notice in which to remove all their pauper lunatics, numbering 109. It is said that something like £40,000 will have to be spent in providing an asylum, or else the lunatics will have to be sent to distant places. The question is to be further discussed at a future meeting of the Town Council.

PROVINCIAL HOSPITAL SUNDAY COLLECTIONS.—The Hospital Sunday collection this year, by the local friendly societies of Netherton, in aid of the Dudley Guest Hospital, amounted to £33. The recent Oxford friendly and benefit societies hospital Sunday collection, on behalf of the local hospitals, realised (net) £83 9*s*. The Liverpool Hospital Sunday collections have produced this year £6803, being an increase of about £346 on 1888. The annual friendly societies hospital parade, at Abingdon, on the 28th ult., for the benefit of the Cottage Hospital, amounted to £34 4*s*.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—The annual meeting of this Association will be held in Newcastle-upon-Tyne from the 11th to the 19th prox. The programme, which can be obtained from the Tyne Printing Works Company, 26, Side, Newcastle, contains, in addition to full particulars of the meeting, portraits and memoirs of the presidents and lecturers—viz., Professor W. H. Flower, F.R.C.S., &c., Captain Abney, Sir Lowthian Bell, Bart., Professor James Geikie, Professor Burdon-Sanderson, M.D., Sir Francis de Winton, Professor Edgeworth, William Anderson, C.E., Sir Wm. Turner, M.B., Professor Roberts-Austen, Benjamin Baker, C.E., and Walter Gardiner, M.A.

RETIREMENTS OF MEDICAL OFFICERS OF HEALTH.—There were forty-six applications for the post of medical officer to the borough of Nottingham, about to become vacant by the resignation of Dr. Whitelegge, who is proceeding to Yorkshire. Of the forty-six applicants, six were selected, from among whom the final appointment will be made. The salary is £500 a year.—At a meeting of the Hoxne Board of Guardians at Stradbroke last week, a letter was read from Dr. W. H. Anderson, resigning his appointment of district medical officer of the Fressingfield, Laxfield, and Mendham districts, also of public vaccinator for the same districts, and of medical officer of health for the whole union.

ROYAL BOTANIC SOCIETY OF LONDON.—The fiftieth anniversary meeting of this Society was held in the gardens last week. It appeared from the report that the scientific work of the Society had shown great improvement, 744 students having received free admissions of from one to three months each, and 42,000 specimens of plants and flowers having been cut for study and examination by the various colleges, hospitals, and medical schools in London. The collections of medicinal, economic, and interesting plants had been largely increased. The Council hoped to continue next year the valuable lectures by well-known professors in the chief departments of economic and biological botany.

QUARANTINE.—The *London Gazette* of the 9th inst. publishes a telegram from the British representative at Constantinople announcing the imposition of ten days' quarantine on all arrivals from Bussorah in consequence of cholera. Quarantine has also been established at all Egyptian ports against arrivals from Massowah. The Governor of Malta has directed that vessels arriving through the Suez Canal shall be subjected to medical visit, and that no linen, wearing apparel, or other susceptible articles shall be allowed to be landed before they are disinfected. Quarantine drawbacks exist slightly at Odessa and Kertch; there are no pilots at Sevastopol, and the roadstead at Taganrog is an obstacle; whilst the inconsiderable size of the port of Batoum is frankly alluded to. The Russian authorities, however, have shown a desire to meet the proposals suggested, as far as local circumstances will permit, and as regards certain complaints by the owners and masters of British vessels, it appears that misrepresentations have been made.

CRUELTY TO CHILDREN IN RUSSIA.—The *Archiv für Eisenbahnwesen* says: "The Russian Ministry of the Interior has just issued an ordinance to all railway officials prohibiting the further 'packing of small children (literally 'sucklings') in baskets, to the number of eight in a basket (!), and forwarding them to the foundling-houses in the great towns as hand luggage.' This abuse, says the Ministry in the Circular, is no longer to be tolerated, since it involves a serious injury to the health of the children, and is also an attempt to evade the regulations for the carriage of passengers by rail. In Russia 'infants must be paid for.'"

MEDICAL NOTES IN PARLIAMENT.

Prevention of Cruelty to and Protection of Children Bill.

IN the House of Lords, on Thursday, the 8th inst., an amendment by Lord Milltown, allowing the sale of newspapers &c. in the streets in winter time by children under fourteen years of age up to 10 P.M. instead of 8 P.M., as proposed by the Bill, was carried by 23 to 13. Words were inserted placing circuses and travelling shows on the same footing as theatres as regarded the employment of children. On the following day (Friday, the 9th), an amendment was agreed to enacting that that portion of the subsection relating to the employment of children in places of amusement should not come into force until Nov. 1st, 1889. The Bill was then agreed to.

In the House of Commons on Wednesday, the 14th inst., the Lords' amendments were considered.—Mr. Fowler said that, in the absence of his hon. friend the member for Sheffield (Mr. Mundella) he had to ask the House to agree to the Lords' amendments. These were, with three exceptions, amendments which dealt mainly with procedure, and, as they had been mostly introduced at the instance of Lord Herschell, and, as all of them had been adopted under the supervision of Lord Herschell, and with the approval of the Lord Chancellor, he thought the House might rest satisfied to accept them. There were, however, three amendments of substance. As the Bill left this House the hours after which children were not to be employed in the streets were fixed at 10 o'clock at night in summer and 8 o'clock in winter. The House of Lords had thought fit to fix 10 o'clock as the hour all the year round. He regretted this alteration, but it must be borne in mind that power was reserved to the local authority to further extend or restrict the hours. The next amendment of substance was with regard to the position of a wife in regard to giving evidence against her husband. As the Bill left the House it was provided that the wife should be a competent and compellable witness. The House of Lords had altered that by providing that the wife should attend the court and be competent as a witness, but on her refusal to give evidence should not be compellable. The third amendment was the most important of all, and dealt with the employment of children under ten years of age in theatres. In this House it was carried by large majorities that such employment should without exception be prohibited. The alteration effected in the House of Lords was that as to children under seven years the clause remained unaltered, and the prohibition absolute; but as to children above that age power was given to a petty sessional court to grant licences for such employment. Now he regretted that amendment, but they had to deal with this matter as practical men, and looking to the state of public business and the fact that this amendment had the support of Her Majesty's Government in the other House, and that they were not likely to assent to its abandonment, if this amendment were not agreed to by the House of Commons the result would be a wrangle and the inevitable loss of the measure. Under these circumstances, having regard to the fact that this was a vexed question upon which many people just as philanthropic as themselves took different views, and that a fair compromise had been obtained, he hoped that the House would agree with the amendment, and thus permit the Bill, which would be a great boon to the children of this country, to become law without any further delay. The Lords' amendments were then agreed to *en bloc*.

Lunacy Acts Amendment Bill.

On Thursday, the 8th inst., the Commons' amendments to this Bill were considered and agreed to; and in the House of Commons, on Monday, the 12th, the Lords' amendments to the Commons' amendments were considered and for the most part agreed to.

Universities (Scotland) Bill.

The Marquis of Lothian explained that last year a Scotch University Bill was carefully considered and read a third time in that House, but the House of Commons had not time to deal with it. This year the Bill was introduced first in the House of Commons, and was practically the same Bill. After some discussion, the Bill, with slight amendments, passed through committee, and was read a third time and passed on Monday, the 12th inst.

Local Government (Scotland) Bill.

On Friday, the 9th inst., this Bill was read a third time, and, some verbal amendments having been agreed to, was passed after an ineffectual protest from Lord Denman.

Digitized by Google

Adulterated Lard.

In the House of Commons, on Thursday, the 8th inst., Sir Michael Hicks-Beach, in reply to Sir R. Paget, said the Government were not prepared to prohibit all adulterations of lard, as besides the great cost of testing all imports there was no evidence that the bulk of such lards was other than harmless, the ingredients of those compounds consisting in a great measure of cotton-seed oil. The Customs were prepared to assign a separate heading for "lardine" in the import accounts of next year.

Fever in the Spanish Pavilion, Gibraltar.

In answer to Sir W. Barttelot, Mr. Brodrick (Financial Secretary, War Office) said that there had been three cases of fever, of which two were enteric, in four adjoining rooms on the ground floor of the Spanish Pavilion during the last eleven months. The rooms of the lower floor had been closed, and steps had been taken for dealing at once with the sanitary defects of the Spanish Pavilion, if any remained, after the overhaul it recently underwent. There had been no case of fever since June.

Myopia in Elementary Schools.

In reply to Dr. Farquharson, Sir W. Hart Dyke said that, as the inspectors had no previously ascertained data upon which to form a comparative judgment as to the alleged increase of short sight in the children attending public elementary schools, a considerable time would necessarily elapse before they could be expected to give an opinion; but the matter had not been lost sight of, and he hoped it might be possible to secure some reliable information in connexion with it.

Overhead Wires.

In answer to Sir Geo. Campbell, Mr. Ritchie stated that obviously no legislation on this question could be proposed this session, and he could not make any statement as to what might be proposed in a future session.

Consolidation of the Lunacy Laws.

In reply to Mr. Salt, Mr. W. H. Smith stated that an amendment had been inserted into the Lunacy Amendment Bill postponing its operation until next May, with the express view of making it possible to pass a Bill consolidating the Lunacy Acts before that date. This Consolidation Bill would be laid on the table of the House of Lords this session.

The Health of Mr. Conybeare, M.P.

In reply to Mr. MacNeill and Mr. McArthur, Mr. Balfour stated that the medical officer of the prison, who was a most competent gentleman, had daily opportunities of seeing Mr. Conybeare. It was the medical officer's business to report to the Prisons Board if there was anything in the prison cells injurious to health; and further, he had ample power, without going to the Prisons Board, to take steps for preventing injury to the health of prisoners.

The Medical Act (1886) Amendment Bill.

The order for this Bill was discharged, and the Bill itself withdrawn.

Pollution of the River Lea.

On Friday, the 9th inst., in reply to Sir J. Colomb, Mr. Ritchie stated that he was still awaiting a reply from the West Ham Corporation with regard to the allegations made against that body by the Poplar District Board of Works. Meanwhile he had directed an engineering inspector to visit West Ham and report the result of his inquiries, and he expected to receive his report shortly.

A Court for Criminal Appeal.

Mr. F. Maclean gave notice that as early as possible next session he should call attention to the advisability of constituting a court of appeal in criminal cases, and move a resolution.

Exceptional Children in Primary Schools.

In answer to Dr. Farquharson, Sir W. Hart Dyke said his attention had been called to a draft report on the condition of "exceptional children in primary schools," prepared by Dr. Francis Warner as honorary secretary of a committee appointed by the Psychological Section of the British Medical Association to consider this subject. He had no doubt that the intrinsic importance of the medical questions with which it dealt would obtain for it a sufficient share of public notice, but he had neither the means nor the right to authorise the publication of the full text of the investigations or of anything connected with the inquiry, as requested by the hon. member.

Medical Superannuation.

On Monday, the 12th inst., Mr. A. J. Balfour, answering Mr. Pinkerton, said the grounds upon which a superannuation allowance may be granted by the guardians of a union to an officer appointed under the Medical Charities Acts are permanent infirmity of body or mind or old age. The Local Government Board have been advised, in reference to a case which came before them, that there was no legal obstacle to a retiring allowance being granted to a medical officer in respect of an office under the Medical Charities Acts, although he might continue to hold another and distinct appointment under the Poor Law Acts, but the circumstances which could ever give substantial justification for such a proceeding must obviously be very exceptional.

Alleged Typhus in Derry Gaol.

In reply to Mr. Sexton, Mr. A. J. Balfour stated that of the three Falcarragh prisoners recently released from Derry Gaol one had since died of typhus fever. (Mr. Sexton: He was delirious when let out.) He (Mr. Balfour) had not heard of the illness of the two other prisoners from typhus as described by the right hon. gentleman. He did not think that particular circumstances connected with Derry Gaol had any bearing on the case of Mr. Conybeare. (Mr. Sexton: It is a dangerous gaol.) Mr. Balfour proceeded to say that the fact of a person recently released from Derry Gaol having died of typhus supplied very adequate ground for making a most careful inspection of the gaol, and the necessary inquiries were now being made.—Mr. Sexton said they would have to discuss in Supply whether this Derry Gaol was not a death trap.—Mr. Balfour said it was not absolutely certain that the man did die of typhus. There seemed to be some doubt about it.

Public Health (Cholera Prevention) Bill.

Mr. W. H. Smith, in reply to Mr. E. Robertson, said that it was not in his power to give any assurance that no more departmental Bills such as this would be introduced this session. Emergencies might arise at any moment rendering it necessary to introduce measures of this character in the public interest.—Mr. Ritchie moved for leave to bring in the Bill, and it was read a first time.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BOOTH, W., L.R.C.P. & S.Ed., F.R.C.S.E., has been appointed Medical Officer to the Edinburgh Provident Dispensary.

BUXTON, H., L.R.C.P. & S. Edin., L.F.P.S. Glas., has been appointed House Surgeon to the Ripon Cottage Hospital and Dispensary.

EGAN, FRANCIS, L.K.Q.C.P. Irel., L.M., L.R.C.S. Irel., has been re-appointed Medical Officer of Health of Fulham.

EXLEY, JOHN, L.K.Q.C.P. & L.M. Irel., M.R.C.S., has been appointed Medical Officer of the New Wortley District, Bramley Union.

HILL, A. B., M.D. Giessen, L.R.C.P., L.M., L.R.C.S. Edin., has been reappointed Analyst of the Borough of Leamington.

KEILLER, WM., L.R.C.P. & S.E., has been reappointed Assistant Medical Officer to the Edinburgh Provident Dispensary.

MATHESON, A. A., M.D., F.R.C.P.E., has been reappointed Medical Officer to the Edinburgh Provident Dispensary.

MUIR, W. L., L.R.C.P., L.M. Edin., L.F.P.S. Glas., has been appointed Medical Officer to the Fourth District, City Parish of Glasgow.

MULLEN, JOHN W., L.K.Q.C.P.I., L.R.C.S.I., &c., has been appointed Medical Superintendent of the Wilton Fever Hospital in the County Borough of Salford, vice Dr. John Tatham, appointed Medical Officer of Health to the City of Manchester.

MURDOCH, W. H., M.D., M.S.Irel., has been appointed Assistant Medical Officer of the Workhouse Infirmary, Parish of Liverpool.

ORR, HUGH, L.R.C.P., L.R.C.S. Edin., has been reappointed Medical Officer and Public Vaccinator, Filey District, Scarborough Union.

ORR, R., M.D. Glas., L.R.C.S. Edin., has been appointed Vaccinator for the Parish, Glasgow.

PURSLOW, C. E., M.D. Lond., M.R.C.S., has been appointed Honorary Medical Officer to the Birmingham Lying-in Charity, vice A. F. Hawkins, F.R.C.S.E., resigned.

READ, HAROLD WM. KINGCOMBE, L.R.C.P., L.R.C.S., L.F.P. & S.Glas., has been appointed Medical Officer and Public Vaccinator to the Towcester Union and District, vice A. G. Evans, deceased.

ROBERTS, JOHN LLOYD, M.B., B.Sc., B.A. Lond., M.R.C.S., L.R.C.P., has been appointed Resident Medical Officer to the Eastern Counties Asylum for Idiots, Colchester, Essex, vice Herbert Evelyn Crook, M.B., B.S. Lond., F.R.C.S. Eng., L.R.C.P., resigned.

RUSSELL, JAMES, M.B. & C.M. Edin., has been appointed Medical Officer of the Workhouse Infirmary and the North Keighley District, Keighley Union.

SOPER, R. W., M.R.C.S., L.S.A., has been reappointed Medical Officer of Health, Dartmouth Borough, and Port Medical Officer.

STALKART, C. E. G., M.B., C.M., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer to the Edinburgh Provident Dispensary.

STEPHEN, JAMES, M.D., M.B., C.M. Aberd., has been reappointed Parochial Medical Officer, Peterhead, Aberdeenshire.

WHEATLEY, THOMAS DALEMAIN, M.D. Edin., M.R.C.S., L.A.C., has been appointed Chief Medical Officer to the French Co. of Venezuelan Railways.

WILLETT, G. G. D., M.R.C.S., L.S.A., has been reappointed Medical Officer of the Districts of Bitton and Marksbury, Keynsham Union.

WILSON, GEORGE, M.D. Edin., M.B., C.M., has been reappointed Medical Officer of Health, Mid-Warwick Sanitary District.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

BOROUGH OF LEEDS.—Medical Officer of Health. Salary £700 per annum, with disbursements.

CANCER HOSPITAL (FREE), Fulham.—Two Resident House Surgeons for six months. An honorarium at the rate of £50 per annum each, with board and residence.

CHILDREN'S HOSPITAL, Birmingham.—Resident Medical Officer and Assistant Resident Medical Officer. The salaries are £80 and £40 per annum respectively, with board, washing, and attendance in the hospital.

CITY ASYLUM, Birmingham.—Resident Clinical Assistant. Board, lodging, and washing provided, but no salary.

GENERAL HOSPITAL, Birmingham.—Resident Surgical Officer. Salary £130 per annum, with residence, board, and washing.

KINGSTON UNION (Offices: St. James'-road, Kingston-on-Thames).—District Medical Officer for the Parish of Teddington. Commencing salary £80 per annum, in addition to extra medical fees for operations, amputations, and to the payment for quinine, cod-liver oil, and linseed meal, at cost price.

NOTTINGHAM GENERAL HOSPITAL.—Resident Medical Officer for six months. No salary, but board, lodging, and washing in the hospital.

Digitized by Google

RURAL SANITARY DISTRICTS OF KENDAL, EAST WARD, AND WEST WARD UNIONS, AND THE URBAN SANITARY DISTRICTS OF KENDAL, AMBLESIDE, APPLEBY, BOWNESS, GRASMERE, AND WINDERMERE, all in the county of Westmoreland, in combination.—Medical Officer of Health. Salary at the rate of £375 per annum, to include travelling and other expenses and disbursements.

VICTORIA INFIRMARY, Glasgow.—Superintendent and Resident Medical Officer. Salary £125 per annum, with apartments and board.

WALLASEY DISPENSARY (Honorary Secretary, Elm Mount, Penkett-road, Liscard, Cheshire).—House Surgeon. Salary £110 per annum, with furnished apartments, coals, and gas.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—House Physician (who will also be required to act as Chloroformist, Pathologist, and Medical Registrar). Salary £100 per annum, with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

CHATTERJIE.—On Aug. 13th, at 173, Gloucester-road, Regent's-park, the wife of Surgeon-Major N. Chatterjie, Indian Medical Service, of a daughter.

EVERARD.—On Monday, July 1st, at Estcourt, Natal, the wife of Horace N. Everard, M.B., of a son, stillborn.

HENDERSON.—On Aug. 10th, at 66, Camp-road, Leeds, the wife of Robert Wilson Henderson, M.D., of a son.

MINNS.—On Aug. 2nd, at White Hart-street, Thetford, Norfolk, the wife of Allan Minns, L.R.C.P. Lond., &c., of a daughter.

SAUL.—On Aug. 11th, at Manor House, Selsey, Chichester, the wife of William Saul, M.D., of London, of a daughter.

TRAVERS.—On Aug. 7th, at Phillimore-gardens, W., the wife of Dr. Travers, of a son, stillborn.

MARRIAGES.

CALTHROP—HARTLEY.—On July 4th, at the Cathedral, Lahore, Punjab, Surgeon-Major Christopher William Calthrop, M.D., Indian Medical Service, to Alice Evett, second daughter of the late Charles James Hartley, Esq., of Edgbaston, Warwickshire, England.

COMPTON—SYMES.—On Aug. 7th, at the Parish Church, Allington, Bridport, Francis Charles Compton, L.R.C.P., M.R.C.S., of Bayard Lodge, Poole, Dorset, to Agnes, eldest daughter of the late William Legge Symes, of Magdalen House, West Allington, Bridport.

GREIG—LARKINS.—On Aug. 7th, at the Cathedral, Gibraltar, William Charles Greig, M.B., C.M.Edin., to Rosa Marion, youngest surviving daughter of Frederick Larkins, of Auckland, N.Z., and London.

HAMERTON—JONES.—On Aug. 7th, at St. John's Parish Church, Aberdare, George Albert Hamerton, M.D., to Mary Cook Jones, second daughter of J. O. Jones, Mining Engineer, Cwmdwr, Clydach, near Swansea.

MACGILLIVRAY—KENT.—On Aug. 7th, at Kesgrave Parish Church, Suffolk, Charles Watson Macgillivray, M.D., F.R.C.S. Edinburgh, to Frances Anne, eldest daughter of Francis Aldous Kent, Kesgrave Hall, Suffolk.

ROGERS-TILLSTONE—WILKINSON.—On Aug. 8th, at St. Patrick's, Brighton, Hermann Rogers-Tillstone, M.B., &c., third son of B. T. Rogers-Tillstone, of Moulse, Coomb Place, Sussex, Esq., to Amy Legge Wilkinson, youngest daughter of the late Thos. Wilkinson, Esq., of Stanford House, West Brighton.

SAVORY—ROW.—On Aug. 8th, at St. Stephen's, Tunbridge, William Harmsworth Savory, M.R.C.S. &c., of Ashford, Kent, eldest son of Charles T. Savory, M.D., of Canonbury, to Grace, youngest daughter of the Rev. John Row, of Tunbridge.

STYAN—NORBURY.—On Aug. 7th, at St. Pancras Church, Thomas Geo. Styan, M.A., M.D. Cantab., M.R.C.S., of Chapel-place, Ramsgate, eldest son of Thomas Styan, Esq., of Upper Bedford-place, Russell-square, London, to Alice Sophia, second daughter of John Norbury, Esq., of Gordon-square, London, and Springfield, Congleton, Cheshire.

WINSTANLEY—MOTT.—On Aug. 7th, at Haslemere Church, Robert Wyndham Winstanley, L.R.C.P., M.R.C.S., and L.S.A., eldest son of the late Octavius Winstanley, of Forest-hill, to Alice (Sissie) Mott, elder daughter of the late Angelo T. B. Mott, of Greyswood.

DEATHS.

BAIKIE.—On Aug 5th, at Melville-street, Edinburgh, Robert Baikie, of Tankerness, M.D., H.E.I.C.S., Vice-Lieutenant for the County of Orkney and Shetland, aged 89.

CHALMERS.—On June 24th, at Brisbane, Queensland, Charles Bonner Chalmers, late Deputy Inspector-General of Hospitals, H.E.I.C. Service, aged 70.

FORESTER.—On Aug. 12th, at Barnstaple, Henry Forester, M.D.Aberd., M.R.C.S., aged 61.

ROSS.—On Aug. 3rd, at Chaussée de Charleroi, Brussels, Charles G. H. Ross, Surgeon-Major, late of the Bombay Army, aged 63.

SMITH.—On Aug. 8th, at Sundown, St. Aubins, Jersey, Robert George Fothergill Smith, M.D.

SMITH.—On Aug. 3rd, at Bhamo, Upper Burmah, of intermittent fever, Surgeon-Major James Adolphus Smith, youngest son of the late Richard Smith, Surgeon, of Winchcombe, Gloucestershire, aged 41.

TERRELL.—On Aug. 14th, at his residence, Herbert Villa, Pembroke-road, Clifton, Frederick Terrell, M.R.C.S., L.S.A., aged 85.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE STUDENTS' NUMBER OF "THE LANCET" will be published on Saturday, September 7th. Those gentlemen holding official situations connected with medical institutions in the United Kingdom who have not yet forwarded the necessary information to our Office for publication in that number are earnestly requested to send it *without the delay of a single post.*

MALCOLM MORRIS INDEMNITY FUND.

THE following additional subscriptions to the above fund have been received:—

Amount previously acknowledged	£452	15	0	Dr. E. L. Birkett.. ..	£1	1	0
Dr. Bristowe	2	2	0	H. H. Clutton, Esq. ..	1	1	0

District Medical Officer.—If a patient has been attended continuously throughout the year on one order, that patient should be counted once; but if there have been two or three separate attendances, and a fresh order has been made for each, then each order should be counted as a fresh case.

A Subscriber.—We do not see the exact meaning of the questions. Will our correspondent rewrite them, and make his meaning a little clearer?

A. B. (Begelley).—Water containing in solution free carbonic acid as well as oxygen dissolves zinc to a very serious extent.

Mr. Jeaffreson (Newcastle-on-Tyne).—Yes, if of moderate length.

Dr. J. Mason (Blyth) is thanked.

THE LATE CHARLES SAMUEL WEBBER.

To the Editors of THE LANCET.

SIRS,—The case of my late esteemed friend, Mr. C. S. Webber, whose obituary appears in THE LANCET of to-day's date, well illustrates a remark made by Dr. Goodhart in your journal of July 6th, page 7, regarding "faulty habit." "The conscious direction of attention," writes Dr. Goodhart, "upon any pain, however slight, for a length of time will gradually make a trifle unbearable, and even apparently agonising; and there is many a sufferer whose sole ailment is thus generated, and whose successful treatment is to be compassed not with drugs....." For many years both my son and myself freely expressed our opinion both to the patient and his family that there was no organic mischief, and endeavoured, unsuccessfully I regret to say, to allow nature to act alone, assuring him that were he to resign himself unreservedly to proper care a cure was possible.—I am, Sirs, yours truly,

Boundary-rd., N.W., Aug. 10th, 1889. RICHD. NEALE, M.D.Lond.

AMENDMENT OF THE VACCINATION ACTS.—THE NUMBER OF INSERTIONS.

A CORRESPONDENT writes suggesting that in any amendment of the Vaccination Acts the form of certificate should be altered so as to show the number of insertions, and of those which have been successful. He states that merely to please parents some vaccinators vaccinate very imperfectly or in only one place, and that to such poor vaccination some of the discredit of the operation is due. We agree to a great extent with our correspondent. If one thing is more clear than another, it is that the protective power of vaccination is in proportion to the number of good vesicles produced. Our correspondent also urges more effective inspection of actual vaccinations and the appointment of inspectors from those who have distinguished themselves as good vaccinators—that is, "vaccinators who showed the largest percentage of good vaccine marks."

C. S. Watson.—The subjects referred to are dealt with at some length in Dr. Lauder Brunton's book on "Disorders of Digestion," more particularly in the paper upon "Poisons formed from Food, and their relation to Biliousness and Diarrhœa."

Dr. Fred. A. A. Smith.—Dr. Bull's work may be obtained of Mons. G. Masson, Boulevard St. Germain, Paris.

Dr. Bowie.—Yes, soon.

MEDICAL PRACTICE IN BRITISH COLUMBIA.

To the Editors of THE LANCET.

SIRS,—In your issue of June 29th is a letter *in re* English medical qualifications, signed "C. F. N.," in which the writer bewails his hard fate in having to pass an examination as well as pay a heavy fee before practising in this province. I am happy to say that the law does not apply to any man holding a British—i.e., English, Scotch, or Irish—qualification, and who has registered the same in Great Britain. All that such a one has to do is to produce his diploma and certificate of registration, make an affidavit before a justice of the peace that he is the person mentioned therein, and pay a registration fee of ten dollars. He may then practise wherever he likes in the province. I was under the same impression as your correspondent, and accordingly last April I paid a hundred dollars to the Council, and in due course passed the examination, receiving in return a certificate of registration. A month ago one of the Council was good enough to tell me that I could get back the hundred dollars by applying for them, as I was allowed in virtue of my diplomas (M.R.C.S.Eng., L.S.A.Lond.) to practise without examination. It appears that during the last session of the Local Parliament a number of Medical Acts were consolidated, and among them an Act of 1866 which was thought to have been repealed. Consequently, as the law stands at present, only men with British diplomas have the right of practising in this province without examination. All others, Canadians and Americans alike, have to pass that dread ordeal, and have moreover to pay a hundred dollars to the Provincial Medical Council.

Hoping this may serve to correct any wrong impression which your correspondent's letter may have created with regard to the right of English medical qualifications, I am, Sirs, yours obediently,

Victoria, British Columbia, July 24th, 1889. CORYLAS.

MIDWIVES' INSTITUTE AND TRAINED NURSES' CLUB.

To the Editors of THE LANCET.

SIRS,—Will it be asking too great a favour to beg you to make known to medical men who may have copies of works upon midwifery and surgery for which they have no further use that such would be most gratefully received by the Midwives' Institute and Trained Nurses' Club, 15, Buckingham-street, W.C., if they are forwarded to the secretary? This institution endeavours to give all possible help to those midwives who are preparing themselves for the Obstetrical Society's examination, and all works on midwifery are invaluable to these women, many of whom have very small means, and consequently their education is a very severe strain upon their incomes. Frequent requests come from country members to the librarian to send them the different standard works for their studies, and the Institute cannot meet the demand, as they have a very limited supply of these books, although some medical men have generously presented their works to the institute. If you would be so good as to help the institute by making known this need, you would confer a great favour upon the members, and help a body of women who are striving to prepare themselves thoroughly for their responsible position.

I am, Sirs, yours obediently,

MARGARET R. NICHOL,
Secretary to the Midwives' Institute and Trained
August, 1889. Nurses' Club.

FIXING METAL RINGS ON NIPPLES.

To the Editors of THE LANCET.

SIRS,—It has been pointed out to me that there exists in certain countries a practice of fixing a metal ring on the human nipple. The information was derived from the *English Mechanic* (see March 29th, p. 99; April 5th, p. 118; May 3rd, p. 199; May 10th, p. 222; July 26th, p. 460). I shall feel obliged if you will allow this letter to appear in your columns, in order to ascertain if any member of the profession be cognisant of the practice. I am, Sirs, yours truly,

Aug. 8th, 1889. H.

OLD "REMEDIES" FOR HYDROPHOBIA.

OUR readers may be interested in perusing the following formulæ, which have been strongly recommended to us as efficacious in the treatment of rabies. There is a flavour of antiquity about their composition which brings to mind the days when faith in the efficacy of drugs and in length of prescription went hand-in-hand. It is pleasant to think that there are some even now who cling to old beliefs, which with most of us have been shattered by the ruthless progress of science.

"℞ Hydrargyri perchloridi, grana decem; potassii iodidi, grana octo et viginti; aquæ destillatæ, minima octoginta; pulveris gummi opii, grana decem; butyl-chloral hydratis, grana quadraginta; extracti cannabis indicæ, grana octo; pulveris gummi resinæ asafœtidæ, grana octoginta; pulveris foliorum digitalis, grana sedecim; pulveris gummi resinæ guaiaci, grana octo et quadraginta; pulveris gummi acaciæ, grana viginti; pulveris gummi tragacanthæ, grana duo; pulveris radicis glycyrrhizæ, grana quatuor et viginti; aquæ destillatæ, quantum sufficiat ut fiat massa pilularum, bene misceatur. In pilulas centum æquales dividatur. Harum capiatur una omni mane (cum misturæ dosi una) per tres dies, duæ quotidie per tres dies, tres per tres dies, quatuor per quatuor dies, quinque per quinque dies. Postea doses ad hunc modum minuantur—quatuor per quatuor dies, tres per tres dies, duæ per tres dies, ad postremum una per tres dies capiendæ."

"℞ Decocti sarsæ compositi concentrati (Pharmacop. Brittanic.—una pars ad septem partes parandas), uncias fluidas duodecim; potassii iodidi, grana trecenta et nonaginta. Misce fiat mistura. Cochleare minimum ex duobus aquæ cochlearibus magnis ter die ante cibos capiendum."

"℞ Hydrargyri perchloridi, grana quindecim; aquæ destillatæ, unciam fluidam dimidiam; aquæ calcis, unciam fluidam. Misce fiat solutio. Signetur "ad usum externum." Caute servetur ad canum morsuum cauterium. Caute injiciatur cum syringa parva continenti drachmam dimidiam. Vide ne penetrat syringæ punctum ad una lacera vulnera. Faciat duas injectiones statim vel quam primum post morsus recipiendos, et eas reficiat bis, per duas horas."

To this it may be well to append another formula for the cure of hydrophobia, which we have also received from a correspondent, who states that it was copied from an entry in a parish register, bearing the date Sept. 14th, 1765.

"An infallible cure for the bite of a mad dog, brought from Tonquin, China, by Sir George Cobb:—20 grains of native cinnabar, 20 grains of factitious cinnabar, 16 grains of musk. This was to be mixed with a small teacup of arrack, rum, or brandy. Persons who even had the symptoms of madness on them are said to have been cured by it."

Celt.—Personal canvassing is sometimes specifically forbidden in such cases. If it is not so in this case, we see nothing objectionable from a medico-ethical point of view in the course our correspondent mentions, so that it be taken with due respect to other candidates.

An M.R.C.S.—We will communicate with the writer of the letter referred to.

"LIFE IN TASMANIA."

To the Editors of THE LANCET.

SIRS,—In answer to "Emigrant," whose letter under the above heading appeared in your issue of Aug. 10th, allow me to state that during the winter before last I spent three months in Tasmania, and, as far as I could ascertain, there were no openings at all in the island for medical men. In Hobart, the capital, there were twenty medical practitioners. Launceston, the only other town of any size, had ten, and every little township—or village, as they would be termed here—had its doctor, sometimes two. People have, as a rule, rather vague ideas of the size of Tasmania. As a matter of fact, the entire population is only 60,000; so the scope for practice is very limited, the fees are low as money goes there, and there are plenty of good men. An M.B. of London was holding the post of house-surgeon to the hospital in Hobart at the time I speak of. Your correspondent would, I am sure, find it very difficult to make anything of a practice. In answer to his question as to the life one leads there, I may say that in the towns it is much the same as in English towns of similar size; in the country it means entire absence of social pleasures and long distances to travel over very indifferent roads, or "tracts," as they call them. I have ridden thirty-five miles, mostly through bush, to see a patient in conjunction with a friend of mine practising in the country.

In conclusion, I would advise your correspondent to think well before deciding on Tasmania. New Zealand and Australia are both getting filled up, though not to the same extent. The best openings, I believe, are to be found in the country parts of New South Wales. Of course, if "Emigrant" is going solely for health, it is a different matter—*necessitas non habet leges;* but, otherwise, I would advise him to stay at home. I am, Sirs, yours faithfully,

Aug. 14th, 1889. A. CROSBEE DIXEY, M.R.C.P.

Iain.—Only, we believe, from the Liverpool papers, which gave extremely full reports.

Mr. John J. Walsh.—Dr. Goodhart's book will probably suit our correspondent.

Peak.—We are unable to trace the reference mentioned.

INSANITY AND MUMPS.

To the Editors of THE LANCET.

SIRS,—Dr. R. Percy Smith, at page 265, reports two cases of acute mania associated with mumps. Dr. Williamson, in your journal, March, 1886, page 487, records a similar case that proved fatal, and in the Medical Digest, Section 813 : 1 (Appendix), among the symptoms accompanying this affection delirium is noted.

I am, Sirs, yours truly,

Boundary-road, N.W., Aug. 10th, 1889. RICHD. NEALE, M.D.Lond.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

ABSTRACT OF THE

Address in Medicine,

Delivered at the meeting of the British Medical Association, Leeds,

BY J. HUGHLINGS JACKSON, M.D., F.R.S.

ON THE COMPARATIVE STUDY OF DISEASES OF THE NERVOUS SYSTEM.

AFTER thanking the President and Council of the Association for the honour conferred upon him by their request to deliver this address, the lecturer dwelt upon the necessity of having generalisations and working hypotheses for the classification and organisation into higher knowledge of the multitudes of accumulated facts, and continued as follows.

We have, ready made for us, so to speak, the hypothesis of evolution—one verified in numerous different cases. Huxley writes: "The peculiar merit of our epoch is that it has shown how these hypotheses [one of which is the doctrine of evolution] connect a vast number of seemingly independent partial generalisations; that it has given them that precision of expression which is necessary for their exact verification; and that it has practically proved their value as guides to the discovery of new truth." The indirect value of the doctrine of evolution to clinical medicine is very great indeed, and before long it will be without doubt directly helpful. We should also attempt a parallel study of diseases, as they are dissolutions—that is, reversals of evolution. Precise generalisations of great value would result from this method. The greatest merit of Gaskell's work consists in his having set many things long ill-assorted in realistic order. By so doing he will have put a stop to certain loose explanations in which the sympathetic figures. Generalisation, as here applied, is the classification of things which are for the most part very different by some fundamental peculiarity each of them has. I will give a series of illustrations of the method spoken of, because it is one I follow largely in this address.

1. A patient of mine had lost one hand, but, as is most often the case, he had representing it a phantom hand; this was always in such position as if encircling a vessel; the member had been blown off when he was holding a cylinder to be charged with an explosive.

2. An aphasic patient of mine frequently uttered, on being questioned, but with no relevance to anything going on, "Come on," or "Come on to me." He was a signal-man, and had been taken aphasic and hemiplegic on the railway in front of his box; the presumption is that he was saying, or was about to say, those words when taken ill.

3. An epileptic patient told me that his first fit occurred when he was a soldier, and at the very time he was "numbering off"; after every subsequent fit, and before regaining consciousness, he used to count; this we observed when he was in hospital.

4. A woman I was asked to see in a surgical ward in the London Hospital, who had fractured her skull by a fall when laying down oil-cloth on a staircase, kept, during partial unconsciousness a few hours before death, manipulating the counterpane of her bed. We supposed this to be a sort of continuance of the action of laying down the oil-cloth; the patient desisted, for a time at least, when the nurse assured her that "it was properly laid."

The consideration of these illustrations, which appear incoherently grouped, is to make a basis for the discovery of the reason why there is a fixation of states, normally temporary, upon the sudden occurrence of lesions of the nervous system; very different cases are chosen in order to make the basis a broad one. The comparative study of nervous diseases—the study of them as dissolutions—is a process of generalisation. The symptomatology of each must be regarded as the result of a flaw in an evolutionary whole, and should take into account the evolution going on in the undamaged remainder of the nervous system. A great part of the symptomatology of ocular paralysis is owing to over-activity of perfectly healthy nervous arrangements, and the same is true in a case of insanity, the erroneous projection and diplopia in the first, and the illusions, delusions, and all other positive mental symptoms in the second, resulting from the activity of undamaged parts. (1) Evolution is a passage from the most to the least organised, high organisation meaning perfection of union and certainty of action of nervous elements with one another. In this sense the highest cerebral centres are the least organised (the "most helpless centres"), although they are the most complex; whereas the lowest centres are the most organised, although the least complex. In other words, (2) the evolutionary ascent is from the least to the most modifiable. If the highest entres were not modifiable, we should be very simple machines; we should make no new acquirements. If the lowest ("vital") centres were to become as modifiable as the highest are, life would cease. It is only another aspect of this to say (3) that the passage is from the most automatic to the most voluntary; equivalently it is (4) from structures inherited most nearly perfected, such as the cardiac centres in the medulla, to those of the highest nervous arrangements of the highest centres, which are only incipient nervous structures, and which are evolving during the latest new mental states. (5) The process of evolution is from the simple to the complex; (6) from the general to the special. Reversals of evolution are effected by pathological processes, and are called dissolutions. They are reductions from the least organised &c. towards the most organised &c. In regard to the periphery, in most cases of progressive muscular atrophy, the muscles first morbidly affected are the small muscles of the hand, and in most cases of Duchenne's bulbar paralysis the tongue is first invaded. In both cases the special parts fail first. Going higher, it is plain that hemiplegia from disease in the mid-cerebral region is a failure in the order from "most voluntary" towards most automatic. Chorea and paralysis agitans illustrate dissolution in the same manner as hemiplegia, and the various phenomena of aphasia illustrate this still better. Dr. Donald MacAlister, in his admirable Croonian Lectures, pointed out that the febrile process exemplifies dissolution. "In the ascending scale of evolution we seem to rise from the thermolytic to the thermogenic, and thence to the thermotaxic nervous system." Fever is a process of dissolution, and recovering from it one of re-evolution. Probably all cases of insanity illustrate dissolution. "That general paralysis," Dr. Savage writes, "affects first the highest intellectual and motor acquirements is undoubted. Both Dr. Maudsley and I have independently taught that in this progressive degeneration the last and highest acquirements 'fail first.'" An entirely parallel state is seen in the symptomatology of drunkenness: the muscles of the tongue, the eyes, the face, and the limbs become successively unmanageable; and under the same circumstances muscles which have a double office, such as those of the chest, lose their voluntary and retain their involuntary motions; the force of the arms is gone long before the action of breathing is affected. We see, not dissolution, but evolution, illustrated by certain surgical cases, by the order of persistence of spectral representations of parts lost by amputation. Weir Mitchell writes: "The limb is rarely felt as a whole; nearly always the foot or the hand is the part more distinctly recognised, and on careful questioning we learn that the fingers and toes are readily perceived; next to these the thumb; then more rarely the ankle or wrist; and still less frequently the elbow and knee. Very often some fingers are best felt, especially the forefinger." This, the order in which the lost parts remain most vividly represented in consciousness, is almost exactly the order in which the parts physical do fail in dissolution of the nervous system. Speaking generally, the hemiplegic man is reduced to a more automatic condition of movement, the aphasic to a more automatic condition of language, and the insane man to a more automatic condition of mind.

Dissolution is exemplified in each of the following very different symptoms. 1. Most epileptiform seizures commence in the thumb or index finger, or in both; these digits are the most special parts of the body. 2. The words most often left to an aphasic, who is for the rest entirely speechless, are "yes" or "no," or both; these "words," as I called them, are the most general of all propositions. 3. The aphasic may be unable to put out his tongue when told, although he moves it well in other ways: loss of the "most voluntary"

Digitized by Google

movement, with persistence of the more automatic movements of that organ. 4. In what is called word-blindness there is inability to recognise the latest learned, and very arbitrary "objects," letters, and words, whilst the recognition of objects, properly so-called, is unimpaired or comparatively so. 5. In early stages of atrophy of the brain—say in that occurring so often in hemiplegia in men past middle age—there is defect of memory for recent events, with seemingly good remembrance of long past circumstances, and there is at the same time loss or defect of the "finest" and latest acquired emotions, with obtrusion of the coarser and earlier acquired.

As to the evolutionist's measure of mind, a scientific standard ignores superior and inferior, as these terms are ordinarily used with regard to men's minds. Higher races of men and adults have the latest acquired faculties, and these, according to Spencer, are, intellectually, the power of abstract reasoning, and, emotionally, the sentiment of justice. In the cases of atrophy of the brain recently instanced, there first occurs defect of the two "latest" faculties I mentioned; the patient easily becomes confused by consideration of things of a little complexity, and of which the elements are not before him, and is often peevish and selfish. It may be said that the symptoms from morbid changes in the cerebellum do not accord with statements made as to the process of dissolution. I believe that all the skeletal muscles are represented in the cerebrum in one set of movements, and that all of them are represented in the cerebellum in another set of movements. In rough and only partial statement, the order of representation in the cerebrum is of movements of the arm, leg, and spine. This agrees with a popular doctrine, for the order is that of the degree in which the three parts of the body are "under the command of the will." The order of representation in the cerebellum is of movements of the spine, leg, and arm. This accords with the current doctrine that the cerebellum coördinates movements of locomotion. The arm then is the most special part in the cerebral series, and fails first in disease of the brain proper; and the back is the most special part in the cerebellar series, and fails first in disease of the cerebellum.

By the aid of the doctrine of evolution we shall discover a harmony or rational parallelism between (1) psychology, (2) the anatomy and physiology of the nervous system, and (3) that important part of clinical medicine which deals with diseases of this system. It will help us towards a comparative study of all diseases of the nervous system, and particularly of insanity. The doctrine of evolution implies that the whole nervous system has a sensori-motor constitution. I extend this to the highest cerebral centres, which represent parts of the body as certainly as the lumbar enlargement does; they are evolved out of lower centres, which everybody admits do represent parts of the body. No one denies that the highest centres contain sensory elements; no one denies that very many, if not all, parts of the body are represented sensorily in the "organ of mind." But there seems to be great objection to their representation motorily in that organ. The præfrontal lobes are said to be the "mental centres." That they are a great division of these I admit, but that they are motor also is shown by the appearance of descending degeneration as far as the medulla after their ablation in monkeys.

I will here state in outline what I believe to be the hierarchy of the motor centres. 1. The anterior spinal horns and their homologues higher up (nuclei of motor cranial nerves) are the lowest motor centres (both of the cerebral and cerebellar systems). These lowest motor centres, with the corresponding sensory centres, make up the lowest level of evolution of the central nervous system. 2. The convolutions of the Rolandic region are the middle motor centres of the cerebral system. With the corresponding sensory centres, they make up the second or middle level of the central nervous system. 3. The præfrontal lobes are the highest motor centres of the cerebral system. With the corresponding sensory centres, they make up the third or highest level of the central nervous system—that is, the "organ of mind." Movements rather than muscles are represented in the central nervous system. The movements effected by, say, thirty muscles of the hand are represented in the nervous centres in thousands of different combinations; just as so many chords, musical expressions, and tunes can be made out of a few notes.

I now speak of the representation of the muscles of the hand in the three orders of motor centres just spoken of: 1. In some lowest motor centres (anterior horns), which are evolved out of the muscles of the hand, the muscles are represented in numerous different combinations, as simple and very general movements. 2. In the middle motor centres (Rolandic region) which are evolved out of the lowest motor centres, the same muscles are represented (re-represented) in still more numerous different combinations, as complex and special movements. 3. In the highest motor centres (præfrontal lobes), which are evolved out of the middle motor centres, the same muscles are represented (re-re-represented) in innumerable different combinations, as most complex and special movements—the last representative of the "finest" movements of the hands in the anatomical substrata of tactual ideas and of other mental states.

The highest centres ("organ of mind") have no other function than that of representing parts of the body. Bearing in mind the subordinate centres, they may be said to represent parts of the body triply indirectly. Function is a physiological term, and not applicable to states of consciousness, such as attend functioning of the highest cerebral centres. We can only affirm concomitance, and the association is as yet inexplicable. According to the late Professor Clifford, between the physical facts and the mental facts there is a parallelism, but no interference of one with the other. It is not the mind, but the physical basis of mind, which is a product of evolution, and the sensori-motor hypothesis is not put forward to attempt to explain psychical by anatomico-physiological states. I contend that the highest centres represent all parts of the body supplied by nerves; not only sensory parts, but limbs and internal viscera. The highest centres are centres of universal representation or coördination. Dr. Mercier, dealing with coma, writes: "Thus we arrive at this most important conclusion—that the highest nervous processes, which form the substrata of the most elaborate mental operations, represent at the same time, not only the most elaborate forms of conduct and muscular movements, but also *every part of the organism*" (italics in original) in some degree. Ribot, writing on Personality, says: "Nous pourrons dire que le couche corticale représente toutes les formes de l'activité nerveuse—viscérale, musculaire, tactile, visuelle, significatrice." The lowest level (pons, medulla, and cord) represents all parts of the body; certainly motor effects in nearly all parts of the body are produced by discharges of the "motor region." I am only going a step further when I suggest that the highest level is also universally representing. A higher level of evolution is, so to put it, the lower "raised to a higher power." The phenomena of an ordinary epileptic fit seem to me to accord with the hypothesis of sensori-motor constitution and universality of representation. Cessation of consciousness results from a discharge beginning in some part of the physical basis of consciousness. Effects which are motor, or their equivalent, are seen in all parts of the body. In slight fits the effects are widely distributed, including pallor of face, increase of saliva, arrest of respiration, and emission of urine. The epileptic discharge differs from an ordinary one in being sudden, excessive, and rapid, and also in starting in some small part of the highest centres (a "discharging lesion" or "physiological fulminate"). Artificially induced discharges in the Rolandic region produce effects in all parts of the body, including the viscera; for if curara be given to a dog, and the sigmoid gyrus faradised, the fit is limited to the organic parts, and includes increased flow of bile, paling of the kidneys, and contraction of the spleen. That universal effects are so produced gives some countenance to the supposition that the anterior highest motor centres are also universally representing. To state this in another way: Whilst a man is having states of consciousness (willing, remembering, reasoning, and feeling), there occur correlatively slight discharges of nervous arrangements of his highest centres representing the whole of his body. Here is best seen the harmony of psychology with the anatomy and physiology of the nervous system, and here lies the basis of a comparative study of insanity (diseases of the highest centres) with diseases of the lower centres. When we explore an object the skin of our fingers and the muscles of our hands are engaged. During the actual exploration there is a vivid mental state; in thinking of it when absent there is a faint mental state. In both cases there is sensori-motor action, in both the same nervous arrangements of the highest centres. If the discharge were sudden, excessive, and rapid, there would be a miniature epileptic fit, with tingling referred to the fingers, and convulsion of the hand.

Digitized by Google

Accepting, provisionally, the conclusion that the anatomical substrata of will, memory, reason, and emotion represent together all parts of the body, sensorily and motorily, how is it that such apparently different phenomena as convulsion, with cessation of consciousness and insanity, result from morbid affection of the "organ of mind"? Often enough there is the sequence of an epileptic convulsion with loss of consciousness and then post-epileptic mania. Moreover, I believe that paralysis also results from negative states of these centres; it exists in temporary post-epileptic insanities—indeed, in every case of insanity. According to the severity of the paroxysm, there is either mania or coma, which is acute temporary dementia rapidly produced. The negative affection of consciousness in the comatose patient implies a correlative negative state of more or less of his highest centres, which causes paralysis. That there is some universal paralysis after a severe epileptic fit accords with the hypothesis of universal representation by the highest centres, and is in harmony with the universality of the convulsion in the prior paroxysm. That there is paralysis is indicated by lateral deviation of the eyes and alteration of the deep reflexes observed after such seizures. The loss of power in post-epileptic coma is probably distributed over the highest, middle, and lowest centres.

From the conclusion about post-epileptic coma, we make the hypothesis that there is a widespread or universal paralysis in all cases of insanity, corresponding with the universality of representation by the highest centres, which are here certainly diseased. In all cases of insanity both the mental and physical conditions are duplex—positive and negative. The defect of consciousness and the positive mental symptoms vary inversely, and either may attract exclusive attention. But surely these positive symptoms of themselves imply the coexisting negative states of some non-recognition and some non-reasoning—that is, they really imply some coexisting defect of consciousness. Regarding the physical condition of the highest centres, the negative affection implies some temporary or actual loss of function, implying paralysis; the positive, some function over-active from loss of control or counterpoise. The delusions of insanity signify evolution going on in the remains of a mutilated nervous system, as certainly as the beliefs of sanity signify evolution going on in an entire nervous system. In post-epileptic mania, the positive symptoms are due to a great hyper-physiological activity of the healthy third layer, which are no longer controlled by the highest two layers of the highest centres. When a rabbit's cerebrum is cut out the animal is demented. But movements of every part of its body can be evoked by appropriate incitations. Nevertheless, I declare that the animal is paralysed. It retains all simple movements represented on the lowest level of evolution, which is pretty much all that is left of its cerebral series. But it has lost all the more complex movements, those which we should distinguish as the physical aspect of conduct, and is therefore universally paralysed. So the incoördination which results from a tumour of the middle lobe of the cerebellum is referable, not to the direct influence of the lesion, but to the over-activity of perfectly healthy nervous arrangements, which are doing more than their normal share of work, owing to loss of some movements of the spinal muscles. In comparing such a case with one of hemiplegia, the comparison is not one of incoördination with hemiplegia, but of loss of movements of the spinal muscles with loss of movements of the limbs. I submit that the formula describing all incoördinations with negative lesions of the nervous centres is that there is, negatively, loss of some movements, paralysis (this alone being the result of pathological change), with, positively, forcing of some other movements of the same muscle. In saying this, the assertion that much of the symptomatologies of nervous diseases is owing to activities or over-activities of healthy nervous elements is implicitly reiterated. I believe that in what is commonly called tremor in a case of disseminated sclerosis—say of an arm—there is paralysis in the sense of loss of some movements of the limb; the tremor itself is owing to the fact that the excursions of the limb have to be effected by fewer, and presumably less fit, movements than normal. Observe, there is loss of some and retention of other movements of the same muscles. The movements by which the limb carries, although erratically, a cup to the mouth are not blameworthy; they are the best in the evil circumstances—the next best to the normal; they are produced, I suggest, by discharge of healthy nervous arrangements. When a man has paralysis of the extensors of the forearm his grasp is weak and the hand moves clumsily in all its uses. But no one thinks of blaming the flexors for the weak grasp and for the clumsy operations of the limb; the flexors are acting faithfully; what they do is badly done because the extensors will not co-operate. So I suggest that, in the kind of tremor spoken of, the fault is that, certain movements being lost, they no longer co-operate with others which, being unaided, move the limb erratically; the real fault, what the pathological change causes, is paralysis. That a patch of sclerosis, if it be an absence of proper nervous elements, can cause any movements, good or bad, is an impossible thing; the tremor has, however, been ascribed to imperfect function of intact axis cylinders in the parts sclerosed.

I have long held that the lesion in cases of aphasia produces paralysis in the sense of loss of complex &c. movements of the articulatory muscles. It may, however, be urged that the articulatory muscles move well; so they do in simple operations, but they never move so as to make articulations (syllables). The experiments of Semon and Horsley demonstrate, in one case at least, that there may be loss of some movements of a muscular region, with persistence of so many other movements of that region, that no disability in the working of the muscles is discoverable. (These experiments are a strong confirmation of Broadbent's well-known hypothesis, for one case at least.) In cases of pernicious diabetes the lesion is supposed to be of a certain part of the great vaso-motor centre, the disease producing nothing but paralysis of the hepatic arterioles. As a result of local paralysis from lesion of part of the spinal system, it is comparable to ordinary progressive muscular atrophy or anterior polio-myelitis. I suggest that the xerostomia described by Hutchinson and Hadden is also a paralysis, owing to a negative lesion of the centres for the motor nerves of the salivary and other oral glands. The essential thing, that which disease, in the strict sense of pathological change, produces in cases of insanity, "disorders of coördination," with negative lesions, tremor, aphasia, pernicious diabetes, and xerostomia, is paralysis. I submit the hypothesis that (1) progressive muscular atrophy, (2) paralysis agitans, and (3) general paralysis are homologous diseases. The comparison and contrast is not of wasting of muscles, tremor, and a negative psychical defect; but there is loss respectively of (1) simplest, (2) more complex, and (3) most complex movements of the hands. The comparison is of three cases of paralysis. The lesion is supposed to be wasting of cells, in the order from smallest towards largest, of lowest, middle, and highest motor centres respectively. 1. In progressive muscular atrophy there is loss of simplest movements of hands, of those represented in the lowest motor centres. The muscles are cut off from the influence of the central nervous system and waste. Were there not, however, retention of more complex middle and highest centres, the patient could neither think nor dream of moving the part, and would have no physical basis for tactual ideas. 2. In paralysis agitans there is, negatively, loss of complex (middle) movements of the hand, and at the same time, super-positively, over-development of simplest movements. 3. In general paralysis there is loss of some of the most complex ("finest") movements of the hands, those represented in the highest motor centres, of those entering into the physical bases of tactual ideas, and of other mental states. Here there is retention of less complex (middle), and of simplest (lowest) movements. The negative psychical defect in general paralysis is wider than that answering to loss of motor elements in the highest centres representing the hand. Yet, if Spencer be right in saying that all other ideas have to be translated into tactual ideas, to lose these is to become imbecile. I ask you to bear in mind the suggestion that the positive mental symptoms correspond to activities of healthy nervous arrangements. If so, we have nothing to do with them at the time we are dealing with the effects of pathological processes. Most mentation is carried on in visual and tactual ideas, and by aid of words. To have negative affection of consciousness is, therefore, to have especially loss of these three; and thus it implies that there is correlatively a negative state of their sensori-motor bases. In general paralysis, the lesion, if of the highest motor centres, is of the motor elements in those sensori-motor nervous arrangements—is loss of more or fewer of the most complex ocular, manual, and articulatory movements; the lesion, therefore, produces paralysis in the sense of loss of the "finest" movements of the three parts.

ABRIDGED REPORT OF AN

Address in Psychology,

Delivered at the meeting of the British Medical Association, Leeds,

BY SIR JAMES CRICHTON-BROWNE, M.D., &c.,
LORD CHANCELLOR'S VISITOR IN LUNACY.

TAKING for his text the Hygienic Uses of Imagination, the lecturer spoke as follows:—

The 84,407 insane persons who were in asylums of one kind or another on Jan. 1st last, and under the care of specialists, had all been consigned to these establishments on the evidence of medical men who were not specialists. The admissions to asylums during the previous year, 1888, had numbered 20,098; and calculating that of these 2850 were private cases, in which two certificates are required, and 17,248 pauper cases, in which one suffices, we arrive at the conclusion that 22,948 certificates of insanity—certificates, I need scarcely say, involving nice considerations and grave consequences—were granted during the year by medical men who are not specialists. The Lunacy Acts Amendment Bill, which is awaiting the Royal assent, will, when it becomes law, to some extent relieve medical men from the apprehensions which have hitherto attended the signing of lunacy certificates, for merely vexatious legal proceedings, founded on such certificates, will henceforth be no longer possible; but no Act of Parliament can in any way diminish the sense of responsibility attending a step entailing deprivation of freedom, some opprobrium, and far-reaching disabilities; and the certification of the insane must, therefore, always remain an anxious duty to general medical practitioners, and bring home to them the truth that they have an immediate concern in medical psychology. But this immediate concern is, indeed, brought home to them, as a rule, in each case long before the question of certification arises, for insane persons are only removed to asylums or brought under official cognisance when their mental disorder has reached a certain pitch of intensity or assumed a dangerous type; and a large majority of the 20,098 patients admitted into asylums last year must have been for a considerable period prior to that event under the care and treatment of general medical practitioners. ..... Besides the badly managed brains that are sent into asylums for safe keeping or repair, there are in this country in every stratum of society, large numbers of blemished brains that perform their functions irregularly, have no delight to pass away the time, and are centres of misery and annoyance to their owners and all connected with them. These blemished brains in which aberrant mental action may stand alone or be bound up with the phenomena of every variety of nervous disease, perpetually remind the general practitioner by their appeals to him for commiseration and help, that he cannot ignore medical psychology. .....

But the general medical practitioner, in the performance of his daily duty, must have regard not only to the psychical symptoms of corporeal disease, but to the psychical conditions and experiences out of which corporeal diseases grow, and by which their course may be beneficially or injuriously affected. He has to determine the part played by mental overstrain and worry in the production of degenerative changes in old and young; he has to watch the destructive ravages of violent passion and emotion; and he has to endeavour to abrogate the causes of mental agitation or failure, and impart a healthy tone to the system by instilling confidence and hope. And he is, perhaps, never more a medical psychologist than when he is practising what is called moral treatment, and is by his manner, demeanour, and well-chosen words driving out fear, calming turbulent feeling, and encouraging self-control. His success or failure as a practitioner will, indeed, often depend as much on his expertness in this moral treatment—that is to say, on his acumen as a medical psychologist—as on his manual dexterity or skill in simples. It would seem, then, that medical psychology meets the general practitioner at every turn, and that mind in its relations to nervous activities must necessarily engage his attention to some extent. .....

Mind still remains to us an impenetrable mystery, "having neither beginning of days nor end of life"; and to speak of it as if it were an exhalation of brain matter, and of brain as if it were a solidification of mind, is to fall into the grossest error. Materialism is simply a logical blunder, springing out of indiscrimination between the objective and subjective. Matter, which signifies what is the object of our knowledge or that which can be known, can never by gradual transitions become subjective and knowing, stripping itself of its essential attributes and assuming those of its opposite; and materialism is therefore founded on a confusion of ideas. At first, it is assumed, all was matter or object, and in the fulness of time matter came to know itself, and object by fissiparous division gave origin to subject. But object cannot exist without subject, and matter *minus* spirit is a nonentity, and therefore materialism and idealism, in the ordinary acceptation of these terms, are equally self-contradictory. .....

But although the real nature of the relation between mind and brain is unthinkable, it is convenient to have a working hypothesis on the subject, and hence several metaphysical versions of it have been advanced and more or less widely accepted. To three of these, which may be called the intersectional, the identical, and the parallel theories, I may briefly allude. It has been suggested that the brain is an internal periphery, as it were, upon which psychical forces impinge, just as physical forces impinge on the external periphery of the sensory nerves and nerves of special sense. It has been suggested, again, that the activities of the mind and brain are the obverse and reverse aspects of one and the same thing, so that there is nothing to explain. And it has been suggested also that there is a parallelism between mental and cerebral activities which, although entirely different and never interfering with each other, yet invariably occur in correlation. This last theory, the theory of parallelism, or of concomitance as it is also called, which supposes that mental states arise during functional states of the brain, from which, however, they are totally dissimilar, is that which has been adopted by Herbert Spencer, Max Müller, Tyndall, Hughlings Jackson, and others of our foremost thinkers; and the first theory—the theory that the mind acts through the nervous system—has been pronounced the least tenable, because by it an immaterial agency is supposed to produce physical effects. .....

Whatever theory we may approve as to the relation between mind and matter, we must take care not to confine that relationship within too narrow a compass. No doubt it is in the highest and dominating centres of the cortex, in which are finally repeated all lower nervous arrangements, so that they become the unifying centres of the organism, that those functional activities upon which psychical states attend are to be sought, but it must be firmly maintained that it is the whole body that is the organ of mind. A brain that is detached from a body is no longer an anatomical substratum of thought, and there are grounds for believing that what may be described as a radiation of consciousness is perpetually taking place. The difficulties in the way of accepting the current theory of sensation has led one of our most philosophical anatomists, Professor Cleland, of Glasgow, to argue that "consciousness extends from its special seat as far as there is continuity of the impressed condition"; or, in other words, that when an irritation is applied to a nerve extremity, as in the finger or elsewhere, the impressed condition of the nerve travels upwards, as is generally understood, but exists for at least a moment along the whole length of the nerve, and that as soon as there is continuity of the impressed condition from the extremity to the brain, consciousness is in connexion with the nerve, and is directly aware of the irritation of the nerve extremity. Functional continuity between nerve extremity and brain is proved to be necessary to sensation; while, on the other hand, the existence of distinct unbroken routes of communication between them is highly improbable; and seeing that functional continuity is of itself sufficient to explain the phenomena, we are not entitled to assume the existence of distinct routes, as has hitherto been done. ..... But whether or not we accept the view that the mind recognises an irritation at the part of its application according to its character, we shall do well very strenuously to oppose a too rigid circumspection of psychical states in the cerebrum itself. We all know that electrical stimulation of the præ-frontal lobes in animals is not followed by muscular movements, and that, as Ferrier has shown, their extirpation in monkeys is followed, not by any sensory or

Digitized by Google

motor disturbance—the senses, emotions, and power of voluntary motion remain intact,—but by an alteration in character and behaviour, which betokens a loss of the faculty of attention and intelligent observation. But Hughlings Jackson teaches that the whole of the frontal lobe is chiefly motor in its functions; and Ferrier and Gerald Yeo have demonstrated that some movements, such as the lateral movements of the head and eyes, are represented in the præ-frontal division; and attention and intelligent observation, if localised here, do not by any means exhaust psychical activities. These are not to be pent up in any corner of the brain; and to call the frontal lobes psychical or ideational is misleading. Perhaps, even as regards sensory and motor centres in the brain, we have attempted too sharp a demarcation and too much exclusiveness. Some motor centres apparently to some extent overlap each other; some movements seem to have a widely-diffused representation. Gowers has given reasons for thinking that motor centres also possess some sensory functions, and has been confirmed in this position by the observations of Nothnägel, Exner, and Luciani. Then it is probable that we have not by our experiments demonstrated all the functional activities of any part of the cortex. That large area, the præ-frontal lobe, does not in any way respond to electrical stimuli, and affords only vague and problematical indications when submitted to ablation; but that it possesses important functions is indubitable, and we are not entitled to deny that functions kindred to those of the præ-frontal lobe, beyond the reach of anything but vital stimuli, are possessed by regions of the cortex, electrisation of which evokes cruder and more accessible sensory and motor functions. Much and prolonged observation and experiment are still requisite in order that we may attain to anything like a complete knowledge of cerebral architecture, and meanwhile we cannot be too careful in assigning sites to psychical activities. .....

But I wish to direct attention more particularly to a mental faculty that has certainly no narrow local habitation in the brain—to imagination, which has been called the noblest attribute of man, and which arises during re-excitations in ever-varying coalitions of permanent cell modifications in sensory and motor centres. I wish to impress upon you that this psychical power has its hygienic uses which neither the medical psychologist nor general practitioner can afford to neglect. Now, imagination awakens and calls forth from their organic registers the records of movements and sensory impressions. The impressions of sense are strong, the revivals of memory are faint, and the images of imagination may be said to occupy an intermediate position. Sometimes, indeed, in the coarse frenzy of the madman, and even in the fine frenzy of the poet, the molecular thrill of the idea revival becomes so intense that it overleaps the boundaries of the cerebral cells, and vibrating to the peripheral expansion of the nerve, reinduces exactly the conditions of the original sensation, when hallucinations arise and a counterfeit is mistaken for reality. But in the less violent workings of imagination, the revivifications which it effects are practically confined to cerebral centres, and, although more clear and luminous than the reproductions of memory, are surrounded by a nebulous haze that distinguishes them from the communications of sense. But the essence of imagination lies not in the superior brightness and clearness of its representations when compared with those of recollection, but in the novelty and supersensuous suggestiveness of the combinations by which they are made up. Its images, in which are brought together in harmonious blending things new and old, are not reached by elaborate composition, but by a flash of intuitive perception; they are not built up, and do not even grow by slow and silent increments, but spring into being fully formed. ..... I do not propose to say anything about the operation and influence of the imagination when resting on intuitive beliefs and historical facts, and, stirred by the most earnest cravings of our nature, it mounts into faith and reveals to us "the substance of things hoped for, the evidence of things not seen."..... As a matter of fact, faith has an overpowering influence on individuals and nations, an influence that is essential to their health and well-being, for whatever disasters perversions of faith may have entailed, its normal action is wholesome and hygienic. ..... But it would be neither expedient nor possible for me to trace out here the bearings of faith on corporeal and mental welfare, nor must I even pause to bestow the notice they deserve on those excrescences on faith known as faith-healing and Christian science, which have a certain vogue at present and fall legitimately within the scope of medical inquiry..... Their professors, like empirics of all sorts, have wrought modern miracles on hypochondriacal men, who have fallen into drivelling egotism; on hysterical girls, who have entertained demons not unawares; and on a few sincere but highly sensitive persons, who can pass at a touch out of one allotropic state of the nervous system into another. But the small good they have done these has been more than counterbalanced by the mischief they have wrought in encouraging imposture, in postponing medical treatment where it is needed, and in inducing in their adherents, now a large class, an attitude of mind that is debilitating and conducive to the incursion of disease..... Let the faith-healers and Christian scientists commence with skin diseases—woo the acarus scabei from its burrow without aid of brimstone, arrest lupus, and wipe out a nævus,—and we shall then be ready to follow them with some hope in their campaign against hidden maladies. ..... But my theme now is not faith-healing or faith—which faith-healing travesties,—but the secular imagination and its hygienic uses, my aim being to convince you that it is one of the most effectual of those psychical agencies by which we may modify the conditions of health and disease, and deserves, therefore, the attention of the general medical practitioner in his capacity as a medical psychologist.

Now, the scientific use of the imagination in relation to medicine may be properly included in its hygienic uses, for that faculty is the main instrument of discovery in our investigations, both as regards the specific maladies of our patients and the nature and affinities of disease generally, and so aids us in readjusting the conditions of health when these have been deranged in the individual, and in suggesting measures for the protection of the public health. As medical men we have not merely to identify and catalogue the symptoms of disease, but we have to trace them to their antecedents and true causes, and this we can only do by invoking imagination's help, to supply us with speculations and hypotheses, which are not less essential to us in our work than the microscope, test-tube, and clinical thermometer. All true science rests on imaginings, and is, strictly speaking, a body of established truth which imagination has built up. Sensible phenomena are not rightly discerned until illuminated with ultra-sensible light, and our knowledge remains a heap of sequences and coexistences until imagination steps in, and, by combining, adding, subtracting, and arranging, determines how these were brought about and how they stand related to each other. The way in which medical knowledge is attained is identical with that by which reasonable knowledge is acquired in common life. ..... "Without imagination," says Tindall, "Newton would never have invented fluxions, or Davy have decomposed the earths and alkalies." Faraday's discoveries must be ascribed to the amazing fertility of his imagination. Through imagination Harvey beheld the circulation of the blood. Darwin has transformed biology by an hypothesis. Pasteur's passage from the facts of fermentation to the prevention of hydrophobia has been a brilliant flight of speculations, and Lister's advance from Pasteur's earlier experiments to the triumphs of antiseptic surgery has been a chain of admirably conceived hypotheses; and in these, and indeed in all instances of scientific progress, the noteworthy point is that it is imagination which has not only anticipated the conclusion, but given the insight. .....

The cultivation of the imagination, then—and it can be cultivated and disciplined to agility and steadiness of action,—is of high importance to us as medical men; for it can be serviceable in collecting materials, in showing different problems, and, by the analogies it suggests, in guiding us in our life-long search after truth. ..... But it may be objected that the imagination, if sometimes stimulating and restorative in its influence, is often morbid in its tendencies, and that its indulgence is to be guarded against by those who desire to possess well-regulated minds. ..... But the weak vessels wrecked by imagination are really fewer than is commonly supposed. ..... A vulgar error as to the nature of insanity has perhaps conduced to exaggeration as to the dangers of imagination. Visitors to asylums invariably arrive expecting to find growths of morbid invention and belief, wild, tangled, and luxuriant as a tropical forest, and leave much disappointed by the barrenness of the land, for the insane are the least imaginative of beings. At rare intervals a madman is encountered—a Blake or a

Digitized by Google

Swedenborg—whom two intrepid doctors have certified, who dazzles all around him by the meteoric brilliancy of his conceptions; but, as a rule, the lunatic is as dull as a stone..... Idiocy is the absolute negation of imagination, and insanity undermines and destroys or enfeebles it more or less; and, when we try to drive out insanity, the first thing we do is to invoke imagination's aid, for moral treatment consists mainly in appeals to this faculty, and fully acknowledges its hygienic uses. .....

Imagination seems to have a trophic influence on the brain. When it is absent, tardy growth goes on; when it is more or less in abeyance, weakness exists; when it is active, there is vigorous development; and the immediate effects of imagination in causing exhilaration and preventing sleep when it is excessively indulged almost suggest that the states of the cortex which accompany it have some control over metabolic changes in the body. We now know that, besides alkaloids exercising a poisonous effect, which owe their formation to microbes and are called ptomaines, there are others which are produced by the cells of the living organism themselves in breaking down albuminous matter, and which are called leucomaines. Now Bouchard has shown that the alkaloids of the latter kind formed during sleep have a stimulating action, so that, when they accumulate to a certain amount, they excite the nerve centres and cause awakening, while those formed during waking hours have a depressing action and tend to induce sleep. And it is just possible that in the formation of leucomaines of different classes, under varying conditions of the supreme nerve centres, a key may be found to the curious fact that certain emotional moods, after having persisted for a time, tend to induce their opposites—excitement, depression—appetite, disgust; and also to the influence of imagination, when very active, in causing exhilaration and wakefulness. It is just possible that under such circumstances it may arrest the formation of those leucomaines, usually manufactured during waking hours, which are depressing and lead up to sleep, or so modify decomposition that other leucomaines of a stimulating character are produced. There can be no question that, in insanity, certain states of the highest nerve centres are accompanied by rapid disintegration of the tissues and emaciation, while in other states of these centres metabolism is reduced to a minimum, so that prolonged starvation may be sustained with comparatively little wasting. But it is only an inordinate indulgence of the imagination that produces excitement and interferes with natural slumber; its reasonable and regulated use causing only a certain buoyancy of spirits with which a sense of soothing is associated. Imagination, indeed, legitimately used, combines to some extent the pleasurable effects of both morphine and caffeine, without any disagreeable after-consequences, such as headaches, despondency, or confusion of thought. .....

I have referred to the alleged dangers of imagination as a direct morbific influence, and endeavoured to show that these are illusory; and I must say one word as to the alleged evils attending it, which make it a demoralising agent, and therefore a harbinger of disease, for whatever demoralises tends to upset the equilibrium of the nervous system. Like every good gift, imagination may be prostituted and abused; and, in the history of art, literature, and the drama, abundant pooof may be found that it has been made to pander to vice and folly. But, when this has been the case, it is not so much the imagination that has been at fault as a certain pestiferous element that has been infused into it. We do not blame the atmosphere for the impurities with which it is loaded in our large cities, and so we must not charge to the imagination the degrading and licentious suggestions of which it has sometimes been made the vehicle. .....

In prisons and reformatories there are, perhaps, a few waifs landed there by impulses engendered of blood-curdling tales or hair-stirring melodrama. Every asylum medical officer has seen in the wards under his care more or less distorted reflections of incidents that have vividly occupied the public mind, and in the epidemics of the middle ages we have depicted on the large scale the effects of dominant and startling ideas on populations made unstable by poverty and despair, or religious fanaticism. But in all such cases it is a deficiency rather than a superabundance, immaturity rather than ripeness, of imagination that is responsible for the evils observed. It is the ignorant and neglected boy, keen perhaps with that superficial sharpness that is really a kind of imbecility, but with a narrow intellectual horizon that is lured into wickedness by the "penny dreadfuls"; and the silly and dissipated youths of better social position who go to ruin can rarely trace their downfall to poetry or fiction. Sheer weakness and vacuity or instability of temperament are the soils most congenial to vicious and atrocious ideas. A highly and widely cultivated imagination seems to increase physiological resistance to morbid and profligate suggestions, and also to pathogenic germs, for in plague and pestilence those are most likely to escape who have varied mental resources. ..... The preservation of our juvenile literature from any taint is of paramount consequence, for impressions made on the imagination while brain development is actually going on are not only indelible, but highly influential. Burns and Scott both asserted that they had their bias given to them by the legends of an old woman; and the battle of the sects over education clearly shows what importance is attached to the momentum imparted to the brain and mind during their developmental epochs. ..... Fletcher of Saltoun said that, if he might write the ballads of a nation, he cared not who made its laws, and vast power for good or evil centres today in those who are preparing our school books. .....

That the craving for works of fiction is not only great but growing may be deduced from the figures given from time to time in that useful periodical, the *Publishers' Circular*, showing the number of books of different descriptions published annually, and of new editions issued. Now a table which I have had constructed shows that, whereas in the six years from 1877 to 1882 there were 2632 new novels published, in the six years from 1883 to 1888 there were 3655; the increase, subject to some fluctuations, having been markedly progressive, from 446 new novels in 1877 to 926 in 1888. As the number of works of any class published is a fair indication of the demand for books of that class, it is clear that the consumption of light literature is largely upon the increase. ..... The vast extension of the habit of novel reading amongst us is also demonstrated by an observation of journalistic literature. Newspapers that at one time confined themselves to news, political commentaries, and criticism, now form syndicates to supply their readers with a modicum of fiction. ..... And that the demand for cheap fiction will go on growing can scarcely be doubted. ..... To us as medical men it is interesting to remark that this appetite is most urgent in spring, when nervous erithism exists, and "a young man's fancy lightly turns to thoughts of love," and is least pressing in autumn, when the nervous system is comparatively quiescent. In the Birmingham lending libraries the issue of novels reaches its maximum in March (32,796 were issued in that month last year), and touches its minimum in August (27,140 were issued in that month in 1888—a difference of 5650 in favour of March).

And now, gentlemen, having trespassed as far as I dare on your patience, I must close without having even mentioned several topics in connexion with the hygienic use of the imagination which I had proposed to bring under your notice in some detail. Matthew Arnold said that two-thirds of life are conduct, and it may be truly alleged that three-fourths of thought are imagination. It is not merely the child who builds castles in the air. Each of us—the most matter-of-fact as well as the most romantic—has "cloud-capped palaces and gorgeous towers" known to himself alone, to which in hours of solitude and reverie or sadness and chagrin he retires with ever-renewed wonder and refreshment. And the great faculty that out of thin air constructs these cities of refuge for us, and enables us in a sense to shape our own environment—that is, the handmaid of science, the giver of insight, the harmoniser of discords,—must always receive primary consideration in a study of mental hygiene.

IRISH MEDICAL SCHOOLS AND GRADUATES' ASSOCIATION.—The summer general meeting of this Association took place at the Philosophical Hall, in Leeds, on Wednesday, Aug. 14th, 1889, the President, Dr. Fegan of Blackheath, being in the chair. The following resolutions were carried unanimously:—(1) "That the Council be authorised to form branches of the Association in the United Kingdom." (2) "That the recommendation of the Council be adopted in reference to the arrangement with the *Medical Press*, by which that journal is to be constituted the official organ of the Association." A vote of thanks to the reception committee of the British Medical Association was then passed.

ON THE

PROGNOSIS OF CASES OF ALBUMINURIA, WITH SPECIAL REFERENCE TO LIFE INSURANCE.[1]

BY F. W. PAVY, M.D., LL.D., F.R.S.

THE title of this communication is not my own framing: it was handed to me with the request that I would introduce the subject for discussion by the members of the Association at the present meeting. It stands as evidence of a new departure, the traditional notion being that the presence of albumen in the urine should be regarded without further question as excluding the case from fitness for acceptance by life insurance companies. Reference to works on the principles of guidance for the medical selection of lives for insurance gives in unequivocal terms albuminous urine as a ground for rejection. In former times, however, the urine was not subjected to analysis as a part of the examination of a candidate for insurance in the frequent manner it is now. Brinton, writing in 1856, says with respect to the urinary apparatus: "Careful inquiry will often give us so healthy a history of its function as to allow us to dispense with all further examination, not only of the organs themselves, but even of their secretion. It is only where gout, scarlatina, dropsy, or some other disease or appearance of a like suspicious character, specially directs our research towards these structures that we need alarm or annoy our subject of examination by insisting on any further inquiry." Later on, Sir E. Sieveking in 1882 contended that as no medical man reports on a case for life assurance without examining the thorax, so no report for life insurance ought to be considered complete without a definite statement as to the condition of the urine after examination by the physician, and it is scarcely necessary, he says, to insist upon the necessity of rejection if albumen is found and is persistently present. Under the most frequent examination of the urine that has been practised as a matter of routine in connexion with life assurance, combined with the systematic examination that is frequently adopted as a preliminary to selection for employment in the public services, and the common procedure of now including the examination of the urine in the clinical investigations of a case, whether the symptoms suggest the requirement or not, the knowledge has been acquired that albumen is often found where there is nothing in the state of health to lead to a suspicion of its existence. Thus, through the information that has been gained as a result of the increased observation occurring, an advance has been made sufficient to give the question before the meeting the position of being an appropriate one for discussion, and the gathered experience of the profession cannot fail to be of service in helping to a right settlement of the matter.

Put plainly, the points upon which discussion is invited are: Is it to be considered or not that there are cases of albuminuria which admit of being regarded as eligible for life insurance; and, if so, how are these cases to be distinguished with the requisite confidence from those which are to be looked upon as of a serious nature? The question lies between albuminuria as a functional aberration, which is now admitted to exist, and albuminuria associated with structural disease.

Albuminuria sometimes occurs as a transient phenomenon. Certain conditions of a passing nature are recognised as sometimes productive of albuminuria which disappears with the removal of the condition. If the condition is a morbid one, the albuminuria partakes of the significance of the state that has given rise to it, and the consideration consequently becomes merged into that of the exciting cause, upon the degree of importance of which the prospect to be looked for will depend. There are other conditions in themselves not to be spoken of as morbid, but constituting only ordinary conditions of life which from the evidence of recorded observation may prove productive of albuminuria. An unusual susceptibility to influence may exist, or the condition may be carried beyond the ordinary degree of tolerating power. Forced exercise is mentioned as one condition. In the case of Weston, the great American pedestrian, the production of an albuminous state of the urine upon one occasion under my own observation occurred. It was with his first pedestrian feat in this country, in which he undertook to walk 115 miles in 24 consecutive hours. The state of the atmosphere was against him and he was much distressed by his performance. The urine passed an hour after the finish was albuminous, and contained hyaline and granular casts of tubules, unaccompanied with blood-corpuscles; twelve hours later it was found to have resumed its normal condition. Severe mental strain, as with candidates at examination, is enumerated as another source of temporary albuminuria; immersion of the body in cold water, another. Dr. Barnes says, "When physician to the *Dreadnought* Hospital I saw several cases of transient albuminuria from sudden immersion in cold water." Further, under certain circumstances the ingestion of food may constitute a determining agency. But transient albuminuria need not detain us. It is sufficient to find that the case is only of a transient nature, and, all other circumstances being favourable, it may be disposed of by regarding the prospects as of an ordinary character—at least, such is the view I should myself take. It is where the albuminuria is not of this transient kind that we encounter a more difficult question to deal with, and my own experience would suggest that it will be convenient to group the cases under three heads. It appears to me that discussion will be facilitated and the matter made clearer by adopting such a course. The three groups are—(1) cases in which traces only of albumen are observed, (2) cases in which a notable amount of albumen exists and is always present, and (3) cases in which a notable amount of albumen is found at one period of the twenty-four hours and none at another, or, in other words, cases which possess a cyclic character.

Before speaking of these groups, it must be stated that in every case, as a first consideration, there must be an absence of all the elements, apart from the presence of albumen, of Bright's disease to justify the question of a favourable view being entertained. The albuminuria must constitute the only factor present to admit of the case being regarded as an open one for consideration. It is necessarily understood that the mode of testing adopted is such as to afford an infallible indication to start upon. A careful survey of all the collateral circumstances is therefore called for, and the following are the points to which attention requires to be given:—Whether there is anything in the family or personal history to be suggestive of the existence of renal disease. It is known that Bright's disease occasionally runs in families. The family of a former peer, bearing a title which has now become extinct, has furnished a striking instance of this. Is there a history of antecedent nephritis, gout, lead poisoning, or conditions that would lead to lardaceous disease? Is the age such as to favour the presumption of organic disease? Whilst simple functional derangements are common in early life, structural alteration becomes more common as a source of deviations from the ordinary state in proportion as age advances. Has there been the slightest evidence of œdema, and is there any unnatural pallor? The question of persistent headache, vertigo, and any kind of fit must be inquired into. Is there impaired or disordered vision? If so, by ophthalmoscopic examination it must be ascertained whether the changes in the retina and optic disc belonging to Bright's disease are discernible. Does the examination of the cardio-vascular system reveal by such signs as hardness of pulse, thickened artery, undue cardiac impulse, accentuation of the aortic second sound, and reduplication of the first sound at the apex, the existence of high arterial tension? Has there been anything of the nature of albuminuric dyspnœa or palpitation? A frequent feature of renal disease is anorexia, amounting, it may be, to an actual aversion to food, especially meat; and there may be with it nausea, vomiting, and a disposition to diarrhœa. Another feature is a disposition to inflammation of the serous membranes, but should these conditions exist, the case is scarcely likely to allow a doubt to prevail as to the manner in which it should be dealt with in relation to life insurance. The state of the urine, beyond the presence of albumen, will require attention, An occasional large quantity with low specific gravity is not a matter of import, the permissible inference being that a nerve or some other temporary state has given rise to it. As the habitual occurrence, however, it may possess great significance, and will suffice

[1] Read Aug. 14th at the Section in Medicine of the British Medical Association meeting at Leeds.

Digitized by Google

to excite suspicion of grave disease. An examination microscopically will suggest itself as absolutely indispensable. No opinion, unless other circumstances are sufficient by themselves to lead to an adverse one, should be given without it. Blood-corpuscles will prompt delay and further inquiry. Casts of renal tubules may be spoken of as standing prohibitory; but the absence, on the other hand, of casts does not imply the non-existence of renal disease. Our task would be much lightened if it did. Experience, indeed, is not very rarely supplying instances where the diagnosis of Bright's disease is permitted, and no casts are at the time to be found in the urine. It must not be omitted to be borne in mind that casts are liable exceptionally to be come across derived from the seminal tubules. They closely resemble renal casts, with a very transparent character. They may be found accompanied or unaccompanied by spermatozoa. Recently in a case where advice was sought upon the ground of spermatic trouble I observed them in several specimens of urine passed at distant periods. There was nothing besides to lead to the suspicion of renal disease; but had there been, they might easily have been taken as affording supporting evidence. In another case there actually had been recurring attacks of nephritis, associated with tonsillitis, put down to the effects of taking cold. The case was therefore a complicated one, but, at the time of observation the urine was free from albumen, and the single specimen in which the casts were found also contained spermatozoa. Such are the points that require to be looked to as a collateral proceeding in framing a conclusion respecting the prospects in a case where albumen has been found in the urine; and attention to them may alone suffice to establish a diagnosis of Bright's disease, where, as may rarely happen, the urine may be observed on testing to give no reaction of albumen.

The first of the enumerated groups is that in which traces only of albumen are present. My own experience leads me to say that it is not to be regarded as a specially remarkable circumstance to find urine containing traces of albumen without the case being such as to justify the conclusion that anything of the nature of renal disease exists. It will be understood that what is comprised under the head of traces of albumen is from the indication afforded by the employment of a delicate mode of testing, but one, nevertheless, from which the information given is to be regarded as free from fallacy which some of the tests are open to. With traces of albumen thus found, and with everything else bearing upon the point to be pronounced satisfactory, after a full and careful investigation of the case, I should not consider the prospects invalidated. The granular kidney is the form of renal disease which is especially associated with small amounts of albumen, and what calls therefore for most consideration in the investigation of the collateral aspects of the case is attention to the main coincident conditions belonging to this affection—viz., increased quantity of urine, low specific gravity, and morbid changes in the cardio-vascular system.

The second group of cases is that in which a notable amount of albumen exists and is always present. Instances are sometimes come across of the description named where no history of nephritis can be elicited, no casts of tubules discovered, and none of the general symptoms of Bright's disease recognised. I am not prepared to state that a definite opinion can be given about the future in these cases. I have reason to believe there are some which run on without any serious results arising, but I do not consider that medical knowledge is at present in a position to enable us to differentiate these cases from those which may become developed into well-marked Bright's disease. It is not sufficient that there is an absence of casts of tubules and cardio-vascular changes, for frequently in established Bright's disease our examination fails to disclose the presence of casts; and it is not by any means always that we come across evidence of a positive nature from the heart and arteries, notwithstanding there may be sufficient upon other grounds to diagnose the existence of the disease. It would be only in a case that had been under distinct observation for a considerable time without anything wrong becoming developed that I would venture to look favourably upon the prospects, and even then I should consider that a decidedly more than ordinary risk existed. Without saying more, I submit these cases for the opinion of others to be expressed upon them.

The third group comprises cases with a notable amount of albumen appearing and disappearing in such a manner as to give the case a cyclic character. Of these cases I have personally had a somewhat extensive experience, and since grouping and describing them under the head of "cyclic albuminuria" they have been freely and widely discussed in the profession. They are admittedly cases of functional albuminuria, but also something more—namely, functional albuminuria, with a special, sharply defined, and readily noticeable character, which groups them together into an easily recognisable class standing in a distinct position by themselves. Functional albuminuria is the "generic" and cyclic albuminuria a "specific" group contained within it. The distinguishing character belonging to the case is that, without evidence from other sources of the existence or pre-existence of renal disease, albumen under the ordinary course of daily life is at one period of the day present and at another absent, and that this recurs day after day in exactly the same order. At the period of rising in the morning there is no albumen to be discovered. In an hour or two's time albumen shows itself, increases in quantity for awhile, and then, as the day advances, declines and becomes usually entirely lost before bed-time is reached. Remaining absent during the night, it returns after rising the next day, and subsequently follows the same order that had been previously observed. To call the case cyclic is simply to express an outwardly observable feature belonging to it, and the condition may run on with its repeated diurnal variation not only for weeks or months, but also, it can be said, for years, without anything further becoming noticeable. I have committed myself to a definite opinion with regard to the prospects in these cases, and the opinion I expressed in 1885 is sustained by the experience derived from the extension of time up to the present date and by the additional cases I have seen. It is now about ten years that my attention has been fixed upon the point and that I have made a close study of the subject. Expressing myself upon this foundation, I feel it warrantable to state that with a sufficiently full and careful inquiry it may be ascertained whether the case falls or not in the cyclic functional group, and that, if it does so, a favourable opinion of the future may be given. Speaking with reference to life insurance, the opinion to be given is founded upon the same basis as that which guides to an ordinary medical prognosis. In the latter case, however, it may be allowable to incline more to optimism than in the former, where there is not the outside pecuniary interest placed at stake upon the strength of our opinion, as there is when the question of life insurance is involved. The condition existing is not the ordinary one. It may be taken as standing in the position of a border-line, with a serious outlook on the one side and a favourable one on the other; and everything depends upon whether, by the light of other considerations, it is viewed rightly or not. Under these circumstances, if insurance companies should decide to admit these cases as eligible for acceptance, it is not unreasonable that an additional premium should be demanded to meet the possible contingencies, whether from diagnosis or otherwise, that may arise.

Chemistry has shown that several modifications of albumen exist, and the number has been an increasing one with the recent advances made by research. The usual form met with in renal disease is serum-albumen, which is precipitable by mineral and not by the organic acids. It is certainly the exception and not the rule in cases of structural disease of the kidneys to find that anything in the shape of proteid matter is thrown down by the organic acids. In cyclic albuminuria, on the other hand, my experience leads me to say that it is the rule instead of the exception for the addition of an organic acid to be followed by the production of a precipitate. What is usually observed in this class of case is that two kinds of albuminous matter are present: one which, like alkali-albumen and mucin, is precipitated by an organic acid, and the other which corresponds with serum-albumen. I submit the question of the chemical nature of the urinary albumens as far as it bears on diagnosis for further elucidation by those taking part in the meeting.

The remark I have in conclusion to make is that the safety of an opinion will depend upon the completeness and carefulness with which the investigation of a case is made. I designedly use the word "investigation," for something more than the kind of examination ordinarily made for life insurance purposes is needed in the class of case that has been referred to.

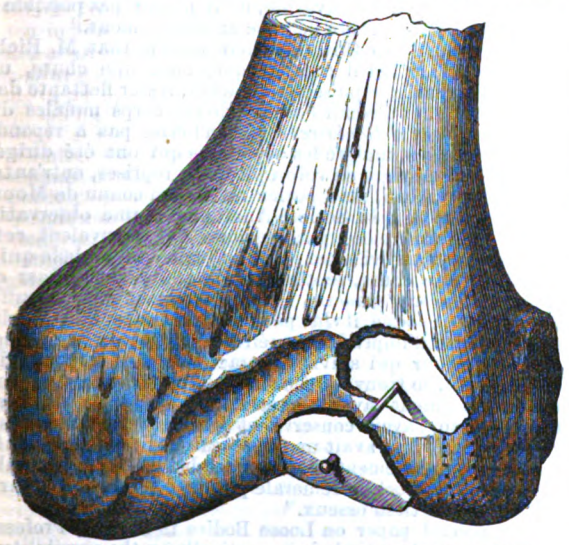
A CASE OF



LOOSE BODY IN THE KNEE-JOINT, FORMED BY THE DETACHMENT OF A PIECE OF THE ARTICULAR CARTILAGE BY AN INJURY.

REMOVAL; RECOVERY.

BY W. H. A. JACOBSON, M.CH. OXON.,
ASSISTANT SURGEON TO GUY'S HOSPITAL.

J. K——, aged thirty-two, while doing his work as a railway porter was moving a cask weighing 2cwt., when it slipped, and in falling struck him violently upon the inner side of the right knee, which was bent at the time. Shortly after he noticed a large bruise, and the joint gradually swelled and became so painful that about a month later the patient was obliged to desist from any attempt to get about. He then came under treatment at Guy's Hospital. The joint was in a condition of chronic effusion, with all the signs of a considerable collection of fluid. No heat or redness; marked tenderness on inner side. No history of any sudden locking of the joint. The fluid was gradually absorbed by treatment, but the joint recovered no strength, and was crippled and painful as soon as the patient attempted to use it. I had repeatedly examined for a loose body but without result, when one day, by the merest chance, I detected, on the inner side of the joint, the smooth darting movement of a loose cartilage. This slipped away as quickly as it came.

The patient was admitted on March 17th, 1886, and operated on upon the 19th. The "loose body" could be

Loose body found after a recent injury within the knee-joint (Nélaton). The dotted lines show the condition of the inner condyle in my case as judged by touch.

detected on two or three occasions, sometimes on the inner, sometimes on the outer side of the joint. On the day of the operation, as often happens, it could be neither seen nor felt. An incision, two inches long, was made along the inner side of the patella, going down to the capsule, every bleeding point being carefully compressed with a Spencer Wells' forceps. The inner side of the joint was chosen, as this had been the site of injury and was still distinctly tender. The capsule being opened, the index finger, when introduced, came at once upon a distinctly depressed roughened patch, deficient in cartilage, situated upon the anterior and encroaching slightly upon the inferior aspect of the convexity of the internal condyle. (See Engraving.) This roughened patch contrasted very sharply with the surrounding smooth, cartilage-covered articular surface. Attached to it at one spot was a small, irregular, slightly movable body. This was readily detached with the finger nail, and when extracted was found to be about the shape of a grain of wheat, and to show altered bone and articular cartilage. As this was clearly not the "loose body" which had been felt, which was certainly detached and very mobile, further search was made, this for some time revealing nothing. After a while the tip of the second finger could just detect a much larger loose body at the extreme upper and outer angle of the synovial sac. After several attempts this was hooked down and removed. The causes of difficulty here were the close proximity of the patella to the condyles, and consequently little room for manipulation, and the position of this second loose cartilage high up in the extreme upper and outer limit of the infra-patellar pouch. As the interior of the joint had been a good deal handled, a small drainage-tube was inserted through the wound, and brought out by a counter-puncture on the inner side of the popliteal space. The wound in the capsule was closely united with chromic gut sutures, and three silk ones inserted superficially. Sal-alembroth dressings were then applied, but before these were secured the leg and foot were evenly bandaged up to the knee. Carbolised sponges were packed on either side of the joint, to make pressure, and thus prevent any effusion of fluid. The first and smaller body is irregular in shape, somewhat resembling a gigantic oat. One aspect, the attached, is roughened, the other smooth, roughly convex, and covered with altered articular cartilage. The second and larger body evidently corresponds to the part of the rim of the internal condyle, which was missing, and represented by the rough patch above mentioned. It was covered on one aspect with smooth, yellowish-white articular cartilage; the other, the posterior aspect, shows a bony surface, dotted with minute pits.

March 20th: Condition very satisfactory. No oozing. Pain very slight.—21st: Temperature 100°; pulse 88, quiet.—23rd: Dressings changed on this the fourth day, that the drainage-tube might be removed. Sponge pressure re-applied. A patch of discharge, about the size of a shilling, had come into, but not through, the dressings. The highest temperature since the operation has been 100·8°.—30th: Second dressing. Wound quite healed save at site of drainage-tube. All sutures removed. Wound to be dressed with ointment of boracic acid and iodoform.—April 7th: Went out to-day in one of Mr. Croft's splints, within three weeks of the operation. He continued to attend as an out-patient, and had a Martin's bandage substituted for his splint. When he was last seen in May the joint was still somewhat stiff, but yielding to active flexion.

Professor Humphry[1] assigns at some length his reasons for being sceptical as to the origin of "loose bodies" in joints by the detachment of portions of the articular cartilage. These are: (1) "It must be a very extraordinary and violent accident that would break off into the knee-joint a piece of the articular cartilage, with or without bone, of the femur or tibia. One can scarcely imagine the occurrence of such an accident, nor conceive how it could take place. Even a smart blow from a hammer would hardly produce it, and in any event such an accident would be attended with severe shock and contusion of soft parts, ecchymosis, and immediately consecutive pain, inflammation, and other trouble, which the sufferer would not quickly recover from, and would not easily forget, but which we do not find forming part of the history in cases of loose bodies in joints." In answer to Professor Humphry's objections, I will call attention, one by one, to certain points in the case which I have published, and which seem to me reasonably conclusive that it was a case of "loose cartilage" originating in an injury and in that alone.

1. (α) *A very severe injury.*—A cask weighing 2 cwt., slipping from a man's grip, swings round and strikes him full upon the inner side of the bent knee. In my patient and in Mr. Teale's,[2] in which a piece of articular cartilage was injured by an accident, and slowly exfoliated during twelve months, becoming loose at the end of the time, the violence is strikingly similar. Mr. Teale's patient, aged thirty-seven, "accidentally let a cask, which he was lowering into a cellar, slip against the right knee." (β) *The position of the limb.*—This was distinctly stated to have been flexed, a position which would tend to expose to violence, by opening out the joint, the articular cartilage on the inner condyle to any violence from the inner side. (γ) *Severe bruising* followed, pointing to the violence received. Thus the knee quickly swelled up, and the patient was obliged to give up his work. In Mr. Teale's case, "severe pain in the joint

Digitized by Google

followed, and he was unable to work for three months, after which time he followed his employment as usual for nearly twelve months, until a few days ago, when he became suddenly lame, and was unable to bear his weight on the right leg." During this time the cartilage was exfoliating.[3] While I admit that the above is not the history which one usually gets from a patient with a "loose cartilage," it is exactly that which one would expect in a case dating to injury.

2. Professor Humphry's second objection is: "Such a detached or semi-detached fragment could scarcely assume the even surfaced, spherical, or circular, flattened form of a loose cartilage." I would reply that, with the smooth and even surface presented by its articular cartilage, the larger of the two bodies removed in my case was an excellent example of a "loose cartilage," the above characters being also well shown in its rapid furtive movements and the facility with which it got out of reach.

3. Professor Humphry's third reason for being sceptical as to the traumatic origin of these loose bodies is as follows: "We have a ready and sufficient explanation of the formation of loose bodies in the growths into the joint of tufts or processes of synovial membrane which may assume various forms, which, naturally containing cartilage cells, may become the seat of cartilage growth and ossification of the cartilage, which become pendulous as they increase, and by rupture of the pedicle become loose in the joint; and we frequently see the various stages of this process in the same joint. We need not, therefore, search for other and highly improbable modes of origin. I may observe that the ossification which takes place in them accords with the ordinary process of ossification in cartilage, and a section of one of them does not correspond with that of articular cartilage and bone. This process is quite sufficient to explain the origin of the single as well as of the multiple loose bodies, which latter are common in rheumatic arthritis; and we not unfrequently meet with instances in young persons where a solitary loose body, not having yet broken loose from its moorings, retains its attachment to the synovial membrane."

To the above I would reply: 1. That the fact that these loose bodies originate far more frequently as suggested by Professor Humphry does not of necessity exclude another though less common mode of origin. Rare as it is to find "loose bodies" in a joint originating in an injury, such cases as M. Richet's and mine[4] show that such an origin is a *vera causa*, directly or indirectly, by causing slow exfoliation. The rareness of this origin makes it important not to lose sight of it in cases of obstinate synovitis dating to an injury. 2. The condition of the interior of the joint afforded evidence, both positive and negative, in favour of a traumatic origin of the loose cartilage. Thus, in the first place, there was an entire absence of that alteration in the synovial membrane which one would have expected to meet with, if the loose bodies had originated in a synovial fringe gradually becoming polypoid and detached. Thus there was no evidence of enlarged and toughened synovial processes, no fibro-cartilaginous nodules; the inner surface of the joint was everywhere, save for one spot, smooth and normal. This spot, which, rough and bare, at once arrested the exploring finger, was situated on the inner and inferior part of the articular surface of the internal condyle. It was about three-quarters of an inch long, and had still attached to it the smaller of the two bodies removed. This, which was almost loose, was a small piece of the articular cartilage and bone of which the vitality had been damaged but not completely destroyed at the time of the injury. When it had been detached with the finger-nail, the roughened surface with which it was in contact corresponded closely, in shape, size, and feeling as of exposed bone, to the base of the larger loose body, which was also rough and bossy. Furthermore, this roughened patch on the inner condyle corresponded precisely to that pointed out by the patient as having been struck by the cask. 3. The appearance and structure of the loose bodies removed. These seem to me to complete the evidence that the above bodies were traumatic in origin. (*a*) The appearance: This is entirely against the view that these loose bodies had developed as cartilage in a synovial tuft, gradually increasing and becoming pendulous. It is equally opposed to any osteo-arthritic origin; for there is no trace of synovial tissue attached to either of the bodies, and there is nothing approaching to a pedicle. (*β*) The structure: It has already been stated that to the unaided eye this showed articular cartilage and subarticular lamella of bone. A microscopical section showed a dim granular matrix, with groups of cells scattered in it. Below this was a distinct layer of true bone, with well-formed and regularly arranged Haversian canals &c. Now, the above is not the structure of the loose cartilage, which has formed in a synovial tuft or in an osteophyte. It can scarcely be the structure of any other loose body save one dating to an injury. In all other kinds there is much less evidence of definitely organised tissues. Any cartilage present in them is usually highly fibrous, not hyaline, as in the articular variety, and any cells present are not grouped. Calcareous matter often takes the place of true bone, and where this last tissue does appear to be present, it usually lacks the regular arrangement of Haversian systems, lacunæ, and bone corpuscles.

M. Nélaton[5] thus alludes to loose bodies originating in injuries. One of these is represented in the woodcut.

"Dans d'autres observations, le corps mobile présentait une surface rougeuse, hérissée d'aspérités, et de structure osseuse, tandis que l'autre était bien polie et de nature cartilagineuse. Tel était celui qui fut extrait du genou d'un homme opéré par Velpeau, et dont M. Richet a publié l'observation. Ce corps présentait ceci de curieux, qu'étant osseux dans presque toute son épaisseur, il n'était recouvert de cartilage que sur l'une de ses faces. Il ressemblait tout à fait, lorsqu'il fut extrait, à une portion détachée de l'extrémité articulaire du fémur, car la face cartilagineuse était convexe. L'autopsie prouva que telle était bien son origine: en effet, on rencontra sur l'extrémité inférieure du fémur un perte de substance profonde, de forme parfaitement semblable à celle que présentait le corps mobile précédemment retiré, lequel, une fois replacé, s'adaptait tellement bien à l'excavation, qu'il n'était pas possible de douter qu'il n'en eût été détaché antérieurement."

It is probably to this case, here shown, that M. Richet thus refers[6]: "Est-il possible que, dans une chute, une portion du cartilage puisse se détacher, rester flottante dans l'articulation, et devenir l'origine de ces corps mobiles dits *corps étrangers articulaires?* Je n'hésite pas à répondre par l'affirmative, malgré les objections qui ont été dirigées contre cette manière de voir à plusieurs reprises, entr'autres par Parise. Ainsi, sans parler du fait si connu de Monro, j'ai lu, en 1843, à la Société Anatomique, une observation et présenté une pièce pathologique qui prouvaient cette origine jusqu'à l'évidence. Il s'agissait d'un malade qui, à la suite d'une chute, sentit en relevant *quelque chose* qui roulait dans son genou. Comme il continuait à souffrir depuis cette époque, il vint pour se faire traiter à la Charité, où, par suite d'imprudences réitérées, il succomba le vingt-cinquième jour qui suivit l'extraction de ce corps mobile. A l'autopsie, je trouvais sous le condyle interne du fémur un emplacement ayant exactement la forme du corps étranger que j'avais conservé, et dans lequel nous pûmes le replacer; ce corps avait une face cartilagineuse et l'autre osseuse, et précisément la perte de substance qu'avait subie en ce point la trochlée fémorale portait toute à la fois sur le cartilage et le tissu osseux."

In a second paper on Loose Bodies in Joints,[7] Professor Humphry speaks a little less sceptically on the possibility of the origin of these bodies in the detachment of portions of articular cartilage and bone by accident. "With regard to the former of these modes of detachment—namely, by accident—I am not aware that any reliable instance has yet been adduced of the formation of a loose body by the breaking off of a piece of articular cartilage or bone by a blow; and we can scarcely conceive such an occurrence without greater damage to the joint than appeared to have taken place in any recorded case of loose body in the synovial cavity." Professor Humphry, however, goes on to admit that there are "two instances of the production of loose bodies in the joints by accident—viz., (1) a specimen[8]

[3] In a letter to which I have referred later, Professor Humphry has been good enough to inform me that he has had the above specimen of the elder Mr. Teale examined microscopically, and that he has "found it clearly not to be a knocked-off piece of bone and cartilage."

[4] As will be seen a little later, Professor Humphry is inclined to admit two other cases.

[6] Traité pratique d'Anatomie Médico-Chirurgicale, p. 130.

[7] Brit. Med. Jour., Sept. 19th, 1888.

[8] This specimen is in St. Thomas's Hospital Museum. The description of it will be found in the Path. Soc. Trans., vol. xv., p. 206. It is figured by Mr. Howard Marsh in the Brit. Med. Jour., April, 14th, 1888, p. 787. Mr. Marsh here and elsewhere (Dis. of the Joints., p. 181), gives reasons for believing in the traumatic origin of loose bodies in joints. It will be remembered that Professor Humphry's remarks were first elicited by a case which Mr. Sheild brought before the Medical Society (Brit. Med. Jour., March 3rd, 1888, p. 469). See also a letter by this surgeon, March 31st, 1888, p. 718.

Digitized by Google

of a fragment of cartilage and bone taken by Sir J. Simon from the knee-joint three weeks after a wrench received in falling; and (2) the specimen figured by Mr. Teale,[9] which, with its rough (fractured) bony surface on one side, and articular cartilage on the other, as seen in the bottle, leaves no doubt, I think, that it was, as he concludes, broken off from the articular surface of the patella by the severe wrench which he describes. Possibly it was broken off by a violent wrench against the margin of the femoral condyle, and the St. Thomas's specimen may have been due to the same cause." In a letter in reply to one in which I drew the Professor's attention to my case, he writes: "Your specimen seems to me the most clear instance of a loose body caused directly by a blow."

Finally, I would repeat that the object of this paper is to add one more case to prove that loose bodies in joints do occasionally originate in an injury, and in no way to question Professor Humphry's opinion that the great majority of these bodies are derived from the synovial membrane after the manner which he has described.

Great Cumberland-place, W.

CASES TREATED BY HYPNOTISM AND SUGGESTION.

BY CHARLES LLOYD TUCKEY, M.D., C.M. ABERD.

LAST autumn I had the pleasure of watching for a fortnight the practice of Dr. Liébeault of Nancy, and was much struck by some of the cures I saw him effect by hypnotism and suggestion. Liébeault is the pioneer of the system which has during the last few years been so prominently brought before the profession by Bernheinoq, Charcot, Heidenhain and other eminent foreign physicians. The treatment is conducted at Nancy almost as a matter of routine, and is shorn of all mystery and objectionable surroundings. The power to hypnotise does not seem to belong to one person more than another, and probably any medical man will arrive at a fair amount of dexterity after a little practice. Lethargic and anæmic subjects are perhaps the most encouraging patients to begin with, and boys about the age of puberty seem especially susceptible. Though the majority of people can be influenced by hypnotism, only a small percentage arrive at the more intense stages which involve unconsciousness; and for therapeutic purposes a slight degree of languor or somnolence is sufficient. For example, of over a hundred patients of all ages and in all ranks of societv, I have only completely failed in twenty-three cases; but among the eighty influenced I found only seven who completely lost consciousness and were susceptible to the advanced phenomena described by Charcot as characterising "le grand hypnotisme." The induction of the hypnotic state is of course merely preliminary to the treatment by suggestion, and it appears to act by closing the channels of ordinary thought and directing the attention of the patient exclusively to the point indicated by the operator. The immense power of directed consciousness to influence the organs and functions is so often seen in practice, and has been so well shown by Dr. Hack Tuke and other observers, that we may well credit it with most of the curative effects of the treatment. Faith on the patient's part is not required, but his hostility or mental preoccupation will render futile any attempts to hypnotise him; it is well, therefore, on every ground to act upon the warning given by Professor Beaumis: never to operate without the patient's formal consent, and in the presence of witnesses. The following cases were treated by hypnotic suggestion.

CASE 1. *Insomnia.*—A. T——, electrician, aged thirty-five, had suffered from sleeplessness for three years, as the result of shock after a severe accident. He invariably awoke at 3 A.M. whatever time he went to bed, and was unable to sleep again. He was a man of exceptional mental activity, and want of sleep had induced much nervous depression and dyspepsia.—Feb. 1st: He was hypnotised, and at once fell into a slightly lethargic state (Liébeault's first stage), and the suggestion was made that he would sleep well that night and would not awake at the usual time, but that even if he did awake he would be able to sleep again.—2nd: He awoke at 3 A.M., but almost at once went to sleep again. He was again hypnotised, and told to sleep steadily through the night.—3rd: He awoke about 4 o'clock in consequence of a noise in the street, but soon fell asleep again.—5th: He reported having had two good nights, and the suggestion was repeated. From this time he has remained a good sleeper, getting an average of eight hours' sleep every night, and his general health has greatly improved.

CASE 2. *Chronic diarrhœa.*—General B——, aged seventy-two, came under hypnotic treatment on April 3rd. He had previously been attended by me for chronic diarrhœa, but without much effect, and the malady was generally considered quite incurable. It dated from the time of the Crimean war, and since then he had never passed less than four motions a day, and these were always thin and watery. Any excitement or emotion aggravated the condition, and the day previously to my visit he had been moved twelve times. He is a man of exceedingly nervous type, but enjoys fairly good general health for his age. Hypnotism produced very much the same effect on him as on the preceding patient—a slight lethargy. In this state his abdomen was gently rubbed and the suggestion made that he should in future have but two motions a day, and that they should be properly formed. On April 4th the patient reported three motions during the last twenty-four hours. He was again hypnotised, and the same suggestions were repeated. On the morning of April 5th he passed the first formed motion he had had for over twenty years, and from that time his bowels have continued to act regularly twice a day and the stools have been well formed and natural.

CASE 3. *Paroxysmal sneezing.*—F. H——, thirty-eight, lady's maid, suffered during the summer of 1888 from hay fever, and the fits of sneezing continued into the autumn, so that when I saw her on Oct. 4th she told me that every morning on awaking she was seized with a paroxysm, which lasted about an hour, during which time she sneezed about forty times, and discharged copiously from the eyes. In addition to this, for a few days she had suffered from pain after eating, flatulence, and constipation. She was hypnotised, and at once fell into a profound sleep (Liébeault's sixth stage). Her nose was rubbed, and the suggestion made that she should sneeze no more. The stomach was also rubbed, and the suggestions made for the regulation of the digestive functions. There was no need to repeat the operation, for the paroxysmal sneezing ceased forthwith, and the digestion became easy and painless. There has been no relapse.

CASE 4. *Nocturnal enuresis.*—Alice C——, aged nineteen, a dressmaker, came under treatment on Jan. 15th. She was anæmic, highly nervous, and suffered from dysmenorrhœa. She had always been addicted to wetting the bed, and had never passed more than a few consecutive nights without doing so. The habit prevented her getting employment and had resisted all treatment. The week before seeing me she had come out of hospital, where she had spent a month without benefit. She fell into the third or cataleptic degree of hypnotism, and was told that the habit was to be cured, and that she was to awake at 2 A.M. and leave her bed to void urine. — Jan. 16th: The night had passed without accident. She awoke about 2 A.M., left the bed as directed, and then slept until called in the morning. The treatment was repeated. On the 17th a similar report, but she had wet the bed on the night of the 18th. This was the last time the habit recurred, and she has since awoke spontaneously in the middle of the night and left the bed. The dysmenorrhœa at the same time has almost disappeared, and the general health and mental condition have improved.

CASE 5. *Functional dysmenorrhœa.*—A. T——, aged twenty-one, clerk, came under treatment on Oct. 10th, 1888. She suffered much from painful menstruation, and has done so since the function became established four years previously. The period was always delayed three or four days, and was scanty and light coloured. It lasted about three days, and was attended with excessive backache, languor, and frontal headache. She suffered also from gastralgia, constipation, and flatulence. After treating her for some time on general principles, she was hypnotised on March 15th, immediately after a period, and at once fell into a profound sleep (Liébeault's sixth stage). Suggestions directed to the painless performance of the digestive and menstrual functions were made and were repeated two or three times a week for four weeks. The following period appeared on the twenty-ninth day, and

[9] Brit. Med. Jour., May 26th, 1888, p. 1109.

Digitized by Google

was attended by but little pain or inconvenience. She was told to return in three weeks, and suggestions were then made regarding the next period. This came on twenty-seven days after the last, and continued for four days. It was more abundant and healthy, and perfectly free from pain. Since that time she has continued regular, and there has been no dysmenorrhœa. The digestion soon became painless and natural, and the general health shows great improvement.

CASE 6. *Tabes dorsalis.*—H. F——, aged forty-seven, a gentleman's servant, came under hypnotic treatment on March 9th. His family history was good, and he had never drunk to excess or had syphilis. About five years ago he had what he called blood poisoning, and what appears to have been a severe attack of typhoid fever. He had been severely wounded in the leg in the Franco-German war, but had made a good recovery. About the beginning of 1888 he noticed his sight was failing, and at the same time the skin of parts of the back became numb. His bowels became constipated, and when moved with the help of purgatives the action was attended by so much colicky pain and vomiting as to confine him to bed for twenty-four hours afterwards. He suffered from frequent sharp lightning-light pains in the limbs and from neuralgia in the chest and back. The tongue was coated and dry; he had no appetite, and there was great mental depression. He had lost two stone in weight in twelve months, and presented an emaciated and cachectic appearance. He was unable to walk more than half a mile, and always felt tired. His pupils were contracted and almost insensible to light, and there was nearly complete atrophy of the right optic nerve with partial atrophy of the left. The reflexes were absent, but there was nothing ataxic in his gait. Extensive patches of local anæsthesia occupied almost the whole of the left thorax and the back, and also the nose and upper lip. He was hypnotised, and fell into the third stage. Suggestions were made as to his bowels, digestion, sleep, and pains, the parts at the same time being gently rubbed.—March 10th: Bowels had acted slightly after breakfast (the first natural relief for three months), and with but little pain. He had slept well and felt better. The treatment to be repeated. — 11th: Bowels acted again more freely and quite painlessly. Suggestions repeated. He was hypnotised daily until the end of March, and by that time his general health was found to be greatly improved. He enjoyed his food, hardly ever had any pain, and was able to walk four or five miles without fatigue. His sight, which was rapidly deteriorating previously to the treatment, had remained stationary, and was always somewhat clearer for some hours after each sitting. The patient is still under observation, and though the disease probably progresses, he is, as a rule, fairly comfortable and free from pain.

CASE 7. *Torticollis.*—W. T——, aged thirty-four, consulted me on March 3rd for rheumatism of the muscles of the neck, shoulders, and back. She was subject to rheumatism, and the present attack had appeared suddenly about two weeks before after exposure to wet and cold. She had been unable since that time to dress or undress herself, and the least movement of the head or upper extremities caused pain. The muscles were tender to the touch, but there was no swelling or constitutional disturbance. The patient was advised to try hypnotism, and with some reluctance, for she said she did not believe in it, she consented. In less than a minute she slept profoundly, and in this condition the affected muscles were well rubbed for two or three minutes and the head turned in various positions. Within five minutes of her being hypnotised she was aroused, and asked to move her head and arms freely. This she did without pain, but said there remained a slight stiffness. The stiffness continued until the following morning and then disappeared, and the symptoms did not recur.

CASE 8. *Headache, restlessness, and uterine pain after confinement.*—F. Y——, aged forty-three, was confined of her fifth child on Jan. 20th. She was anæmic, and had had much colicky pain, headache, obstinate constipation, and hæmorrhoids during the last two months of gestation. Delivery was tedious, and there was much hæmorrhage from the relaxed and insufficiently contracted uterus, and the placenta had to be removed as it remained adherent. The patient complained greatly of headache and restlessness after the placenta was removed; the uterus contracted but slowly, and there was much pain, in spite of hot douches and ergot. She knew nothing of hypnotism, and was directed to look at my forefinger, and to compose her mind as much as possible. In a few moments the eyelids began to twitch, and almost immediately she closed the eyes and sank into a profound sleep, which lasted for four hours. She awoke greatly refreshed, and without headache or after pains. The operation was repeated daily, and she made an unusually good recovery.

CASE 9. *Scrivener's palsy* (*partial*).—Alice N——, aged thirty, post-office clerk, came under treatment on Jan. 10th. She had been in post-office employment for fifteen years, and had had a great deal of writing and telegraphing to do. About four years previous to her visit she had begun to feel numbness and loss of power in the right forefinger and thumb after writing a few lines, and this was followed by pain along the front of the forearm, extending to the elbow. This condition gradually became worse, and in 1888 she was for three months under electrical treatment at St. Bartholomew's Hospital, with temporary benefit. She was fairly well nourished and complained of no other symptoms. The grasp of the right hand was considerably weaker than that of the left, and there was some tenderness and soreness on pressure of the flexor muscles in the forearm. But the muscles were not wasted, and there was no hyper-sensitiveness apparent along the course of the nerve trunks. After writing four or five lines she complained of loss of power and numbness in the fingers, and pain in the forearm, and was obliged to give her whole attention to holding the pen and to grasp it tightly. She was hypnotised, and immediately fell into a profound sleep. In this state the muscles were masséed, and the fingers forcibly extended and pulled out. She was told she would be able to write without pain or embarrassment, and that the hand and arm would soon gain power. In a few minutes she was awakened, and told to sit down and write a page of foolscap, and this she did almost without fatigue. The treatment was repeated three times a week for a month, and she then reported herself quite cured. All tenderness and stiffness of the muscles had disappeared, and the grasp of the right hand was at least equal to that of the left. She has since continued well, and is able to write many hours a day without inconvenience.

CASE 10. *Dipsomania.*—L. G——, a gentleman of position, who was intensely anxious to be cured, was under my care during the month of January. His case was a bad one, and for three years had been getting worse. Uncontrollable fits of craving for spirits recurred every two or three weeks, and indulgence for three or four days was followed by intense nervous depression. He was hypnotised twice daily, and, like most of these patients, he was a very susceptible subject. Suggestions were always made that he should look upon spirits and intoxicating liquors generally with dislike, and that he should have no craving or wish for them. Under this treatment his appetite soon became very good, he slept well at night, and recovered his spirits. In four weeks he was able to return to his family, and he writes at intervals, telling me that, in spite of exceptional temptation, he has no inclination to taste alcohol or break his promise to me.

Notes to cases.—1. The treatment of sleeplessness by suggestion is one of the triumphs of the system, and when this symptom occurs in almost any disease it at least can nearly always be removed if the patient is susceptible to hypnotism. 2. The same remarks apply to chronic constipation and diarrhœa and their treatment by suggestion. 3. The success of suggestion in this case seems to point to its use in hay fever—at least, when of a purely neurotic type; and Dr. Van Eeden of Amsterdam tells me he had several successes in treating this malady last summer. 4. The physicians practising hypnotism make a strong point of its success in nocturnal enuresis, and, in fact, consider it specific in functional disturbance of the urinary system. It is of great importance to make the patient promise not to wet the bed. 5. I have here given a case of functional dysmenorrhœa only, yet it is certain that when painful menstruation depends upon a well-defined pathological condition it may often be affected beneficially by suggestion. In one of my cases menstruation was attended by pain in the back, bearing-down ovarian irritation, occipital headache, and giddiness. All these symptoms have disappeared, though the state of uterine subinvolution remains, as shown by the sound passing nearly four inches. 6. This case is interesting, as showing the power of suggestion to relieve pain and other symptoms in organic disease. How great the relief may be is shown by a case reported at

Digitized by Google

great length by Professors Fontain and Sigard of Toulon,[1] where a man in an advanced stage of disseminated sclerosis of the cord was so benefited as to be enabled to leave the hospital. The diagnosis was verified, as the patient returned within a year and died of tuberculosis. An elaborate necropsy revealed very extensive patches of sclerosis and render the improvement in the symptoms a remarkable feature of the case. 7. In rheumatic torticollis, lumbago, and sciatica, hypnotic suggestion acts very satisfactorily, and in many cases of chronic rheumatism great improvement results from the patient employment of hypnotism combined with massage. 8. It appears as if hypnotism will prove a most useful auxiliary in the lying-in room. Several observers relate cases in which women have been painlessly confined under its influence, and it may often be employed to relieve after pains and to procure sleep. The mental condition induced by the combined mental strain and loss of blood render the puerperal woman especially susceptible to hypnotism. 9. In the treatment of writer's cramp brilliant results have been attained by hypnotic treatment, and in my own practice I have found no circumstance more gratifying and convincing than the rapid improvement which follows suggestion. 10. The treatment of dipsomania and the morphia habit by suggestion opens up quite a new field. In the case quoted, as much, if not more, effect followed a month's treatment as is generally expected from a year's esidence in a retreat. The Rev. Arthur Tooth of Croydon tells me that he is getting most gratifying results in his institution for dipsomaniacs from the systematic use of hypnotism.

Green-street, W.

NEW SLIDING SPRING REPOSITOR.

BY ALEXANDER DUKE, F.K.Q.C.P.I.,
EX-ASSISTANT MASTER, ROTUNDA HOSPITAL; GYNÆCOLOGIST, STEEVENS' HOSPITAL, DUBLIN.

PLUGGING the cervical canal in cases of severe hæmorrhage (other than post partum) will be found more effectual and much more comfortable to the patient that the older method of plugging the vagina. The want of a simple means for completely and firmly filling the cervical canal has long been felt, but I think it will be found an easy matter by means of the instrument illustrated. It is simply an improved form of sliding repositor, the difference is that instead of the cannula being pushed forwards on the rod, the latter is made to retreat into the cannula by pressure of the

fingers on the projecting cross bars, and so the cotton plug with which the top of the rod is armed is pushed home into the cervix with ease and celerity. It may be urged that a sponge-tent or sea-tangle would be an easier mode of plugging the cervix, and quite as effectual; but besides the inconvenience of having to place a tampon of some kind in the vagina as well, in order to retain the tangle or tent till swollen enough to retain its hold, we have also the great liability to sepsis, and I certainly prefer being on the safe side. The size of the os being determined by digital examination, a piece of absorbent cotton is to be neatly, *but not too tightly, wound* round the projecting part of the rod (which measures about two inches in length) and thickly enough to fill tightly the cervical canal, or a short piece of round lamp wick can be drawn down on the point of the stylet and used instead if the operator prefers. The cotton plug, or wick, is then to be saturated with some antiseptic styptic; a saturated solution of alum in glycerine, Churchill's tincture of iodine, or turpentine; but I have a strong objection to iron in any form. A large-sized cylindrical speculum is now passed, and the os and cervix syringed through speculum till all clots are removed. The cervix is then to be steadied with the tenaculum or the volsellum, held in the left hand, while the repositor, armed with a plug, is introduced with the right; and on pressure being made on the side bars of the instrument the plug is firmly pushed home into the canal, and the speculum and repositor withdrawn. Thus the whole operation can be done without assistance. If the plug is of the right dimensions (which of course must depend on the judgment and experience of the operator), there need be no cause for anxiety, and the antiseptic and astringent properties of the lotion with which the plug was saturated should keep all sweet till expelled by uterine action, thus differing materially from sponge-tent or sea-tangle, which always gives rise to a certain amount of anxiety in the mind of the practitioner the longer it remains *in utero*.

The repositor will also be found useful (as it has been in its original form by the American gynæcologists) for depositing small pieces of cotton wool soaked in some caustic solution in the cervix in the treatment of chronic endometritis, and the leaving of such in the cervical canal need not give the least anxiety to the doctor, as they are sure to be expelled by uterine action, as indeed any substance lying unattached in either the cavity or neck of the womb is bound to be. Messrs. Arnold and Sons, London, are the makers of the repositor, and the instrument on trial will be found a useful addition to the everyday armamentarium of the gynæcologist.

STATISTICS OF PERINEAL LATERAL AND MEDIAN LITHOTOMY:

BEING OPERATIONS PERFORMED ON MALE INFANTS AND BOYS IN THE WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL FROM 1864 TO 1888.

BY T. VINCENT JACKSON, F.R.C.S. ENG.

A FEW months ago my friend Mr. Reginald Harrison wrote to me with a request that I should supply Professor S. W. Gross, of Philadelphia, with a tabulated statement of all the cases of lateral and median lithotomy performed on infants and boys up to fifteen years of age in the Wolverhampton and Staffordshire General Hospital. Mr. Gough, house surgeon, at some trouble grouped together all these particular cases of operation from the hospital books, and the list was forwarded to Professor Gross; but his lamented death soon afterwards having doubtless prevented its publication, I feel that, as the record is one of practical interest and value, I ought no longer to refrain from making it known.

Cases of Lateral and Median Lithotomy from 1864 to 1888, inclusive.

Age.	No. of cases.	Deaths.	Causes of death.
1 to 5 yrs. incl.	70*	2	(*a*) Aged two years. Death from shock 16 hours after operation; very little hæmorrhage at the time or after operation. Stone weighed 10 gr.; uric acid.
			(*b*) Aged three years. Severe shock after operation; no bleeding. Stone weighed 47 gr.; uric acid.
6 to 10 yrs. ,,	47*	2	(*c*) Aged nine years. Death on the 13th day from subacute peritonitis. Stone weighed 100 gr.; urates combined with phosphate.
			(*d*) Aged seven years. Death 5 days after operation, from exhaustion. Stone weighed 312 gr.
11 to 15 yrs. ,,	13*	1	(*e*) Aged fourteen years. Death 2 days after operation, from secondary hæmorrhage. Stone weighed 130 gr.; oxalate of lime.
15 years	1†	0	—
11 years	1†	0	—
—	132	5	—

* Lateral lithotomy. † Median lithotomy.

The above table indicates that during a period of twenty-four years 132 perineal operations for stone in the bladder of boys, varying in age from one to fifteen years, have been

Digitized by Google

performed in the Wolverhampton and Staffordshire General Hospital, and that 5 of the patients died from causes sequential to the operation, 2 of these between the ages of one and five years, or 1 death in 35 cases, 2 between the ages of six and ten years, or 1 death in 23½ cases; and 1 between the ages of eleven and fifteen years, or 1 death in 13 cases. Of the whole number, the death-rate is 1 in a little over 26 cases, the mortality being between 3 and 4 per cent. The authenticity and correctness of this record are undoubted. In our hospital the house-surgeon acts as the surgical registrar, and the duty devolves upon him of entering in the operation-book every operation performed, with its result; and as this book is inspected and signed at each monthly meeting of the Medical Committee, there is no chance of any error or misstatement being undetected or not corrected. Although to a considerable extent I am responsible for the performance of the majority of the operations, yet it must not be forgotten that the present series is not a personal one, but includes the operations of every member of the surgical staff since the year 1864, and as such it is a remarkable and an almost unique record, and it nearly beats the "barely 5 per cent. of deaths" of Cheselden, who cut 213 patients and lost 10.

I do not think it is desirable to lengthen this short paper by copying the lithotomy tables and the conclusions which are to be drawn from them, which are to be found in various published papers, monographs, text-books, and surgical treatises, as I wish these observations to be considered a contribution to the very important subject of perineal lithotomy in male children and boys, especially as at present the employment of other operative methods of dealing with this particular surgical disease is being strongly recommended to be adopted, as it were, to the effacement of that time-honoured operation for the removal of stone from the male bladder—viz., the great English surgeon's improvement of Frère Jacques' method.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF EXTRA-UTERINE GESTATION FOLLOWED BY RUPTURE; RECOVERY.

By T. N. THOMAS, L.R.C.P., M.R.C.S.

AFTER what appeared in THE LANCET of the 13th ult. on Extra-uterine Gestation, the following brief notes of a case may be of some interest.

M. K——, baker's wife, married in September, 1885. After marriage she only menstruated once before becoming pregnant. She aborted in December following without any assignable cause unless it was due to hard work, as she had to stand at the counter many hours in the day. After the abortion she continued at her work as usual, having a rather clear discharge tinged with blood, off and on, for a long time afterwards. The discharge then stopped and she menstruated normally, once in the beginning of February, 1886. She then came pregnant again and carried the child very well until she had gone eight months, when on Oct. 6th she was confined prematurely. The labour was a very tedious one, and the "waters broke" the day before delivery. She was in labour altogether about two days and one night; and, according to her statement, her then medical attendant tried to apply the forceps to expedite the delivery, but for some reason the instrument slipped, and so the delivery was left to nature. Chloroform was not given, though she wished it. The patient got on well after that, and made a good recovery; but the child was very puny, and never appeared to thrive, and on Dec. 2nd it succumbed, owing, as the mother thinks, to the cold weather which then prevailed. The lochia stopped in about a fortnight, and she menstruated about a month subsequently. After this the catamenia lasted a long time at each period, though she did not lose a large quantity, and usually went a month between. She was last poorly at the end of February, 1887; considered herself pregnant, and did not menstruate in March. On April 21st she consulted her doctor, complaining of "bearing-down pain and weight in the womb," which had been going on since the 16th, and on the 20th there had been just a few drops of blood—only a few spots on the linen. On Saturday night, April 23rd, she was seized with a severe attack of pain in the region of the womb, which lasted about an hour, and then entirely ceased. On the following day she had another similar attack in the same place. This also passed off in about the same time as the other. The slight red discharge had continued from the 20th, and still went on. On Monday, the 25th, the pain returned, and continued until 3 P.M., when the doctor was called in; there was then great pain at the lower part of the abdomen, in the middle, just over the pubes; her pulse was good, and nothing abnormal could be felt on palpating the region complained of. This pain lasted continuously from the 25th to the 27th, when, at about 8 P.M., it became suddenly much more intense; in fact, so much so that her friends thought she was dying, and I was called in and saw her about an hour later. She was then in a state of profound collapse (with extreme pallor, small pulse, cold extremities, &c.), had been sick, and had vomited twice. On palpating the abdomen, it was found to be too tender to make out anything definite, or even perform a satisfactory examination. The usual restoratives were administered, to tide her over the collapse, and she was seen again next day, when a tumour was discovered above the pubes, extending from a point just to the left of the middle line right across the iliac region of the right side. The pain abated, and the tenderness diminished daily until April 30th, when she passed a decidua of considerable thickness, which formed a complete cast of the interior of the uterus. Up to this time the slight—very slight—discharge continued, but after passing the decidua it entirely ceased. On May 13th a very slight discharge appeared again, continued for three days, and then stopped completely. After this the hæmatocele disappeared very rapidly, and the patient made a good and uninterrupted recovery.

Leicester.

POISONING BY SICHERHEIT (A NEW EXPLOSIVE).

By JOHN STOKES, M.B., B.S., M.R.C.S.

SICHERHEIT ("security") is a new explosive manufactured by the Flameless Explosive Company, and is used for blasting in confined spaces and in mines. The chief component is dinitro-benzene, probably. The details of its manufacture are as follows. (These particulars were given me by the patient whose case is described below.) The "dinitro" is placed in a pan heated by means of a steam jacket until liquefied; then to this is added a quantity of a white crystalline substance called "oxalate" in the works, and sometimes there is also added another white crystalline substance called by the men "potash" (what these are I cannot discover); the whole mass is then mixed mechanically by means of stirrers, during which process a large amount of bluish smoke is given off. After complete mixture the pan is covered with a lid, and the whole mass is heated for twenty minutes, and then allowed to cool down to the consistency of dough, when it is scraped out by means of brass knives. During this process blue fumes are given off largely; these fumes smell strongly of almonds. The substance is then ground down into a fine powder by machinery, and is sieved by the men; during this work large quantities of the material are inhaled by the men, causing great sneezing. The powder is then packed into suitable cases for blasting purposes. It will be noticed that the occasions in which the poisonous materials are taken into the system are (1) when the substance is being heated, (2) when it is being scraped out of the pan, and (3) when it is being sieved.

Details of the case.—On July 30th, 1889, I was called at night to see G. R——, aged twenty-three years. He was sitting on a chair, with his head thrown back. His face, lips, finger-tips, and nails were blue, and his face had a pinched, anxious look. Pulse weak, rather irregular, 90 per minute; breathing weak and hurried, 30 per minute; temperature normal. He was very nervous and trembling; he had just fainted, and had been very sick. The patient informed me that a week previously (July 22nd) he had started working at the Sicherheit manufactory at Denaby. After the first day's work he noticed that his face and hands were blue,

Digitized by Google

his appetite was gone, and that on exertion he became short of breath, which symptoms had increased up to the time I saw him. After working two or three days, he found that he had great difficulty in passing his urine, and that when he did so the urine was scanty, very dark-coloured, and smelt strongly of almonds. His bowels were also constipated. During the week he had exacerbations of these symptoms shortly after mixing or sieving the explosive. I administered stimulants, and had the man put into a warm bed. The next morning the patient was decidedly better, but still very blue in the face and finger-tips. He told me he had not passed urine for twenty-four hours, and that he had frequently not done so for a similar period since working at the manufactory; during the day, however, he passed a small quantity, having a strong smell of almonds. During the week the blueness of the face &c. gradually disappeared and micturition became normal, and he returned to his usual state of health.

There have been five men employed at these works, of whom three have been under treatment for poisoning,[1] and all the patients recovered on being withdrawn from this work.

Sicherheit appears to be nitro-benzene $C_6H_5(NO_2)$, or dinitro-benzene $C_6H_4(NO_2)_2$, derived from benzene or benzol C_6H_6 by the substitution of NO_2 or $(NO_2)_2$ for one or two atoms (as the case may be) of the hydrogen of the benzene. Nitro-benzene or dinitro-benzene is made by acting on benzol with nitric acid. The smell of almonds to which the patient particularly drew my attention is remarkable, and is easily accounted for: the alcohol $\left.\begin{matrix}C_6H_5\,CH_2\\H\end{matrix}\right\}O$ benzol alcohol may be obtained by acting on oil of bitter almonds (C_6H_5COH, aldehyde of benzyl group) by alcoholic potash, &c.

Rotherham.

ABSENT RECTUM IN AN INFANT.

By OWEN PRITCHARD, M.D.

WELL-AUTHENTICATED cases of successful colotomy, or Littre's operation for absent rectum in infants, are, I believe, rare, and my notes of the following case may be of interest.

On May 6th I was sent for to see Mrs. B——'s baby, a boy nearly forty-eight hours old. The mother had been attended in her confinement by a midwife, who stated that, although soap injections had been used, the infant's bowels had never acted, there had been constant vomiting since birth, and that he was now sick unto death, and certainly he looked like it. On examination, the child was found to have the anus and lower part of the rectum perfectly normal, but, on passing the finger an inch or an inch and a half up, the bowel was found to end in a cul-de-sac, and no pulsation or any evidence of bowel above could be felt when the infant cried, though there was enormous distension of the abdomen; it was therefore thought perfectly hopeless to attempt any operation from below, the only alternative being colotomy. The left groin was selected as the most convenient situation for an artificial anus. The child being placed under the influence of an anæsthetic, the operation described by Littre was performed. As soon as the abdominal cavity was opened the bowel protruded prominently, and after being well secured by carbolised silk sutures to the peritoneum and skin, it was opened, when a free motion was immediately passed. The sickness stopped, the distended abdomen became flaccid, and in another twenty-four hours the infant began to look healthy and to take its bottle greedily. On May 8th the bowel had prolapsed about an inch and a half, but was returned after some difficulty, and the nurse was ordered to be more careful in keeping a firm pad over the opening to prevent another accident. Things went on well until May 20th, when I was asked to see the child. The nurse having neglected her instructions, I found the bowel had again prolapsed, this time two or three inches, and had been down some considerable time; it looked almost black, was swollen and bleeding, and was not reduced without great difficulty. After this everything went on well, the little patient looking very healthy and strong.

The tendency to prolapse in such cases, it seems to me, is a difficulty likely to continue, and to remain a source of anxiety and possible trouble in the future; and had I adopted the plan suggested by Mr. Allingham, of drawing down the bowel as far as it would come before opening the same, the operation might probably have been equally successful and this permanent source of danger avoided.

ST. GEORGE'S HOSPITAL.

A CASE OF LEPROSY; DEATH FROM PNEUMOTHORAX; REMARKS.

(Under the care of Dr. CAVAFY.)

WE published in a recent issue of THE LANCET notes of a case of leprosy which had proved fatal from pyæmia, and in which the laryngeal disease necessitated the performance of the operation of tracheotomy.[1] We give below notes of another case of typical character which was under observation in London, the patient dying from pneumothorax secondary to tubercular disease of the lungs. Death in these cases seldom occurs directly from the disease itself—dysentery, renal or lung disease being the commoner causes of a fatal ending. No danger to the other patients results from a case of leprosy in a ward of one of our modern hospitals, and the few cases which come under observation in London are better treated in the general wards than they would be in a special ward set apart exclusively for the treatment of such cases. Leprosy is regarded as an incurable disease, and the record of a single case of recovery does not justify the giving of other than a bad prognosis. The contemplation of patients suffering from a more advanced condition of the same malady, with all its worst features, could not fail to produce an amount of mental depression most harmful to those in the earlier stages, and the combating of this mental state is already a difficult task in those who know the nature of their disease. We are also of opinion that for purposes of clinical teaching it is better that such cases should be distributed as much as possible amongst the hospitals to which medical schools are attached. We are indebted to Mr. E. Le Cronier Lancaster, M.B., M.Ch. Oxon., for the notes of the following case.

William R——, aged twenty-four, was admitted into the William King ward of St. George's Hospital on Aug. 25th, 1888. His family and personal history were good. As far as he knew, there had been no phthisis in his family. His parents are English, but he was born on the Coromandel Coast, and when a baby was taken to St. Thomas's Mount in the Madras Presidency, where he remained until seven years of age, when he came over to England. He enlisted as a drummer-boy at the age of fourteen, and again went out to India at the age of sixteen, and was quartered in Bellary, in the Madras Presidency. He had only been there five months when he first (March, 1880) noticed swellings on both cheeks. The swellings were about the size of large marbles; they remained for about six weeks, and then disappeared. Swellings about the same size then appeared over the front of both thighs, and were so painful as to prevent his walking. A continued fever next attacked him, and lasted three months; he says the doctors never could get his temperature down, and that he was in a "continual heat." He was in the hospital from the end of March, 1880, until the August of that year. As he was still very weak, he was sent up into the hills to do infantry duty, and remained there nearly two years. No new swellings appeared, but the sites of the former ones grew quite dark, the pigmentation remaining for some months. He was then sent back to Bellary, and soon afterwards had another continued fever lasting about three months. In 1884 new swellings appeared on his back and on his legs. In 1885 he noticed that his voice altered and became hoarse, and the alteration has been permanent. In

[1] THE LANCET, vol. ii. 1889, p. 166: Mirror of Hospital Practice.

Digitized by Google

1886 the first phalangeal joints became much enlarged. In the same year he was again in the hospital, this time for laryngeal catarrh, and whilst there noticed that lumps developed very rapidly—"in the course of a few hours"—over his chest. According to his own account he was then for the first time diagnosed as having leprosy, by a civilian doctor. He was discharged from the army in August, 1887, and since his discharge the swellings have become much more numerous. He has never noticed any anæsthetic patches. He says that the swellings "come and go," and he has noticed them develop, especially whenever he is constipated. Since leaving the army he has lost much flesh. For the last three weeks he has had a bad cough, and sweats much at night. He is subject to attacks of general pruritus, coming on about once a month, and lasting for two or three days. He complains of increasing weakness, but thinks that of late the leprosy has not increased, and considers that he has good general health.

Condition on admission.—Looks much older than he is—say fifty-five. Has a typically leonine aspect. The skin of the face is yellowish, shiny, and smooth. He has no moustache, whiskers, or eyebrows. There are a few hairs under the skin. The conjunctivæ are slightly yellow. There is much thickening of the subcutaneous tissue of the eyebrows, nose, cheeks, and ears. The lobes of the ears are enlarged, flabby, and pendant. There is hardly any bridge to the nose. The facial furrows are much deepened. The tongue shows three small patches near the tip.—Thorax: Skin smooth and yellowish. There are numerous discrete copper-coloured tubercles, situated in and just beneath the skin, scattered universally over the front of the trunk. There is a scab on an inflamed base on the right elbow, and a large red scaly patch resembling psoriasis over the left elbow.—Arms: Very numerous tubercles, varying in diameter from a pin's head to a fourpenny-piece, on the extensor surfaces of the upper arms, also several maculæ; these maculæ are of various shades of pigmentation—red, brown, black, and a few white. The skin over the backs of the hands and wrists is thickened, red, and in parts scaly. The first phalanges are enlarged, seemingly from skin-infiltration. The nails are all cracked and broken.—Abdomen shows numerous tubercles and maculæ.—Back: There are numerous tubercles and maculæ, especially over the buttocks. Some of the maculæ display a white centre, surrounded by a dark ring.—Legs: Tubercles are scattered all over the thighs. In each ham is the scar of an old ulcer. There are four ulcers over the ankles and lower part of the legs. The largest of these is about four inches long by two inches broad. They have a sodden, white, raised margin, are covered with feeble granulations, and exude much pus. The skin of the foot has a tendency to peel, and the nails are badly nourished.—There are two or three small anæsthetic patches on the extensor surfaces of the arms, one of which is not larger than a pea. Nothing abnormal was detected in the heart or abdominal viscera. A few doubtful clicks were heard at the apices of the lungs. The throat was examined with the laryngoscope, the mucous membrane of the arytæno-epiglottidean folds was thickened and tuberculated, and prevented any view being obtained of the vocal cords.

Course and treatment.—The man remained in the hospital until the beginning of January. During the whole of the time his temperature was very irregular, varying between 96·6° and 102·6°. Whenever the fever showed exacerbation, new tubercles appeared, principally on his thorax, back, and arms. The evening temperature was usually the highest, but occasionally the maximum point was reached about 3 P.M. Salicylate of soda was tried in simple doses three times a day, but the administration of this drug was promptly followed by the worst exacerbation of fever, and the most rapid development of tubercles that occurred during his whole stay in the hospital, and after a week's trial it was given up. He seemed to derive benefit from Chaulmoogra oil in doses of fifteen grains three times a day, and also from the outward application of equal parts of Gurjun oil and olive oil. Carbolic acid lotion, boracic acid, and iodoform were tried for the ulcers, of which the latter was by far the most successful, and when he left the ulcers were almost healed. He had a constant cough, due to laryngeal irritation, as nothing definite was ever heard in his lungs. His general health improved very greatly, and he was mainly instrumental in decorating the ward at Christmas. During his last six weeks the temperature was more regular, not rising above 100°; his urine was free from albumen. He went from St. George's to St. Thomas's, where he remained some months.

He presented himself for readmission at St. George's on May 29th, 1889. The leprosy had decidedly improved, there were fewer tubercles, and his aspect was much less leonine. But he was very low and ill, partly from starvation (as he was unable to live on his pension, and could get no work), but principally from phthisis. Both lungs were extensively diseased, and he was much emaciated. He was treated almost solely for the lung mischief, but after a temporary improvement he gradually got weaker, and died on July 13th, having developed a left pneumothorax a few days previously.

Remarks by Mr. LE CRONIER LANCASTER.—This case was a typical example of the tubercular variety of leprosy, and ran a characteristic course. The development of the tubercles during the febrile attacks was very well marked. The slight amount of anæsthesia was curious; he was not aware of it himself until it was demonstrated upon him. That there was, however, some interstitial neuritis is probable from the fact that the swollen ulnar nerve could be plainly felt behind each condyle. Dr. Sheridan Delépine, however, has various specimens of the tissues in preparation for microscopical examination. There is no doubt that his leprosy *per se* was considerably better when he died than on his first admission 11 months previously, and the improvement dated from the administration of the Chaulmoogra oil and the application of the Gurjun oil. Salicylate of soda, which has been much recommended for the reduction of the leprous pyrexia, failed so signally that it was not considered advisable to give it an extended trial. His disease was not inherited, and he stated that though leprosy was frequent among the natives at Bellary, yet he knew of no other European having been attacked. I must thank Dr. Cavafy for his kind permission to publish the case.

CITY HOSPITAL (SOUTH), LIVERPOOL.

TWO CASES OF SCARLATINAL NEPHRITIS, FATAL FROM MENINGITIS; NECROPSY.

(Under the care of Dr. W. IRVINE.)

THE occurrence within a short space of time of two cases similar in many respects, and illustrative of a rare sequela of scarlet fever, makes them of sufficient interest for publication. How far the later symptoms were due to uræmia, and how far to meningitis, and the question of the pyæmic origin or otherwise of the meningitis, are not easily determinable. For the account of these cases we are indebted to Mr. C. Knox Bond, resident medical officer.

CASE 1. John F. C——, aged five years, was admitted to the hospital on the 3rd of June, 1889, suffering from scarlatinal nephritis. The parents stated that the child had had scarlet fever, with definite red rash, and sore throat followed by desquamation, five weeks previously. The attack was mild, and the boy had been up and about until five days previously to admission, when he had a fit, followed by vomiting frequently repeated during the next two days. He appeared ill, was breathing rapidly, expiration being attended by expulsive effort, the face pale, aspect dull and heavy. The skin was dry, presented no rash and very slight indication of desquamation on the lower extremities and the palms of the hands. No œdema beyond very slight puffiness on the dorsum of each foot, said to have been noticed previously to admission. Lungs: Resonance impaired over left chest, especially back; movement good; a few bronchitic sounds over left lung. The heart sounds were sharply accentuated at the base and apex. Pulse 140, hard. The urine contained a very slight shade of albumen, treated with picric acid; and gave no blueness with guaiacum and ether. The tongue was thickly coated along the dorsum, yellow; edges clean and moist. Temperature 103·4°. The child remained in much the same condition until June 9th, when the apex of the right lung became consolidated, slight left otorrhœa commenced, and diarrhœa supervened. On the night of the 10th he became very dull, with slight intervals of restlessness and delirium, and was very cold and collapsed, the temperature falling in a few hours from 102·8° to subnormal. This condition was attributed to the effect of the application of ice to the abdomen to check the diarrhœa; on discontinuing this treatment the temperature again rose and the collapse abated. The lung consolidation rapidly

Digitized by Google

spread downwards, until signs were present over the entire front and upper scapular region on the right side. The heart's action became very irregular and laboured; the pulse 128, and correspondingly irregular; the pupils were large, equal, and very mobile. The discharge from the ear had ceased. The child became more dull, and the evacuations were passed involuntarily. After 11 P.M. on the night of June 12th the temperature, previously normal for some thirty-six hours, commenced to rise, reaching a maximum of 105·8° at 5 P.M. on the following day, and remained high till death took place at midnight. This sudden onset of fever was associated with vomiting, profuse sweats, free discharge from right and left ears, repeated convulsions, and coma, which preceded death.

Necropsy, thirty-five hours after death.—Thorax: There was slight excess of fluid in the pericardial sac and dilatation of the ventricles of the heart; no valve lesion. The right lung was adherent over the front, the adhesions soft and recent, the upper lobe solid, and in a condition of red hepatisation. On removing the skull-cap the membranes were found to be much congested, the dura mater slightly adherent here and there at small patches along the longitudinal sinus, where recent lymph had been thrown out, chiefly about the middle of the sinus. The brain substance generally was soft, swollen, and œdematous, and there was slight excess of fluid in the ventricles. No indication of extension of ear suppuration was observed about the temporal bone. No scattered abscesses elsewhere in the organs or other evidence of pyæmia. The kidneys presented the usual appearances in nephritis.

CASE 2.—Emily H——, aged five years, was admitted to hospital on July 2nd, 1889, suffering from scarlatinal nephritis. The primary illness had been mild, the patient never having been kept in bed. A red rash was the only symptom noticed three weeks before admission. A younger child, a sister, had died convulsed at home a few days before this child was brought to the hospital. On admission, the child appeared ill, but was sensible, and could walk. She was desquamating about the hands and feet; the skin was dry. There were general anasarca, ascites, and lung œdema, with pleural dropsy. The heart-sounds were clear. The mother said she had had ear discharge, but none was then present. The tongue was clean, papillæ just red and prominent. Pulse 102; tension increased; regular; respiration 70, easy. Cough single, frequent. Temperature 101°. Urine scanty, showed slightest trace of albumen with picric acid; no blueness with guaiacum and ether. The child improved gradually under treatment, the dropsy almost entirely disappeared, the lung condition amended, the skin became moist, and the child less pale and lethargic, the pulse becoming softer and less frequent; vomiting, which was a rather troublesome symptom, ceased, and the temperature fell to normal. The improvement continued until the early morning of June 10th, when, after a fairly good night, the child was noticed to be not so well, having become very dull, breathing with effort and rapidly; was restless, grinding her teeth, biting her hands, screaming out at times, rolling her head about, and between 9 and 10 A.M. she became unconscious, remaining so until 1.30 A.M. on the following morning, when she died. The temperature commenced to rise after 7 A.M. from normal, reaching 101·8° at 11 P.M. The pulse became very irregular and intermittent, hard, scarcely to be counted, at the wrist 100. Convulsions appeared impending several times, slight twitching taking place; baths were given frequently and free purgation. Nitro-glycerine relieved the vascular tension, and the child died without actual convulsion taking place. The eyes became fixed, wide, pupils dilated, and equal. There was no vomiting. At the necropsy held on the day following death, the appearances of the brain and membranes were almost identical with those seen in the previous case, the amount of lymph thrown out towards the middle of the longitudinal sinus being in excess of that then seen.

RABIES. — According to the *London Gazette*, the number of dogs in England reported during the week ending the 10th inst. as afflicted with rabies was 13 against 15 in the previous week. Of these, 9 were killed and 2 died. The remaining two cases existed in previous weeks, but were not reported until this week. Of the 13 diseased animals, 2 belonged to Hants, Kent, and Lancaster respectively, 3 to London, and 1 each to Kent, Middlesex (excluding London), Oxford, and York (West Riding).

Reviews and Notices of Books.

On Bronchial Asthma: its Pathology and Treatment. By J. B. BERKART, M.D. Second Edition. London: J. & A. Churchill. 1889.

THE subject of asthma is a fertile field for hypothesis, and many have been the theories advanced to explain its paroxysmal character and the varied conditions which apparently favour its occurrence. Among them all that which has gained the widest acceptance, which not only harmonises with the clinical phenomena and morbid associations of the affection, but which seems to be fully confirmed by the results of treatment, is that of bronchial spasm. It would be idle to deny that this theory is free from objection on the physiological side, but that it is competent to account for the phenomena of the attack and to explain the action of remedies is certainly true. The great exponent of the doctrine in this country was the late Dr. Hyde Salter, whose work on asthma ranks amongst our medical classics. It is well worth taking down from the shelf, to re-peruse its vivid descriptions, before turning to the monograph by Dr. Berkart, of which the second edition is now before us. The reader will then be the better able to judge whether the facts and reasonings advanced by Dr. Berkart are sufficiently weighty to overturn the views held by his predecessor; and we may hope that Dr. Berkart's able and highly interesting essay will incite others to follow his example, and to study the phenomena of the disease untrammelled by preconceptions or prejudice.

There is much that is excellent in Dr. Berkart's volume. Nowhere, we think, will be found so elaborate and careful a study of the sputa of the asthmatic, a description which is enhanced by drawings of great beauty and delicacy. Dr. Berkart lays great stress upon the characters of the sputum, for they reveal much, he thinks, of the true nature of the affection. This he holds to be essentially inflammatory in nature, and he avers that the process invariably spreads from above downwards. There is, indeed, no question that in the majority of cases the bronchial "spasm" is preceded by symptoms of irritation of the naso-pharynx. Violent sneezing is often a precursor, by years, of the onset of asthma, and many an attack is ushered in by the symptoms of nasal catarrh. Nevertheless, cases do occur where the dyspnœal paroxysm arises suddenly, and without premonitory symptoms of any kind. Dr. Berkart's view is that the inflammatory process involves changes in the epithelial lining of the bronchi, accompanied by a croupous exudation, as evidenced in the casts and spirals which are expectorated during or at the close of an attack; and that the dyspnœal paroxysm is owing to the displacement of plugs so formed, and their lodgment in other parts of the bronchial tract. This detachment of plugs—he applies the term "embolism" to their transference—and the consequent obstruction to which they give rise, account, he thinks, in great measure for the expiratory difficulty, although he is quite prepared to accept a certain amount of superadded spasm, "bronchial tenesmus," owing to the presence of these obstructions. The cessation of the paroxysm is due to the free secretion of thin fluid, and the dilatation of the bronchi, allowing of the escape of the plugs of mucus and epithelium. This ingenious doctrine is supported by the carefully described dissection of the lung of one case, where such a plug was found, together with secondary changes in the bronchioles and alveoli, and it is, moreover, applied to the circumstances of the attack. In order, however, to establish it the author is compelled to thrust aside as "romance" and "imagination" the greater portion of the exciting and predisposing causes hitherto alleged to exist. For him "hay asthma," in so far as it is due

Digitized by Google

to pollen, is a fable; whilst the statements of attacks induced by particular odours, by special climatic influences, and all the "alleged capriciousness" of the affection are brushed aside as unworthy of credence. Even the avowed relationships of the asthmatic paroxysm to gastric disturbance and to cutaneous disease, to gout, or to rheumatism, are similarly dismissed, the latter as coincidences, the first-named as being merely the effect of increased respiratory movement entailed by a full meal, such movement leading to the detachment of the croupous plug.

What idiosyncrasy there is in asthma lies, then, on this hypothesis, in the readiness with which the bronchial mucous membrane is liable to undergo this specific change. It is possible—and the discovery of streptococci in the sputum suggests it—that the real exciting cause is a micro-organism allied to the streptococcus erysipelatis. But Dr. Berkart does not press this suggestion. He lays considerable stress upon the type of conformation of the chest, which he attributes to previous rickets, and the small ill-developed lungs that are associated with this. He regards the frequent association of nasal polypi with asthma as confirmatory of his view, since they are evidence of repeated irritation of the mucous membrane; whilst the effect of their removal in checking asthma (which has, he thinks, been over-rated) is attributed to the retention of secretions to which their presence gives rise. With such views it is obvious that Dr. Berkart must and does regard most of the current treatment of the asthmatic paroxysm as ill directed. Some of it, indeed, he holds to be directly harmful, as increasing the liability to congestion of the respiratory tract. Antispasmodics are of quite secondary importance; morphia is advocated as the best measure to relieve the "bronchial tenesmus"; and other remedies, if efficacious at all, owe their efficacy to their expectorant or stimulant properties. Even iodide of potassium, so much praised by many physicians, has been disappointing in his hands. Climatic treatment is discounted; the reasons alleged that a patient is free from asthma at one place and not at another (common as that experience is) are held to be formed "on a hasty conclusion, based on the flimsiest of grounds." It is invigorating to meet with so stern an iconoclast as the author shows himself to be; and, whether the reader agree with his dicta or not, he will not fail to find much enjoyment as well as profit in the perusal of Dr. Beckart's monograph. It is obviously the product of close personal observation and study of the affection. There is always room in medical science for the honest expression of diversity of opinion, especially when based on reasonable argument.

A Text-book of Medical Jurisprudence for India. By I. B. LYON, F.C.S., F.I.C., Brigade Surgeon, Bombay Medical Service; Chemical Analyser to Government; Professor of Medical Jurisprudence, Grant Medical College, Bombay. Revised as to Legal Matter by J. D. Inverarity, Esq., Barrister-at-law. Pp. 557. Calcutta: Thacker, Spink, and Co. London: W. Thacker and Co. 1889.

THE above work is an admirable exposition of the science of Medical Jurisprudence generally, but its special value lies in the fact that it has been written for the purpose of guidance for medical men practising in India.

The subject matter has been arranged with great care, the classifications of poisons being especially worthy of notice. For example, we find special poisons divided into two chief classes. Group I.: Central poisons, including strychnine, Calabar bean, gelseminum, and methyl-conia. Group II.: Peripheral poisons, under which head are placed conium, curare, and aconite. Of course this method of classification implies much "cross division," but for all that it gives at a glance the primary and chief action of the poisons, and incidentally their physiological antidotes. The chapter on "Legal Relations of Insanity," though occupying only eleven pages, is a capital exposition of the subject. It is prompted by intimate knowledge of the question, and is handled with care and precision.

Towards the end of the work is a valuable series of illustrative cases. Those relating to arsenic poisoning may be studied with advantage by readers interested in the Maybrick case.

The book reflects great credit on the author and publishers. The letterpress is excellent—large bold type; and the illustrations are accurate representations of the originals. The diction is clear and concise, and is well worthy the author's reputation.

THE BRITISH MEDICAL ASSOCIATION.

THE SECTIONS.

MEDICINE.

ON Wednesday, Aug. 14th, the Section of Medicine was opened by the President, Dr. EDDISON, who, in the course of a brief address, expressed his regret at the many subsections into which medicine was divided, leaving only a very narrow range for 'medicine proper. His remarks to this effect were received with evident approbation by the members present.

The first paper was by Dr. DOUGLAS POWELL, on the subject of Chronic Tubercular Diseases of the Serous Membranes. He alluded to his subject as one of arbitrary limits, including cases not acute, in which the disease was in the first instance limited to one serous membrane, spreading perhaps to others, chiefly through lymphatic paths; in which the fever, low in range, was of remittent or irregularly intermittent type, the intervals of apyrexia being often long; in which the constitutional state was that common in tuberculous subjects of the erethic type, with quickened pulse, harsh dry skin, wasting body, and associated with which phenomena were the local signs and symptoms of the disease. Tubercular disease of serous membranes was rarely primary; if general, a forgotten mass of old tubercle was usually in the background; if local, there was commonly precedent disease of the subjacent or neighbouring organ. He accepted as satisfactory the views of Mr. Barker, who admitted the tubercle poison as disseminated in the blood current; and, on the other hand, accepted a receptivity or preparedness of tissue of more or less embryonic conformation in young people, the embryonic type in adults being represented by the young cells of plastic exudations. He was inclined, however, to attach more importance to activity of growth and functions in certain parts at certain ages, as rendering them liable to the onslaught of tubercle in those hereditarily or by evil conditions of life predisposed. Tubercular meningitis as a chronic disease was in his experience almost unknown. Tubercular pleurisy was by itself, as shown by post-mortem examinations, a rare disease. Was it so rarely met with clinically? It was well known that pleurisy commonly preceded phthisis, but were not such cases of pleurisy in the first instance tubercular, and, indeed, secondary to tubercle present in the lung? He was increasingly inclined to think so, and related two cases illustrative of his experience. In one of these cases the clinical history suggesting possibly-old tubercular lesion was corroborated by the discovery by Dr. Wethered of elastic tissue encrusted with lime salts in the sputum. There were no clinical rules of very precise application for the recognition of tubercular serous effusions. The insidious onset and symptomatology, the preceding symptoms, the duration, and the possible affection of other membranes were in point. Dry pleurisy at the apex should be always regarded with suspicion, Dr. Burney Yeo had described three interesting cases of apex pleurisy in young people, attended with peculiar hard coughs, and in one with some stained mucous sputum, all of which got well, What was Dr. Yeo's experience of the future of such cases? It

Digitized by Google

was difficult to recognise slight pulmonary changes, especially in the presence of effusion; examination of the sputum, if any, would help, but a continuing slight febrile action and persistently-quickened pulse were of much importance, a secondary rise of temperature after the third week being (empyema excluded) very significant. The appearance of the fluid was not characteristic. It was mostly clear, sometimes smoky or blood-stained, or opalescent, not often purulent, excluding cases of perforation. Examination of the fluid for tubercle bacilli had proved unsatisfactory, the organisms not having been found in many cases whose tubercular nature was otherwise demonstrated. He related a case in which after several failures, bacilli had been found in certain tiny flecks of an otherwise clear effusion. This experience, and that of a case some years ago, in which, after failing to find bacilli in the pus of an empyema, plenty had been discovered in a drop removed on the point of a probe from the pleural surface, led him to believe that the bacilli germinated chiefly in contact with the pleural surface, and were not to be found free in the effusion, except in minute flecks or sheddings from that surface. Cultivation and inoculation experiments were also at present not to be trusted in diagnosis. The case he related was also one in which rapid absorption and recovery had ensued, although the effusion was distinctly tuberculous. He thought he had observed many such cases. What was their future? With the practical rest brought about by adhesions, and in the absence of fresh pabulum, the bacilli became extinct or dormant and the tubercle underwent fibroid degeneration, so that indefinite quiescence might be hoped for. The disease might recur in another membrane or in the lung, but not necessarily in the same lung. Phthisis advanced by a succession of attacks, and any temporary lull might become permanent quiescence. Caseation was comparatively rare in serous membrane tubercle. In chronic tubercle of the peritoneum, with similar constitutional symptoms, we observed colicky pains, intestinal flatulence, irregular or relaxed bowels, enlarging abdomen with impaired resilience and elasticity, and a doughy resistance and movement *en masse* under palpation significant of intestinal adhesions, slight tenderness, and sometimes peritoneal friction sound. The effusion often proceeded to ascites, and in some cases, after a time, the physical signs became remarkably altered, the resonant intestines being held back to the flanks. In such cases the diagnosis from ovarian cyst was often very difficult. The fluid might be absorbed, and the patient recover, as not infrequently happened; or in what might be regarded as the third stage, signs and symptoms arising from contractile deformity of the omentum and mesentery ensued; masses or bands were to be felt resembling cancerous masses; contortions, irregular peristalsis, and obstruction (partial or complete) due to constriction by or entanglement around the contracted or thickened bands occurred. In other cases perforation of the intestine and localised abscesses, perhaps pointing through the abdominal wall, took place. Dr. Fenwick had found ulceration of the intestines recorded in only eight of his forty-seven collected cases. He (Dr. Powell) thought that ulceration or tuberculous disease of some (often a pelvic) organ was more usually present. In discussing the treatment, Dr. Powell alluded to the scanty growth and feeble vitality of serous membrane tubercle and its tendency to obsolescence. The dangers were from inflammatory damage to subjacent organs and from contortion and strangulation of vital parts; in other cases from perforations and suppurations. Nothing at present known would cure tubercle; the bacillus would cheerfully withstand antiseptics in doses beyond the toleration of his host. Mercury was the most hopeful antiseptic, but reduced the resisting powers. Mechanical rest to chest or abdomen with good hygiene was very important. On the question of opening the abdomen we were collecting experience, and in forming a judgment it should be remembered (1) that many cases had a favourable issue under careful treatment; (2) that the tubercle could not be removed by operation, arrest and obsolescence being all that could be hoped for; (3) that the successful cases hitherto met with were cases in which the peritoneum had inadvertently been opened in non-suppurative cases; (4) the cases most needing surgical help were those analogous to empyema, in which, however, the presence of perforations and intestinal ulcerations often rendered such treatment of doubtful utility. The matter was one for very useful discussion and new experience.—Dr. HANDFORD agreed with Dr. Powell that we have no direct treatment which will injuriously affect the tubercle bacillus. It produces changes which are closely analogous to, and in many cases indistinguishable from, those of actinomycosis and syphilis. It is these changes which we must treat on their merits, independently of the bacillus itself. Sufficient importance has not been given to the very varied course which the bacillus runs in the different lower animals. As a general rule, it tends to be a more localising affection in the animal feeders than in the vegetable. There is much reason to believe that something of the same kind is true in the human subject. He doubted whether those cases of tubercular peritonitis where a caseous affection of the omentum and mesenteric glands, without any great effusion of fluid, is the prominent feature, would be benefited by abdominal section. Dr. BURNEY YEO spoke of the occurrences of dry pleurisies of the apex, which he had studied for some time. He believed that some apical pathological conditions, which were really pleuritic in origin and not tubercular, were mistaken for the early stage of phthisis. They were really rheumatic in origin, and ran a different course from tubercular disease. They were prone to occur in persons of rheumatic tendencies, and recovered perfectly, as did many rheumatic affections of the joints, by counter-irritation, blisters, and iodine, and iodide of potassium internally. He called attention to the analogies, anatomical, physiological, and pathological, between synovial and serous membranes. He believed in the value of antiseptic agents in the treatment of tubercular affections, though he did not believe that they acted as germicides.—Dr. BROADBENT had not heard Dr. Powell's paper, but, having seen an abstract, he was in complete agreement with him in all important points. He brought before the Section only his experience on the subject of opening the abdomen in tubercular peritonitis. He had had this done in several cases, and, although he had not seen the remarkably good results which had now been so often obtained, there had always been relief, and, except in one case he considered that life had been prolonged. He had come to the conclusion that the tubercle bacillus was a vulnerable organism if it could be got at, and that the difficulty in the treatment of phthisis and other tubercular disease consisted in the fact that remedies administered by the mouth or by inhalation did not reach the organism. He had seen no good results from the so-called antiseptic treatment of phthisis.—Dr. C. GAGE BROWN had seen cases of pleurisies of the base followed by phthisis at the apex, not necessarily on the same side. Post-mortem examinations in some of these cases had only shown evidence of old-standing non-tubercular pleurisy of the base.—Other speakers followed, after which Dr. Powell replied.

Dr. C. R. DRYSDALE read a paper upon the alleged Rarity of Phthisis among London Jews. As the result of extensive inquiries among Jewish practitioners of medicine, he had come to the conclusions—(1) that Jews suffered less from phthisis than the ordinary inhabitants of London; and (2) that the evidence was strong that this was in part due to the exclusion of tuberculous meat from their diet, owing to strict inspection; hence the importance of a wise examination of all animals used for food, and especially cattle.

At the meeting on Thursday, Aug. 15th, Dr. PAVY read a paper upon the Prognosis of Cases of Albuminuria, with Special Reference to Life Insurance. (This paper will be found printed *in extenso* at page 361 of our present issue.) The following discussion took place:—

Dr. MAGUIRE would speak of two classes of case. 1. Cases of functional albuminuria with high-tension pulse, but without any other evidence of disturbance of health. These cases were found at all periods of life. In the young there was usually a family history of Bright's disease. The amount of albumen varied throughout the day. 2. Cases with low arterial tension, in which some debility was usually present. There were no cardiac changes. The albumen might be present in large quantities. It was "cyclic" in occurrence, and was influenced by exercise. Hyaline (never granular) casts might be present. The albumen mght be wholly globulin, but the kind of albumen was not sufficient to distinguish functional albuminuria from organic disease. The prognosis was bad in the first case, more favourable in the second, but an increased premium should be required.—Dr. PYE-SMITH agreed with Dr. Maguire that the presence of globulin without serum-albumen was favourable. He thought albuminuria was never truly physiological, but always indicated a falling short of the standard of health.

Digitized by Google

It was influenced by repose, cold, and food, but not in his experience by emotion. Casts might be present without organic disease. There might be Bright's disease without albuminuria. Some of the cases of functional albuminuria were really cases of hæmatinuria. Albuminuria might be compared with hæmoptysis, inasmuch as its occurrence only suggested disease. The business of a medical referee of an insurance company was to exclude all cases in which there was a reasonable doubt. In ordinary prognosis we might fairly incline a little more to optimism. We could hardly hope to exclude with certainty early Bright's disease from cases of functional albuminuria. Cases should be deferred and re-examined before a definite opinion was given. — Dr. GAIRDNER was still unconvinced that we could talk of functional albuminuria. He did not object to the term "functional albuminuria," if by it was meant an albuminuria which was not necessarily accompanied by demonstrable changes in the kidney. In Weston's case, related by Dr. Pavy, the strain was unphysiological. He held that the presence of albumen in the urine was a danger signal. The amount of the danger varied enormously. He thought the occurrence of albumen in typically healthy persons was a rare event. In insurance such cases should be postponed and the medical attendant of the applicant communicated with.—Dr. RABAGLIATI thought the presumption was against the life if albuminuria were present. If casts were also present there should be a heavy increase of premium in the young and absolute rejection in the old. We must remember that the better classes, who comprised the great majority of applicants for insurance, had more than their due proportion of renal disease owing to their large consumption of nitrogenous food and alcohol.—Dr. DRYSDALE thought we were becoming rather optimistic in this matter. The time was hardly ripe for drawing the line very sharply. All cases of albuminuria in candidates for insurance should be postponed for detailed examination.—Dr. CRANSTOUN CHARLES gave some statistics regarding the occurrence of albumen in his experience. In 250 apparently healthy students he had found albumen present in the mid-day urine of 34 (13·4 per cent.). In 72 pupils of a training college, he had found albumen in the after-dinner urine of 24. In half of these cases peptones were present. In 110 candidates from the country, coming up to London for examination, he found albumen in the morning urine of 30. He had seen albuminuria due apparently to tight-lacing, to constipation, to hard work in clerks and shop-girls, and to rowing and football.—Dr. SAUNDBY was gratified at the results of the discussion, and hoped it would serve to mitigate in some measure the gravity of our prognosis in albuminuria. He was a firm believer in a form of albuminuria which was innocent. He suggested the term "mechanical albuminuria," as posture had something to do with it. As regards casts, it was their number and frequency which gave them importance.—Dr. TYSON deprecated the amount of anxiety which the advance of knowledge regarding albuminuria was causing many persons. He thought the comparatively small number of deaths from Bright's disease compared with the large number of cases of albuminuria that came under notice was an indirect proof that many of the latter get well. Cases should be carefully watched and reported, but the premature recording of abuminuric cases as cured should be strongly deprecated.—Dr. BARR thought that too much attention had been given to albumen, to the neglect of the other constituents of the urine. He thought the real defect was nominally circulatory. The quantity of urea present was most important.—Dr. GEORGE HARLEY paid great attention to the specific gravity, since it was not the excretion of albumen which killed, but the retention of the excrementitious salts. If the specific gravity were above 1015 he treated the albuminuria as probably curable. He objected to the terms physiological or functional albuminuria.—A communication was read from Dr. GEORGE JOHNSON, in which he gave it as his decided opinion that all albuminuria was pathological.—The PRESIDENT (Dr. Eddison) advised that no case should ever be passed without postponement. He doubted if albuminuria were ever due to excitement.—Dr. PAVY replied.

On Friday, Aug. 16th, Dr. ARMAND RUFFER, of the Pasteur Institute, Paris, read a paper upon Pasteur's Method in Hydrophobia. He adverted, in commencing, upon the great interest felt in the subject of hydrophobia in spite of the rarity of the disease, an interest due to the facts that a person bitten by a rabid dog was often kept for months in suspense as to the issue, and that, if the smallest genuine symptom of hydrophobia made its appearance, the victim was doomed to one of the most painful and horrible of deaths. Since Pasteur's discovery in November, 1885, twenty anti-rabic institutes had been founded in various parts of the world, including Naples, Palermo, Odessa, St. Petersburg, and Havannah. The virus of hydrophobia was probably a particulate virus, and due to a micro-organism. The only absolutely sure method of inoculation was under the dura mater. The bites of rabid dogs never healed by first intention, whereas the wound from an inoculatory injection had never been known to cause an abscess. A point of very peculiar interest in the disease was the very variable and often prolonged period of incubation. Statistics showed that 20 per cent. of those bitten developed the disease within one month, 50 per cent. within two months, 70 per cent. within three months, and 90 per cent. within four months. One case had died after a lapse of fifteen months. Twenty-seven months was said to be the extreme limit, and such prolonged periods of incubation were very rare. The shortest period known was thirteen days. The symptoms of the disease were divisible into three stages: (1) A stage of melancholia, with pain at the seat of the wound; (2) a stage of convulsions; (3) a stage of muscular weakness and paralysis. The symptom which had given the name to the disease—viz., hydrophobia—might be quite absent. It was exceptional in dogs and invariably absent in rabbits. The paralytic form of the disease, which was the rule in rabbits, was not very rare in man. The prognosis was always fatal in the human subject if once the symptoms developed themselves. A dog had been known to recover twice from inoculated hydrophobia. If the virus were transferred from animal to animal the period of inoculation fell from eighteen days to six or seven days. It did not further shorten, and the virus was then said to be "fixed." Pasteur's treatment was of two kinds—viz., the simple and the intensive. In the former the patient was inoculated on the first day with virus from a spinal cord dried for fourteen and thirteen days, on the second day with virus from a spinal cord dried for eleven and twelve days, and on the fifth day with virus from a spinal cord dried for six days. In the second, or intensive method, which was specially applicable to face bites (as in these the incubation period was very short), four injections were given per diem, and on the third day a spinal cord dried for only six days was used. This method, though apparently more dangerous than the other, gave better results. Its aim was to bring the patient as speedily as possible under the influence of the inoculations. Pasteur never injected a cord dried only one or two days, but this was done at Odessa. The results of treatment at Paris and elsewhere were then given in great detail and in tabular form. First, as regarded the proportion of persons bitten by rabid animals who developed hydrophobia if untreated. A variety of statistics were given to show that from 15 to 20 per cent. of persons bitten by dogs or cats developed the disease, but from 60 to 64 per cent. of those bitten by rabid wolves. In face bites the mortality was very high, over 80 per cent. The results in cases treated by the Pasteur method were then given. Of 2164 persons treated at the Pasteur Institute from November, 1885, to January, 1887, only 32 had died—a mortality rate of 1·4 per cent.; 214 of these were bitten in the face or head—a class of wound in which, as already stated, the mortality was terribly high where no treatment was adopted. In all the above cases the animals inflicting the bite had been proved to be rabid. Of 518 persons bitten by animals supposed, but not definitely proved, to be rabid, and treated at the Pasteur Institute, only 3 had died, a mortality of only ·58 per cent. The mortality after using the simple method of treatment was higher—viz., 6·6 per cent. The results obtained at the anti-rabic institutes in other countries had been practically the same. In 484 cases treated at St. Petersburg the mortality was 2 per cent. In three sets of cases, numbering respectively 324, 345, and 364, treated at Odessa, the respective mortality rates were 3, ·58, and ·6. At Moscow three sets of cases, numbering 107, 208, and 431, had been treated, with a mortality of 8, 1·2, and 1 per cent. At the same place (Moscow) 70 persons bitten by wolves had been treated, with a mortality of 10 per cent. At Turin the recorded mortality was only ·56 per cent.; while at Naples, Palermo, and Havannah it varied from practically *nil* to a little over 1 per cent. Some further details of Pasteur's own results were given. In the year 1887 there

Digitized by Google

were treated 1778 cases, with a mortality of 1·3 per cent. in those who had undergone any treatment and of ·73 in those who had completed the entire course. Of face bites, 127 cases had been treated, with a mortality of 7·87 in those who had undergone any treatment and of 2·51 in those who had completed the course. In 1888 there were treated 1626 cases, with a mortality of 1·16 in those who had undergone any treatment and of ·55 in those who had completed the course. It was too soon to tabulate the results of treatment in 1889, but Dr. Ruffer thought the mortality would hardly exceed 1 in 500. In spite of assertions to the contrary, there was not the slightest proof that any case of disease had ever resulted from the treatment itself. As a proof that the inoculations were perfectly safe, he might mention that all M. Pasteur's assistants and laboratory workers had been inoculated, and that no case of hydrophobia had ever been known among them. Dr. Ruffer's lengthened address was listened to with profound attention by a large audience, and at its conclusion he was heartily applauded.—The following joined in the subsequent discussion: Dr. Drysdale, Dr. Saundby, Sir William Moore, Dr. Vaughan Harvey, Dr. George Harley, and others. The general sentiment of the speakers was one of warm admiration for M. Pasteur's labours, and a thorough endorsement of his results.

The PRESIDENT of the Section (Dr. Eddison) remarked upon the injustice of the British laws, which allowed all kinds of wanton cruelty to be inflicted upon animals for amusement or gain, while they hampered and impeded scientific experiments for the alleviation of human suffering and disease. A ratcatcher might leave his trap unwatched for a week, or a gamekeeper might set his rabbit-traps in the evening and go round next morning to take out the tortured animals, and all this without interference from the laws, while scientific experiments were under a ban.

Dr. RUFFER, in reply to some questions, said it was a total error to suppose that heat had any influence in the causation of rabies. The largest number of cases at the Pasteur Institute occurred in February and the smallest in August. The disease was not most prevalent in warm countries, but it existed in Russia. He strongly advised the muzzling of dogs, and believed that if this were universally carried out the disease would disappear in a couple of years.

SURGERY.

At the meeting on Wednesday, Aug. 14th, Mr. JESSOP delivered his address on Treatment of Cancer of the Rectum (see last week's issue, p. 333). In the discussion which followed, Mr. F. MARSH showed a patient on whom he had performed Madelung's operation.—Mr. MITCHELL BANKS regarded colotomy as often of great advantage in cancer of the rectum, but some patients went on very comfortably without operation.—Mr. HARRISON CRIPPS advocated early excision, and gave statistics in support of his views.—Mr. ALLINGHAM also advocated early proctotomy and inguinal colotomy, if the case were too far advanced for excision. He gave details of his method of performing the latter operation.—Dr. WARD COUSINS thought inguinal superior to lumbar colotomy.—Mr. VINCENT JACKSON objected to the use of the term "inguinal colotomy," and thought it more correct to speak of it as "iliac colotomy." He had not yet either advised or performed proctectomy on account mainly of the distressing atresia. He preferred lumbar colotomy in acute obstruction; in other conditions he recommended "iliac colotomy."—Mr. BENNETT MAY had performed colotomy at an earlier stage since he had practised the inguinal operation. The inguinal operation was easier and more certain when the colon was empty, and in exhausted cases it caused less disturbance. He preferred the lumbar operation where there was much meteorism, and Madelung's operation when there was a prognosis of a considerable period of life. He thought moderate procidentia an advantage.—Mr. F. BOWREMAN JESSETT thought there were few cases that justified excision of the rectum. He was not satisfied with Allingham's operation, owing to the large amount of procidentia. He now practised complete division, closed the lower end with sutures, and dropped it back into the abdomen.—Mr. RUSHTON PARKER advocated excision. In one case he had divided the bowel as high as twelve inches from the anus. Access was obtained by incising backwards and upwards, removing the coccyx and lower vertebræ of the sacrum, and opening the peritoneum.—Mr. INGLIS PARSONS advocated the use of a powerful interrupted voltaic current, and related a case which was treated a year ago and remains well.—Professor TRENDELENBURG objected to the statements which had been made about German statistics, and expressed a strong preference for excision of the rectum in all cases where practicable. When the infiltration was not extensive the parts could be strapped without much cutting.—Mr. LAWFORD KNAGGS thought that in cases where the precise seat of obstruction had not been ascertained the left inguinal operation was preferable, seeing that the small intestine could be opened within a few inches of the ileo-cæcal valve.

Mr. MAYO ROBSON showed a patient on whom he had performed Cholecystenterostomy for a Biliary Fistula through which the whole of the bile had passed for fifteen months. The patient expressed herself as being in perfect health, only a scar remaining.

Mr. RUSHTON PARKER related a case of Cerebral Tumour attended with a puffy swelling of the scalp, removed by trephining from the right Rolandic area of a man aged thirty-eight. There had been severe headaches and stupidity, which eventually incapacitated him, followed by paralysis of the left arm and leg. Iodide of potassium was given without effect, and the operation was performed on Feb. 23rd, 1889, a large trephine being used. A tumour the size of a walnut was removed from the cerebral cortex. It looked at first like a firm sarcoma, but was now believed to be a gumma. Suppuration occurred in the brain, and a return of symptoms more serious than before. Opening up of the wound on Jan. 19th, removal of more brain, and the scraping out of suppurating tracks and packing the wound with antiseptic dressings, was followed by a cessation of bad symptoms and eventual sound recovery. The patient five months after operation was in excellent health, able to get about by himself and walk several miles.

At the meeting on Thursday, Aug. 15th, Mr. HENRY MORRIS read a paper on the Surgery of the Kidneys. The chief points discussed were as follows:—1. The various ways in which renal calculi are embedded in the kidney require special precautions whilst operating. 2. Tubercle of the kidney, as well as suppurating foci due to other causes, may give rise to the same tactile impressions as small calculi. 3. Tubercular disease of the prostate is a source of fallacy in diagnosing renal calculi. 4. Nephrectomy is of very doubtful value in advanced tubercular renal disease. 5. Lumbar nephrectomy is the proper treatment for advanced hydronephrosis and for large collections of fluid behind the peritoneum, the result of lacerated kidney. In these cases, nephrectomy, without previous incision and drainage, should be more frequently resorted to than has been the practice hitherto. 6. Nephrorraphy for movable kidney is often of great service. 7. The changes which the perinephritic tissues undergo under long-continued irritation sometimes render the search for the kidney very tedious and difficult.—The following took part in the discussion upon Mr. Morris's paper: Mr. Jessop, Mr. Bennett May, Dr. Newman, Mr. Lawson Tait, Mr. Bruce Clarke, Mr. Kendal Franks, Mr. Lawford Knaggs, and Dr. Imlach.

Mr. MAYO ROBSON gave an abstract of two hundred consecutive cases of Abdominal Section, with results. Of sixty-one cases of ovariotomy for large tumour he had had fifty-nine recoveries, with two deaths. In fourteen cases of operation for uterine myoma he had had twelve recoveries and two deaths; two cases of supra-pubic hysterectomy, with one recovery and one death; two cases of hepatotomy for hydatids, with recovery in each case; one case of nephrectomy, which terminated fatally; two cases of gastrostomy, with one recovery and one death; eleven cases of cholecystotomy, with sixteen recoveries and one death; one case of cholecystenterostomy, which recovered; thirteen cases of enterotomy for intestinal obstruction, with sixteen recoveries and three deaths; one case of enterectomy, which ended fatally; fourteen cases of opening and draining, with three deaths; thirty cases of herniotomy for strangulated hernia, with twenty-four recoveries and three deaths; twenty-nine operations for the radical cure of hernia, with twenty-eight recoveries and one death; and seven cases of exploratory operations, with four recoveries and three deaths (from malignant disease).

On Friday, Professor ALEX. FRASER (Dublin) described a "Method by which the Human Body, with all its essential details of Structure, has been made practically Transparent for Operative Surgical Purposes." First, as to the head and neck. The author said: "In a work, now approaching completion, which has cost me the leisure of the last four years, or,

Digitized by Google

rather, all left apart from onerous teaching duties, on the Morphology of the Mammalian Central Nervous System, especially that of Man, I was obliged to originate various methods, or rather, so far as this communication is concerned, to apply one in particular not much used by morphological anatomists in this country, and the capabilities of which, for biological and museum purposes, is but faintly appreciated; but that the illustrative anatomy of the future rests with it, and that not alone in a human direction, but in every domain of biological inquiry, is a conclusion which few having the love of those studies at heart, will seriously call in question. I mean the photographic method. The aim of this contribution, however, confines me to one of its applications—viz., the manner in which I have been able to represent the relations of the deep-seated parts to the skin, so that the surgeon can strike any portion of the outer surface of any organ, such as the brain, or of its internal structure, which he may desire to reach with an ease and certainty hitherto unattainable. To accomplish this, and to reproduce each division life size, I have adopted the ordinary way of apportioning the body into head and neck, thorax and abdomen, with proximal and distal portions of the upper and lower extremities. The only one of these divisions which I have thoroughly worked out is the head and neck, although in the young subjects the thoracic and abdominal viscera have in great measure been represented through the skin. I say nothing here of the method used in preserving the body with all its organs *in situ*; suffice it to say that it was only after many failures that I have been able to employ a method which leaves nothing to be desired. Neither need I say anything at present of the apparatus I use, further than that it has been made by the best makers from sketches sent by myself, and that it is more than large enough to reproduce the above-mentioned divisions of the body life size. In what manner, then, have I reproduced the head and neck so as to make the title of this communication justifiable? I have done it in two ways. These methods are shortly as follows:—1st. The head and neck can be looked at from four different points of view—lateral or from side to side, from vertex to base, from front to back, or from back to front, these two latter being much the same, though in an inverse order. I had to make, then, a series of views all of natural size in these different directions, so that, when the prints were made transparent and fitted in order one over the other, the entire structure, or as much of it as was my purpose to show, could be seen at a glance. I had made all these series, however, and had forgotten one thing, which made them useless for practical purposes, and that was. I did not show the diminution of the round of the head when projected on a plane surface, so that I had to begin again and arrange measuring tapes in a fixed manner on the head. By this means the diminution has been shown, while the surgeon can read off at a glance the relation of the internal structures to any particular inch or half-inch on the skin. The number of views I have made in each of the above-mentioned directions average from sixteen to eighteen, running in this way: first the skin, with its measurements; then the bone view; then dura mater, succeeded by pia mater; then external surface of brain and cord, followed by as many dissections of the brain as one's skill and knowledge can compass; and finally end at the skin again, if one so determines. This, then, is the first method, but it is not all. 2nd. In working through the head in the manner described above, I had laid aside a number of plates, and exposed each of them on three different views, the skin view being common to all, and found that I could with proper care take up three different views on a single plate. In this way, then, I have done away with the necessity under the first method of making the prints transparent, as the essentials of skin, bone, and brain views can be shown on one print, or any other combination, all taken direct from nature—such as skin, dura, and external surface of the brain, or skin, pia, and brain, or skin, outer surface of brain and central parts of brain, and so on indefinitely; this, then, is the second method. Words of mine in a communication like the present cannot express the full significance of a method such as this, which brings up the relations of the deep-seated parts to the external surface of the body with a fidelity which disregards the subjective leanings of the particular worker, and the many useful applications of which can only be discerned by the initiated.

At the same meeting, Mr. A. F. MCGILL opened a discussion upon the Treatment of Retention of Urine from Prostatic Enlargement. He advocated the following propositions—(1) That prostatic enlargements which give rise to urinary symptoms are intra-vesical, and not rectal. (2) That retention is caused by a valve-like action of the intra-vesical prostate, the urethral orifice being closed more or less completely by the contraction of the bladder on its contents. (3) That in many cases self-catheterisation is the only treatment required. (4) That when the catheter treatment fails, or is unavailable, more radical measures are necessary. (5) That this treatment, to be effectual, should (*a*) for a time thoroughly drain the bladder, and (*β*) permanently remove the cause of the obstruction. (6) That these two indications are best fulfilled by a supra-pubic rather than by a urethral or perineal operation. The supra-pubic operation is preferable (*a*) because it is more generally applicable, (*b*) because it can be performed with greater precision and completed with greater certainty, (*c*) because it ensures complete and most efficient drainage, (*d*) because it is equally safe. Of ten patients upon whom the speaker had operated eight had continued well, only one having required the passage of a catheter, and that only after excessive drinking. In one case, owing to the extreme hardness of the prostate, the operation was unsatisfactorily completed; in another there was temporary relief, with death at the end of ten months.—Mr. EDWARD ATKINSON said he had been the first to follow Mr. McGill's lead in performing supra-pubic prostatectomy. He had had five cases. Of these one had died, and the remaining four were well—had good control over the bladder, did not require to micturate more than six to ten times in the twenty-four hours, and were enjoying fair comfort.—Mr. REGINALD HARRISON congratulated Mr. McGill upon the practical value of his paper. He considered that his operation would occupy a permanent place in connexion with the surgery of the urinary organs, as it was based upon the recognition of those cases where the prostate not only obstructed micturition, but caused a vesical irritation far exceeding anything that either a stone or tumour is capable of creating. He referred briefly to some cases of advanced prostatic obstruction which he had treated by perineal prostatotomy, which he thought was specially applicable to those instances where obstruction was the prominent and most distressing symptom. He concluded his observations by a reference to the importance of the early treatment of prostatic enlargement by mechanical means.—Mr. BRUCE CLARKE stated that he had taken the greatest interest in the subject. The obstruction was due mainly to two causes: (1) the growth of the prostate into the urethra, and (2) into the bladder; and both of these must be relieved. He had had eleven prostatic cases under his care, in which some form of operation was required. So far his plan of treatment had been to make a perineal incision first, and examine the bladder; if necessary, incise the floor of the prostate; then one could ascertain exactly what needed to be done, and perform a supra-pubic operation afterwards, if necessary. He had done this in two cases with the best results.—Dr. WARD COUSINS said he had performed two operations for prostatic retention and calculus. Both cases were old men labouring under intense suffering. He enucleated some masses around the neck of the bladder, which proved to be cancerous. Both cases were for a time relieved. He thought Mr. McGill's operation would be the method practised in the future for cases in which catheterisation was impossible from pain and mechanical difficulty. The essential treatment consisted in the timely use of the catheter.—Mr. MACEWEN wished to say that after hearing Mr. McGill's paper, seeing his patients in the Leeds Infirmary and the specimens, he had upon this evidence become a convert to the supra-pubic removal of the prostate, as it removed the pathological cause of the difficulty; and he would put the operation in practice on the earliest suitable opportunity.—Mr. BENNETT MAY agreed that it is the intra-vesical growth which causes the obstruction and retention, and further, when retention is complete and permanent, that it is a collar enlargement; with partial retention, but great irritability, a pedunculated middle lobe. He believed that for drainage the supra-pubic is inferior to perineal cystotomy, but he regarded formal removal of any portion of the prostate by the perineal route as an impracticable proceeding in most cases. He thought Mr. McGill's operation should be done before the patient is much exhausted. In such cases median perineal drainage might be the more prudent course.—Mr. Jordan Lloyd, Professor Trendelenberg, and others also spoke, after which Mr. McGill replied.

Dr. OTTO E. KELLER read a paper upon Trephining in a case of Actinomycosis of the Brain.

Mr. W. ADAMS read a paper upon the Successful Treatment of cases of Congenital Displacement of the Hip-joint by Complete Recumbency, with Extension for two years.

OBSTETRIC MEDICINE.

On Thursday, Aug. 15th, Dr. HERMAN of London introduced a discussion on the Frequency, Diagnosis, and Treatment of Corporeal Endometritis. He first adverted to the difference of opinion as to the frequency of corporeal endometritis, which depended upon the fact that, while some accepted a diagnosis based on inference, others were not content with anything short of demonstration. The difficulty of demonstration arose from the impossibility of getting the secretion of the body of the uterus unmixed with secretion from other parts, and also from the imperfection of our knowledge as to the changes in the endometrium during the menstrual cycle, and also of those due to age. The limits of time obliged him to restrict his observations to the common forms, those occurring apart from pregnancy and the puerperal state and during menstrual life. The first referred to fungous endometritis, which was well known. This caused hæmorrhage, and was best treated by caustic and curette. We needed information as to its circumstances of origin; also as to whether it was ever a preliminary stage of cancer. Next as to gonorrhœal endometritis: this was no doubt a stage preliminary to salpingitis, but at present we had no knowledge of its symptoms. He then referred to endometritis occurring in the course of fevers, and its relation to subsequent abortions, placenta prævia, and menstrual disorders; then to endometritis from slight causes. This he believed always tended to recovery when the cause was removed without local treatment. Endometritis was described as producing slight local symptoms, but many reflex symptoms. He was not acquainted with such cases. He thought that the difficulty was to distinguish in such cases between symptoms due to the disease and those due to the patient. He did not think frequently-repeated applications to the endometrium were beneficial; one effectual cauterisation was much better. —Dr. BYERS (Belfast) said they must all thank Dr. Herman for his most suggestive paper. In reference to the use of caustics or the curette in the treatment, he preferred the latter (sharp curette), as it enabled one at a single operation to do what might require many applications of caustics. The object of curetting was to get rid of the diseased membrane at once. It should be done with antiseptic precautions. As to the gonorrhœal variety, he thought it often occurred in nulliparous women, and history was of great importance. He agreed with Dr. Herman in thinking that the application of remedies for chronic endometritis by means of probes was of little use; the caustic applied in this way did not reach the cavity of the uterus. He thought that cases of endometritis had a very direct bearing on obstetric practice, their presence often causing sterility and abortion.—Dr. ROUTH spoke in favour of injections into the uterus.—Dr. GRAILY HEWITT regarded congestion of the uterus as of first importance in these cases, and he looked upon flexions as causing endometritis through this congestion.—Mr. TEALE (Leeds) thought that dilatation of the os internum was of great importance as a factor leading to good results in treatment, and was a safeguard in getting the remedies applied.—Dr. BRAITHWAITE (Leeds) thought there were in unmarried women cases of dysmenorrhœa with endometritis and simple cases of dysmenorrhœa; in the former good results followed dilatation and curetting, but he thought that dilatation up to No. 7 or 8 (Hegar) was enough. He believed curetting was good in chronic cases. He dilated up to No. 7 or 8 (Hegar), then applied the liquid carbolic, or a solution made of equal parts by weight of iodide of potash and spirits of wine.—Dr. H. JONES thought cases varied according to the stages. He believed in dilatation and curetting with the blunt curette, and to prevent lapsing discharge he applied iodoform pessaries to the interior of the uterus.—Dr. DUKE and Dr. MORE MADDEN advocated the method of dilatation and the use of the sharp curette.—Dr. HORROCKS said he had only seen one case of tubercular endometritis, and he spoke of the importance of alcohol as a cause of endometritis, a symptom of which was frequent hæmorrhage.—Dr. BELL and Dr. MURDOCH CAMERON (Glasgow), and Dr. WALLACE spoke.—In summing up the discussion, Dr. CULLINGWORTH (the President) said they were all agreed that corporeal endometritis was a reality, and that curetting was the best plan of treatment, combined with dilatation and done with antiseptic precautions. He thought that in thus dealing with these cases in a vigorous and effective way they had tended to raise the position of gynæcology, the former methods being slow and often failing.—Dr. HERMAN replied.

The following papers were then read:—On Cardiac Insufficiency in its relation to Abortion, by Dr. Handfield Jones; Cæsarean Section, with notes of a second successful case, by Dr. Murdoch Cameron (Glasgow); Concealed or Ante-partem Hæmorrhage, by Dr. Arthur Roberts.

On Friday the whole time of this Section was taken up in an interesting discussion on the bearing of Electricity in Gynæcology. Dr. PLAYFAIR was unable to be present, but in his absence Mr. WHEELHOUSE read his paper—an Estimate of the Value of Electricity in Gynæcology,—which was based on the results of two years' work. In his communication, Dr. Playfair said the objectors to the electrical treatment in gynæcology had no practical evidence to give, and, if theoretical objections were of weight, then we should never have had an ovariotomy or any anæsthesia. Many of those who had tried this method had done so in an imperfect way, and often used imperfect instruments, and it was incumbent on them all to follow strictly the rules laid down by Apostoli. In non-hæmorrhagic cases, Dr. Playfair's experience was small, but in instances of tumours impacted in the pelvis he had good results, and he thought in such cases hysterectomy was not legitimate till electricity had been tried and had failed. It was well known that fibroid tumours sometimes got gradually smaller of themselves, and it might be that by electricity we started by art a process which gradually went on till the tumour disappeared or got less in size. The application of the positive current to the uterine cavity in hæmorrhagic cases was of great value, and here Dr. Playfair thought a very decided advance had been made; in several cases, he said, it had prevented the removal of the uterine appendages, or hysterectomy, and it had succeeded when other hæmostatics had failed. Just as surgeons, before amputating the thigh for disease of the knee-joint, would try simpler methods, so, he thought, electricity should be employed before having recourse to surgical interference in cases of fibroid tumours. He had found the electrical treatment good in membranous dysmenorrhœa and in cases of obstinate chronic uterine catarrh. Finally, he drew the following conclusions:—1. The continuous current is capable of effecting much good in certain selected cases otherwise little amenable to treatment; and its introduction is, therefore, a distinct gain to gynæcology. 2. It is an agent of considerable power, and therefore, if rashly and injudiciously used, it is also capable of doing much harm. 3. It involves the cost of a costly plant, and it is troublesome and tedious to work. 4. Since the proper selection of cases requires, moreover, much special knowledge and great care in the application of the remedy, it is never likely to come into very general use.—Dr. CUTTER (New York) gave details of his eighteen years' work in the United States in the treatment of uterine fibroids by galvanism. He had arrested 50 per cent., cured 22 per cent., and his mortality had been 8 per cent.—Mr. LAWSON TAIT (Birmingham) said that since 1880 he had removed the uterine appendages for uterine myoma in 262 cases, with a mortality of 1·23 per cent. He said Dr. Playfair's paper was full of scattered details; what he asked for was a tabulated statement of cases treated by electricity, the total number of cases, those cured, and those in which there had been death. Until this was done no mere statement was of any use. When the electricians took a tumour, say on the leg or arm, outside the body, whose size they could estimate exactly, and caused it to disappear, he would believe in the efficacy of this method. They had two methods of treating myomata, the surgical and the electrical. Speaking of the mortality after abdominal operations, Mr. Tait said there were intrinsic and extrinsic mortality influences. The former were due to the surgeon himself, such as failing to tie a vessel or leaving a sponge in the abdominal cavity. His results, which he to-day presented to them—a mortality of 1·23,—showed that the intrinsic causes had disappeared. The extrinsic mortality influences were independent of the operation, and one of the most important of these in myomata was delay. Now, if the electrical treatment did no good in a case, it did further harm by the time lost in

Digitized by Google

the treatment. It was said removal of the uterine appendages unsexed patients; they would have no more children. His reply was that those with these tumours were often sterile; and, further, did the electrical treatment cure them so that they afterwards became mothers? Again, it was argued as an objection to removal of the appendages that it caused disappearance of the sexual appetite. This he denied; and, even if it was true, it was better for humanity. As to Dr. Cutter's statistics, his mortality was 8 per cent., the same, Mr. Tait said, as hystèrectomy, and his cures were 22 per cent.; while in hysterectomy the cures were 91 to 99 per cent.—Dr. PARSONS hoped Dr. Keith would furnish them with his results.—Dr. BELL (Glasgow) welcomed any treatment which would do away with surgical interference.—Dr. GRAILY HEWITT said his experience in the use of electricity was not fortunate.—Dr. BRAITHWAITE (Leeds) had tried electricity in thirteen cases, and said it had advantages, and should be applied to certain cases; but it was tedious and very expensive. On the other hand, the risks of oöphorectomy were very slight. If the fibroid was in the posterior wall of the uterus or in the fundus, or if it was multiple, he would remove the appendages. He would try electricity if it was in the anterior wall.—Dr. MORE MADDEN (Dublin) spoke in favour of electricity, Dr. IMLACH (Liverpool) against.—Dr. HORROCKS (London) said they had found no good results follow the use of the electrical method at Guy's Hospital. He thought they should recollect that the history of fibroid tumours indicated to them that in the vast majority of cases patients with them did not die even if untreated.—Several others having spoken, a very interesting discussion was brought to a close by the President, Dr. Cullingworth, to whom a very hearty vote of thanks was accorded for the thoroughly business-like way in which he had presided over the Section of Obstetrics and Gynæcology.

PATHOLOGY AND PHYSIOLOGY.

In this section Dr. COATS (Glasgow) gave a most interesting opening address, in which he spoke of the susceptibility of races, individuals, and organs to various forms of disease, laying special stress upon the facts brought out in connexion with heredity, with acquired susceptibility, and pointing out how these might vary under different conditions of nutrition and position. It is a subject specially studied by Dr. Coats, and will no doubt appear *in extenso*.—Professor GAIRDNER (Glasgow) did not think Dr. Coats had cleared up all the difficulties; that was impossible, but he had put into clear and definite form many very difficult questions. It frequently happened that we acquired a man's terminology without grasping his ideas, and when that was the case it was no wonder that we misquoted and led others to misunderstand. It had often struck him that John Hunter was an example of a man who was not able to make himself understood. He was a man not learned in the schools, and he had to invent his own terminology. It was a positive ordeal for him to give a lecture; and so much did he feel this that he was often compelled to have recourse to opium to enable him to face his students. All his writings bore the impress of a want of power to express all he had in his mind, and all he wished to say. So much was this the case that Professor Gairdner had at one time been almost tempted to believe that Hunter was not the great man he was always represented to be. When, however, he came to see his museum and his wonderful collections of all kinds, he was fully impressed with the power and the greatness of the man. His phrases, however, were not even clear to himself, and still less so were they to other people. It was a case of tyranny and coercion, as in all cases he was afraid the theoretic bias misled where definitions and theories were concerned. For instance, what John Hunter called coagulable lymph was in the earlier history of the subject of pathology spoken of as exudation. The term was frequently used, but usually with very different meanings. This exudation was looked upon as a kind of sweating out of blood-vessels, the material differing in different cases, or afterwards becoming much altered, and giving rise to various forms of new growth, organised or degenerating. Virchow went a step further, and pointed out that all cells, in diseased processes as in healthy ones, were derived from pre-existing cells, and that with multiplication came differentiation. Why this was the case was not determined. The process of disease had now been traced back a step further, and it was known that specific micro-organisms had a specific action on certain groups of cells, which, in consequence, underwent certain series of changes. Speaking of constitution and habit, it was often difficult to determine how far these were local, how far they were general, and how far hereditary. What was more local than a habit of a particular part of an organ? He might take as an example that mentioned by Darwin, where a man was in the habit of allowing his thumb to rest on the bridge of his nose when he was asleep. This habit was continued through three generations of his descendants, and in one case, at any rate, it could not be due to imitation, as the father died when his successor with the same habit was in the cradle.

Dr. CHURTON gave a paper on Indicanuria, in which he stated that he had found indican in cases of typhoid and other fevers, and in twelve cases of the former disease he had found it in all stages. In cases of fæcal toxæmia, however, he had found the reaction with hydrochloric acid and chlorinated soda especially well marked. This had happened several times, especially where there was intestinal obstruction, and loading of the small intestine as well as the large. He had been led to ask the question whether some of those cases of so-called apyrexial typhoid were not simply cases of fæcal toxæmia. It was the general opinion that indol, skatol, &c., were imperfectly transformed into urea, and passed out as indican in the urine.—Mr. HENDERSON (Jamaica) asked if chlorate of potash might not be used instead of chlorinated soda.—Dr. CHURTON thought that it might, and the process of the reaction was simply the oxidation of indican into indigo, by which means the characteristic indigo colour was obtained.—Dr. JACOBS thought that there were cases of typhoid in which pyrexia was absent, giving, as an example, the case of the soldiers before Paris, who in their extremely emaciated condition had no pyrexia. This might be because their temperature was in the first instance subnormal, so that on the onset of the disease the normal was a high temperature for the individual affected.—Dr. COATS was not very sure about the origin of indican, and thought that, in some cases at any rate, the peculiar reaction was due to the presence of extraneous matter—such, for instance, as carbolic acid.—Dr. CHURTON, in reply, cited a series of experiments from which he has been able to determine that carbolic acid was not the cause of the reaction. Indican might be formed from indol in the epithelial cells of the kidney, and might be due to the absorption of fæcal products.

Dr. MOTT read a paper on the Pathology of Cardiac Failure. He insisted that the whole circulatory system must be taken into account in considering this important subject, not only in the cardio-vascular system, but in the contained blood also. In all cases of failure of the circulation there was some alteration in the nutrition of the cardio-vascular system. The heart itself, which acted as the force-pump, was in every case disorganised. In myocarditis, fatty degeneration, and some other conditions there was usually coronary obstruction. This was very important, as in forty-nine out of fifty cases examined there was organic disease of the myocardium. It was necessary to examine the coronary arteries, not only at their openings into the coronary sinuses, but also for some distance from the mouth, as it was frequently found that there was constriction at as much as one inch from this point. In partial obstruction the degeneration was not usually fatty, but was often merely a part of a widespread degenerative process associated with chronic inflammation, affecting the cardio-vascular system, especially the heart and kidneys. In these cases the termination was not sudden, and was quite different from those cases in which there was sudden failure from imperfect filling of the cerebral and coronary vessels, as when the patient sat up suddenly. In most of the cases of complete obstruction of a principal branch of one of the main trunks, with partial occlusion of the other, there had been a syphilitic history. Of five such cases four had died suddenly from syncope due to fatty degeneration of the myocardium. Dr. Mott then discussed the conditions met with in chronic alcoholism in which there was no affection of the coronary arteries, but in which fatty degeneration had been followed by sudden and fatal syncope. In cases of fatty degeneration he pointed out how the arrangement of the muscles led to imperfect action of the valves—the musculi papillares, in which the process is best seen, being the continuation of the figure-of-8 bundles of muscular fibres in the walls of the cavities of the heart. This explanation might be readily adapted to Mr.

Digitized by Google

Williams's theory of "delirium cordis." In no case was it sufficient to make a diagnosis without the aid of the microscope, and he recommended that osmic acid or Pal's modification of Wright's method should always be used in order to determine the amount and distribution of fatty degeration in the myocardium. Fatty degeneration alone did not produce angina pectoris, as was evidenced from those cases of pernicious anæmia in which the fatty degeneration was well marked, but where there was no angina at any stage of the disease. A description of acute and chronic myocarditis was given, and it was pointed out that the former was invariably associated with acute fatal pericarditis. At the close of the paper some beautiful photo-micrographs of various forms of disease of the heart and bloodvessels were projected on to a screen. This demonstration was most instructive, and was greatly applauded by the members present.—Dr. POPE asked if Dr. Mott had directed his attention to the condition of the coronary sinus in the cases he had examined.—Dr. HENDERSON (Jamaica) thought that Dr. Mott had passed somewhat lightly over the more acute changes with which they in the tropics are familiar—as in cases of malaria, yellow fever, &c. In these cases it was a rule with them that the tendency to heart failure was so great that the patient must be kept absolutely quiet, even though his surroundings at the time he was struck down were not all that could be desired. In melanuric fever they frequently found coagulation necrosis of the myocardium of the left ventricle, and in such cases they observed that the heart stopped in diastole. In hæmorrhagic cases he had met with small thrombi in the coronary arteries, and in these cases they always found subdurous petechiæ. Although this was the case, embolism was rare in such conditions.—Dr. CROOKE (Birmingham) said that he quite agreed with Dr. Mott as to the absence of anginal symptoms in cases of fatty degeneration. He had never been able to determine that there was any change in the ganglia associated with either heart or bloodvessels, but he could not say how far this was his fault.—Dr. WARDROP GRIFFITH agreed that the distribution of atheroma was not what was usually described; he quite thought that it was a law unto itself. He exhibited an infected specimen of the heart, from which it was evident that there was free anastomoses between the coronary arteries of the two sides, probably through the capillaries, through which ordinary wax injection could not pass.—Dr. COATS said that, from his experience, the coronary artery was frequently obliterated on one side and partially closed on the other in a considerable number of cases; perhaps in the course of his work he came across three or four in a year. He observed that it was not until quite recently that it was known that the coronary arteries were diseased in such a large proportion of cases. He referred to the work done by his assistant, Dr. Lindsay Steven, and Dr. Newman, the former of whom had found that there was a communication between the two coronary arteries, not by capillaries only, but also by means of small arterioles. There were some points concerning which he could not agree with Dr. Mott: first, as to the causation of angina; and, second, as to the frequency of syphilitic atheroma and aneurysm. In Glasgow they had a large number of cases of both atheroma and aneurysm, but he was glad to say that syphilis was comparatively rare. It of course happened that the two conditions were found together, but there were no statistical facts to establish any definite relation between the two.—Dr. MOTT, in reply, said that the damming back of the blood in the coronary sinuses had first been pointed out by Sir Wm. Jenner, and that Dr. Mitchell Bruce had more recently referred to the same condition. As regarded the acute changes mentioned by Dr. Henderson, he had seen a number of cases of typhus fever in which there was cardiac failure, and a similar series of changes in connexion with surgical kidney, diphtheria, and similar diseases. Angina was certainly associated with coronary sclerosis, but he must admit that degeneration of the nerves of the heart was very difficult to demonstrate, and though he had examined, he might say, thousands of sections, he had never been able to satisfy himself on the matter, more especially as there was, so far as he was aware, no standard by which he might go in making his comparative observations. In one case at least, however, inflammation around the aorta must have affected the coronary plexus. He was satisfied that in the disease one coronary artery was quite sufficient to nourish the heart. In three out of the four cases of syphilis scars were actually found, and in one patient, aged twenty-nine, the kidney was not affected. He was quite aware, however, that much was attributed to syphilis, especially when there were no accurate data on which to work.

Dr. POPE read a paper on a case of Thrombosis of the Vertebral Artery, with Pressure on the Glosso-pharyngeal Nerve and Unilateral Loss of Taste. It was found on post-mortem examination that the left vertebral artery was distended by a clot, so that there was a fusiform enlargement. The brain and heart were both normal. The dilated artery pressed on the glosso-pharyngeal and also on the roots of the pneumogastric nerve. This gave rise to the symptoms mentioned above. The patient could not swallow. There was partial paralysis of one side, but no loss of speech and no urinary troubles. The left pupil was smaller than the right and insensible to light, and the left side of the soft palate was higher than the right. There was some pain and numbness, which might be due to the interference with the blood-supply to the descending tract on that side. The tip of the tongue was not affected, nor was the chorda tympani. The evidence of pressure on the glosso-pharyngeal was the loss of taste of one side of the tongue.

Dr. CROOKE (Birmingham) read a paper on the Histology of Bright's Disease, or rather, as he said, described a series of specimens which were under microscopes in the demonstration room. It was suggested that Friday should be devoted, partly at any rate, to the discussion of these specimens. This was agreed to unanimously; and after Dr. Crooke had given a lantern demonstration the meeting adjourned to examine the specimens.

At the meeting on Thursday, Dr. T. J. MACLAGAN forwarded a paper to introduce the subject of Fever to the Section. This was read by the Secretary, Dr. E. H. Jacob. Dr. Maclagan maintained that in all cases it was important to bear in mind both the metabolic and the neurotic phases of the causation of fever. In cases of fever in cerebral affections there must undoubtedly be impaired inhibition, not as a passive agent merely, but as an active condition. The neurotic and the metabolic causes acted in different spheres, but both were essential, though the thermotaxic derangement might in some case be more prominent than the thermogenic disturbance. In the case of specific fevers he considered that the organismal theory was the only one that would explain all facts, and in connexion with this he thought it should be pointed out that, although the production of the poison went on continuously, the temperature did not rise beyond a certain point, and from this he should argue that the process was not entirely nervous. The changes which were associated with the taking up of nitrogen and water were in some way connected with the production of heat.—Dr. BROADBENT thought that we could not look upon the two theories as antagonistic to one another; whatever be the mode in which the fever was determined, it must be conceded that it came ultimately from metabolism. He considered that the theory that heat resulted from the taking up of nitrogen and water by micro-organisms was difficult to understand, as it was, he should say, a process of construction in which heat was used up, rather than one of metabolism, in which heat was set free.—Dr. SIMS WOODHEAD agreed with Dr. Broadbent that the taking up of the nitrogen and water could not account for the increase of heat. He thought, however, that the increase of temperature, in so far as it was a real thermogenesis, might be brought about by stimulation of the tissues by the products of micro-organisms, and that F. Darwin's researches on the effect of carbonate of ammonia on the protoplasm of cells threw some light on the subject under discussion. Certain tissues would react much more energetically and continuously under the inflence of stimuli than others, and the period of depression appeared to him to come on at a much earlier stage in the nerve centres than in the other organs and tissues. This might account for the altered thermotaxic arrangement as well as for the altered thermogenic arrangement.—Dr. HANDFORD said that sufficient attention had not been directed to the fact that the thermometer did not indicate the rise of heat. To be perfectly accurate it was necessary to use a calorimeter, an instrument very difficult to use and very expensive to make. In inflammatory processes there might be a rise in temperature without any extra production of heat, so that the increased surface temperature might be due to rapid elimination by surface radiation, rather than to increased production.—Dr. COATS was certainly disappointed that more points had not been raised in the discussion, for whatever might be the opinion of previous speakers, Dr. MacAlister's theory, as advanced in his recent lectures, was by no means

Digitized by Google

convincing in many respects—as, for instance, in connexion with the functions of muscle as a contractile organ and as a heat producer. He might point out that even in the cold stage of fever there was an increased production of heat, and he should of course agree that the rapid rise afterwards had something to do with the impaired discharge of heat.—Drs. BROADBENT and WM. HUNTER both expressed the opinion that Dr. MacAlister contended that, although both processes were usually at work, there might be great fever without increased metabolism, and the reverse, and that what took place could not always be measured by means of the thermometer. The thermogenic and thermotaxic mechanisms both played important, but by no means constant, parts (relatively) in the process of fever.

Dr. HANDFORD read a paper on the Visceral Lesions occurring in Enteric Fever. He had observed and carefully studied sixteen cases in his own practice during the last four years, and he had come to the conclusion that the chief factors in the production of these lesions were high temperature, septic organisms, and typhoid organisms (if such were present, of which he had not yet convinced himself). He wished specially to point out that in all his cases the lesion described pointed rather to what had been called mixed infection. He had noted that organisms passing through certain individuals appeared to have had their virulence increased, whilst in other cases it was diminished, this being the case especially in cases of what might be called diarrhœa resulting from the inhalation or ingestion of micro-organisms. He then described in detail the changes in the stomach and intestines, including minute infiltrations, small ulcers, &c. In the lung he met with a special form of pneumonia which, though lobular in its distribution, was croupous or exudative in character. There were also marked interstitial changes. This form of lesion appeared to be rapidly followed by death, and it seemed to be due to actual septic infection. In the heart there was degeneration of the muscular fibres associated with more or less interstitial change. In the liver he had frequently demonstrated the presence of an interlobular infiltration of small, round cells, which eventually became converted into fibrous tissue. He would explain, and to his mind did so satisfactorily, those cases of non-alcoholic cirrhosis met with especially in children. There were usually found also cloudy swelling and fatty degeneration of the liver cells, and in some cases these changes were due more or less directly to the presence of some septic organisms, although there might be no abscess formation. The most marked changes in the kidney were interstitial and glomerulo nephritis.—Dr. CROOKE agreed in the main with Dr. Handford. He (Dr. Crooke) had pointed out that similar interstitial changes occurred in the liver in many cases of scarlatina. He had also described similar conditions to those mentioned by Dr. Handford as occurring in the kidney.—Dr. WOODHEAD was very glad that Dr. Handford had insisted so strongly on the fact that in enteric fever there was frequently a mixed infection. He had observed the same thing in connexion with this fever, and also in cases of scarlatina and diphtheria. He agreed that the lesions should be divided into two groups as soon as such division was possible: first, those essential to the disease; and, second, those the result of septic infection, or perhaps in certain cases of septic poisoning.—Dr. MOTT thought, from the description given and the drawings made by Dr. Handford, that the conditions met with in the heart might be summed up as septic myocarditis. He thought that syncope would play an important part in the death of the patient, and that fatty degeneration must have been present in many of the cases mentioned. He described Mr. Lingard's typhoid lesions of the liver, in some of which were present the bacilli said to be characteristic of typhoid fever.—Dr. JACOB considered that there was in many cases mixed infection; but he also thought that many of the immediate effects of bad smells were due to the action of bad gases, and not to micro-organisms at all. There might be gaseous blood-poisoning quite apart from micro-organisms. He pointed out that one epidemic of a specific fever differed from another according to the class of person in whom the poison had been evoked, and from whom it was disseminated. It was quite possible that, in course of time, we should desire to choose the individual from whom we should wish to take our dose of poison. This was quite within the range of Pasteur's system.—Dr. COATS spoke of the mode or path of infection; it was certainly not always by the lung, and was far more probably through the blood. Drs. Handford and Crooke had discriminated between the modes in which the lesions were produced in typhoid fever and scarlatina, and they had agreed that some of the lesions were very similar in the two diseases. It came to be a question whether we were able or not to discriminate the specific lesions from the general. It should be remembered that septic infection was a very different thing from septic poisoning. In the case of enteric fever, as in many other diseases, there were four possibilities to be considered in regard to the mode of infection &c.: (1) that there might be a specific microbe in the blood which could be carried to and deposited in various organs; (2) that a specific animal alkaloid might be distributed in the same manner; (3) that there might be a local lesion formed which opened up the road for the invasion by septic organisms, and (4) a similar lesion opening up the way for septic poison. It was necessary to consider how, in connexion with the lesions in the lungs, the diseased matter had got there. Was it possible that the bronchus was the centre of infection?—Dr. HANDFORD, in reply, said that he had been interested in the study of these cases, more especially from the clinical side, and had studied their pathology in order to gain light on certain clinical symptoms.

Mr. ROGER WILLIAMS read a paper on Evolution in Neoplastic Processes, in which he stated briefly the views he held on the genesis of neoplasms. He reviewed the position taken up by Virchow and others, and reverted to Goodsir's theory that every cell may be the centre of growth, and that it has the potentialities of an individual. It could under certain conditions give rise to the growth of an individual, and under other conditions to the growth of a tumour. He scouted the micro-organismal theory of tumours entirely, and looked upon tumours as lowly organised potential individuals.—Dr. MOTT asked Mr. Williams if he accepted any or part of Cohnheim's theory.—Dr. WOODHEAD thought that Mr. Williams should make some distinction between sarcomas and cancers in accepting or rejecting the micro-organismal theory of their causation. For his part, he considered that many of the so-called sarcoma would ultimately be relegated to the category of specific infective new formations, whilst cancers, as their President had told them in his opening address, were associated with lowered conditions of the tissue and with irritation of epithelial surfaces. He believed that this irritation, not only of the epithelial but also of the deeper tissues, might be the result of the action of various irritants, and of course amongst these micro-organisms might be reckoned. Micro-organisms would not account for the appearance of similar epithelium in distant parts, and it was on this ground that he ventured to differ from some great authorities on the subject.—Dr. COATS said that a new formation must be looked upon as a piece of tissue growing independently; but the statement of this fact could not be said to bring us any nearer the point at which we were aiming, and he could not see how Mr. Williams had brought us much light, though his paper was eminently suggestive. He quite agreed with some of the speakers that some of the sarcomas must be transferred to the group known as infective granulomata, and in the work on which he was at present engaged he had given effect to this recognition of the fact. He must dissent from the statement that cancers were lowly organised. Very frequently they were composed of a highly developed type of tissue, and he had seen one in the bone of the skull which had the mature structure of well-formed thyroid gland.—Mr. WILLIAMS, in reply, remarked that it was much easier to criticise a theory than to form one. He might say that throughout his work he had tried to bring to bear on his subject the latest developments of biological research, and to bring before them a statement of facts based upon our present biological knowledge.

Dr. WOODHEAD gave a short account of some experiments made by Inoculation into Rabbits of Material from Tuberculous Cattle, in which suppurative peritonitis and pleurisy had been developed. In all the animals in which this had occurred the glands had been previously affected by tubercle.—Dr. MOTT had noted a number of similar cases where he had used guinea-pigs for his experiments.

Dr. WARDROP GRIFFITH gave a demonstration and note on Portal Obstruction and Compensatory Venous Enlargement in Cirrhosis of the Liver. The veins of the round ligament and of the anterior abdominal wall were greatly enlarged. He agreed with Dr. Drummond's explanation of the phenomena observed It this case there was slight

Digitized by Google

hæmatemesis, which, he should observe, did not always act as a safety valve. In addition to the communications already mentioned, there were, of course, those of the veins around the œsophagus, rectum, &c.

Dr. E. H. JACOB gave a lantern demonstration of the Visceral Lesions of Syphilis; and Dr. MOTT exhibited some lantern slides and microscopic specimens of similar lesions.

At the meeting on Friday, in opening the discussion on the Histology of Bright's Disease, Dr. CROOKE said that he based his observations on the examination of sixty cases of acute nephritis occurring in the course of other diseases. Dealing with the kidney in its normal condition, he said it was easy to observe the kidney in any stage taken from the animal, but not so in the case of man, as a man must have died suddenly from accident, and even then he might recently have been drinking a quantity of fluid. He then dealt with the symptoms of healthy and diseased kidneys. True parenchymatous nephritis he considered to be an ideal disease, and he placed more reliance on Cohnheim's researches, and gave cases of his own supporting Cohnheim's results and statements. He coincided with the view set forth in Dr. Saundby's work that the lardaceous changes in Bright's disease were not sufficient in extent or importance to be regarded as primary; that nephritis was also secondary, and that both were concomitant morbid phenomena, traceable to the same cause. He had only seen one case where the history was quite clear, and that was a lardaceous case. In another case, where there was no history of a previous illness, the lardaceous changes were also well marked, the kidneys being of the large white type. The intestinal changes were never present by themselves, nor were the epithelial changes ever met with alone. There was simply a different proportion in different diseases and in different stages of the same disease.—Dr. DRESCHFELD quite agreed that in Bright's disease the whole of the changes were the result, direct or indirect, of an inflammatory process, and the differences were those of degree and position rather than of kind. In the granular contracted kidney we had chronic interstitial changes, whilst in the forms of acute Bright's disease the parenchymatous changes were more prominent. So far as he could find, there were no changes in the muscle cells of the middle coat. He contended that it was now necessary to distinguish the different positions in which we got the various changes in the glomeruli. In acute scarlatinal nephritis the true glomerulo-nephritis was met with, whilst in the chronic interstitial forms a pericapsular glomerulo-nephritis was met with. He was glad that Dr. Crooke had mentioned that there was vacuolation in the epithelial cells in the chronic as well as in the acute forms. Of course there were cardio-vascular changes wherever there was increased blood-pressure, as in subacute nephritis.—Dr. RUSSELL believed that glomerulo-nephritis was much more commonly found in non-scarlatinal cases than was generally supposed, though it was usually met with in specific infective fevers. He had certainly found that there was an increase in the amount of interstitial tissue in most chronic cases, but he had observed a case now and again in which this was not the case. The true cirrhotic kidney (small granular) might be the termination of post-scarlatinal cases, but he thought that a great number of the chronic cases of kidney disease took their origin in vascular changes in the organ.—Dr. CHURTON, as a result of his experience, had come to the conclusion that the conditions of the kidney were not the cause of hypertrophy of the heart. He frequently came across cases of granular contracted kidney in which there was no hypertrophy of the heart, and of course many cases of cardiac hypertrophy in which there was no kidney disease, or, at any rate, no granular contracted kidney. He looked upon disease of the vessels as the common cause of both conditions.—Dr. WOODHEAD had not yet been able to satisfy himself that there was ever any sharp line of demarcation between the interstitial and the parenchymatous forms of Bright's disease. One or other might be the predominating feature, but, so far as his experience went, they were always associated conditions. As to glomerulo-nephritis, he certainly thought that the true form occurred in those cases in which the epithelial changes were most marked—acute parenchymatous nephritis,—and that the pericapsular changes were really part of the interstitial or comparatively chronic processes. He was at one with those pathologists who objected to the term "large white kidney." In the first place, as Professor Hamilton had pointed out, it was not white; and, in the second place, we had a large pale organ in so many different forms of diseased kidney that, unless everyone agreed as to the exact meaning of the term, there might be, as frequently happened, great confusion. It was not desirable that the acute parenchymatous form, the subacute interstitial form, the waxy, and the fatty kidney should all have the same term applied to them, when each might be equally well denoted by more accurate and distinctive terms.—Dr. COATS said that, although he had long been trying to get away from the purely parenchymatous form of nephritis, he had been compelled, he might say almost against his will, to come back to it. He was decidedly of the opinion that in scarlatina there were two poisons to be reckoned with, the specific and aseptic, this latter coming in to play its part especially in the later stages of the disease. In the first case there was glomerulo-nephritis, associated with parenchymatous nephritis, in which there was a collection of shed and proliferated epithelial cells within the capsule and the convoluted tubules. The septic irritant, which was often a concomitant, brought about more widely distributed changes, which affected especially the vascular system. He objected to the term glomerulitis, as it left out of count the fact that it was part only of a nephritic process. As regarded the term "large white kidney," he could not agree with one of the speakers, as he thought that, with proper limitations, it was a useful term, referring as it did to a definite stage in the course of the disease. He had hoped to hear more about arterio-sclerosis, as he had very small experience of the condition, gout being a comparatively rare disease in Scotland, but he thought that the chronic interstitial form of Bright's disease in gout was quite a local disease.—Dr. CROOKE was pleased to think that it was considered he had made out a strong case for the unity of type in the various forms of Bright's disease, which he thought he had done if a few puzzling and very exceptional cases were left out of consideration for the time. He looked upon every form as merely a transitional stage in the course of the disease. The kidney was like other organs in the fact that vascular changes must lead to other important structural alterations. Increased pressure would give rise to enlargement of the capillary loops, and, as was often found, they had granular material and even blood-corpuscles between the loops or between the tuft and the capsule. He was glad to think that he had brought forward points that had admitted of such general discussion.

Dr. DRUMMOND gave the history of a case of Acute Lead Poisoning that had recently come under his observation. There was œdema of the eyelids, but no other dropsy, double optic neuritis, marked constipation, lethargy, and headache. The blue lead line on the gums was well seen. The patient had convulsions, followed by coma, then a rapid rise of temperature from subnormal to 104°F., and death. The pecularity of the case in connexion with the cerebral symptoms, which were usually absent, was the presence of a very considerable amount (a couple of grains estimated as pure lead) of lead in the brain. He remarked that medical men seldom had the opportunity of making post-mortem examinations in cases of death from lead poisoning, as the medical officers of lead factories would not allow their patients to go into the infirmary, as an inquest was then necessary in case of death.—Dr MACKENZIE (Burnley) was doubtful whether this could be looked upon as a case of acute lead poisoning from what he had heard of the history.—Dr. CHURTON said that in his experience in and around Leeds lead did not affect the brain at all. It was difficult to determine in these cases whether the patient died of syncope or from respiratory failure.—Dr. CROOKE said that they had numerous cases of chronic lead poisoning in Birmingham, and perhaps he ought to have mentioned this fact in connexion with his observations on the kidney. In cases of lead poisoning he had found acute interstitial myositis, which gradually became chronic in both the voluntary muscles and the heart.

Dr. WOODHEAD gave a short note on Ulceration of the Vermiform Appendix, leading to Suppurative Peritonitis. He found that the ulceration was localised, that the point of perforation was usually some little distance from the cæcum, and that the tube between these points was healthy; so that it would be an easy matter to obtain a perfectly healthy portion that could be ligatured above the point of perforation. This was important, as he quite agreed with recent surgical writers that many cases of peritonitis said to be due to obstruction of the bowel were really cases of peritonitis due to ulceration of the vermiform

Digitized by Google

appendix. In all the cases he had examined he had found hard concretions composed of mucus (sometimes traces of hardened fæces) and particles of phosphate and carbonate of lime, which were separated by the epithelial cells of the simple cysts in the mucous membrane lining the appendix. At the point of ulceration there was found a regular coagulation-necrosis layer, beneath which the vessels were greatly distended, and it was evident that the breaking down was due to some localised injury. The concretions themselves, unless very large, were sufficient to cause only localised catarrh; but if the cæcum became much distended, or if there was a sudden strain of the muscles or blow over the hard concretion, a localised necrosis resulted, and eventually ulceration and perforation. He exhibited microscopical preparations of the various parts of the appendix described.—Dr. JACOB was doubtful as to the agency of these concretions in the production of ulceration of the vermiform appendix.—Dr. WARDROP GRIFFITH related the facts of a case in which there were two concretions, one of which was in the abscess, surrounding the perforated appendix, and the other fitting the floor of the ulcer exactly. He considered, of course, that the effects of ulceration varied according to the relation of the peritoneum, and it should always be remembered that the appendix itself was completely surrounded by peritoneum.—Dr. COATS had been greatly interested, as he had been studying the relations of these perityphlitic abscesses to the peritoneum. He mentioned a case in which the pus had passed from the right side to the left across the abdomen, and then had made its way to the under surface of the diaphragm, this being followed by an attack of acute pleurisy on the left side. Many of these cases recovered, but it was probable that the appendix was not actually perforated.

Dr. JACOB exhibited for Dr. A. W. Sinclair specimens of Distoma Crassum taken from a gentleman suffering from beri-beri. In the same patient were found specimens of Anchylostoma duodenale.

A vote of thanks to Dr. Coats brought the work of the Section to a conclusion.

PUBLIC MEDICINE.

At the meeting on Thursday, Aug. 15th, Dr. PARSONS (Local Government Board) read a paper on Disinfection with reference to the Control of Epidemics. He did not see any advantage in disinfecting the infected air of sick rooms by chemical means, for active chemicals, if present in sufficient quantity to be effective as disinfectants, would render the air irrespirable. It was easier to get rid of it and let its place be taken by fresh air. The contagia of most infectious diseases appeared to be destroyed when fully diluted with fresh air. The poison of typhus fever was notably so, but that of small-pox did not appear to be, and it had been proposed that, instead of ventilating small-pox wards into the open air, the air from them should be extracted through a flue and burnt in a furnace, or he might suggest that a steam blast might be used to extract the air and disinfect it at the same time. For the disinfection of excreta corrosive sublimate was the best disinfectant. Care was necessary in its use. Books might be disinfected by dry heat. For house disinfection, fumigation with sulphurous acid or chloric gas—the latter preferred,—followed by thorough cleansing and scrubbing, the removal of wall-paper, and lime-washing, were to be recommended.—Dr. Caldwell Smith, Dr. W. Squire, and Dr. E. W. Hope spoke on the subject.

The next subject discussed was Infectious Disease occurring in Hotels. Dr. C. H. Allfrey, Dr. Hutchinson, Dr. Aston, Dr. Littlejohn, Mr. Loe, Mr. Ogilvie Grant, Dr. Major Greenwood, Dr. Whitelegge, Dr. Eastes, Dr. Hirst, and Dr. MacLaurin spoke on the subject. The following resolution was adopted by the Section:—That it be recommended to all keepers of hotels, hydropathic establishments, and boarding-houses in a town to form themselves into an association having the following objects: (1) An agreement to insist upon the removal as soon as possible of all members of an infected family. (2) An agreement to require the signature of every visitor to a declaration that none of his or her party has recently been suffering from any infectious disease, or has been exposed to known contagion. (3) The establishment of a register of hotels certified as being in a perfect sanitary condition. (4) The provision of a detached building for the isolation of infectious or doubtful cases.

Dr. MAJOR GREENWOOD contributed a paper upon the Disposal of Town Refuse. He urged the necessity of covered vehicles for the removal of refuse, and advocated cremation for the disposal of such refuse.—Mr. BRINDLEY JAMES advocated the total suppression of cesspools, and that each householder should be compelled to burn his own vegetable refuse, and be provided with pails for periodical removal. He also urged the construction of a parish crematorium, for the reduction to ashes of all refuse that could not otherwise be disposed of.—Dr. E. SLADE KING urged that fire was the only effectual agent for the destruction of refuse matter.—Mr. EDGAR FLINN advocated the daily door-to-door collection at a stated early hour of refuse, and the use of dustbins large enough to contain the dry refuse collected during the twenty-four hours.—Dr. C. F. Moore, Dr. Parsons, Dr. Ballard, Dr. Jessop, Dr. Cameron, Dr. Littlejohn, Dr. Caldwell Smith, and Dr. Greenwood joined in the discussion.

On Friday, Aug. 16th, Dr. J. T. ARLIDGE read a paper upon the Sources of Lead Poisoning in the Arts and Manufactures. In the form of ore, lead was productive of plumbism among miners and smelters, being injurious to the former chiefly in the shape of dust, and to the latter in that of vapour. It was, too, as a vapour that it produced its noxious effects among the makers of the oxides of lead in the process of calcination. In the case of metallic lead, plumbism was a result among those who frequently handled it—such as file cutters, the rollers of sheet lead, the makers of leaden pipes and utensils, of shot and lead foil, weavers employed at Jacquard looms furnished with weights, plumbers, and casters of leaden toys and of letter type. In the character of an alloy, it proved mischievous with pewterers, the makers of soft metallic capsules, and of inferior German silver or pinchbeck. Further, metallic lead and lead alloys became indirectly the cause of illness when employed to form utensils for the storage or preparation of articles of food or of luxury, as snuff and tobacco, or for the construction of pipes for conducting or drawing off fluid. The making of white lead or the carbonate of lead and the use of lead by house-painters were the most frequent sources of poisoning. Among pottery artisans the proportion of cases was very high. Its poisonous consequences were also encountered among the mixers of paints and colour-makers, and those employing it as a flux or in the preparation of enamels or glazing materials. Another class of workmen amongst whom the evil effects of lead were seen were the makers of floor-cloth and linoleum. Other miscellaneous trade operations in which lead played its part as a poison were found in the business of lapidaries and cameo-makers; in that of brush-makers, who employed it to colour the hair or bristles; in that of picture-frame making, where the raised pattern was formed by a sort of cement or putty into which lead entered as an ingredient; in the less justifiable operations of whitening Brussels lace, and of colouring and weighting of sewing threads and woven tissues; also in the colouring of vulcanised indiarubber, so commonly used for feeding-bottles. He concluded the survey of lead poisoning by mentioning the introduction of the metal into drinking water; into porter, beer, cider, lemonade, or fruit juices, any of which might have stood in contact with lead or its alloys in the form of pipes or capsules; into food preserved in lead foil, or into food cooked or salted in vessels on the surface of which lead occurred as a glaze.—Dr. Ballard, Dr. Sinclair White, Dr. Whitham, and Dr. Holdsworth joined in the discussion upon the paper.

Dr. ARLIDGE read a second paper upon the Effects of Occupation upon Health. In order to obtain precise results upon this subject it would be necessary to ascertain the number of persons engaged in the various industries concerned, the diseases occurring among them for a series of years, the character of those diseases, the conditions of employment, and the materials used in performing it. He knew none better fitted to make such observations than medical officers of health, and he trusted that many of them would undertake the task.—Dr. SINCLAIR WHITE had tried for two or three years in Sheffield to tabulate the deaths in some thirty or forty of the principal trades. He had found that the death-rate among the needle-grinders was not very much greater than among the ordinary artisans throughout the country. Among puddlers and men working round hot furnaces he had found that the amount of bronchitis, consumption, and kidney diseases was very great.—Dr. UNDERHILL had only been able to find one case of "colliers' consumption" in twenty years' work among that

Digitized by Google

class. The old disease, that used to be called "black spit," seemed to have quite disappeared.—Dr. CALDWELL remarked that this disease was still frequent in Scotland. Deficient ventilation might account for it.

A communication from the Worshipful Company of Plumbers having been brought before the Section, pointing out the desirability of a national system of registration of plumbers, Dr. H. Tomkins moved, and Dr. Caldwell Smith seconded, the following resolution, which was unanimously adopted: "That this Section strongly approves the movement set on foot by the Worshipful Company of Plumbers, as serious defects in the plumbing work of dwelling-houses are constantly leading to disease and ill-health, and demonstrate the need that exists for the more rigid supervision of plumbers and their work."

Dr. SINCLAIR WHITE read a paper upon Lead Contamination in Drinking-water. He pointed out that the size, age, and purity of the lead piping employed, the length of time the water remained in contact with the lead, the pressure of the water in the pipe, the temperature of the water, and the admixture or otherwise of air with the water, had each more or less influence in determining the amount of lead which any given water would take up. Laboratory experiments must thus be received with caution. He had found that acid moorland water invariably acted on lead, and the intensity of the action was in direct proportion to the degree of acidity; new lead piping was acted on more than old lead piping; the amount of lead which an acid water would dissolve went on increasing for the first twenty-four hours, when the action usually stopped; afterwards some of the dissolved lead was deposited, and at the end of six days there was considerably less lead in the water than at the end of the first day. Other things being equal, the greater the pressure under which the water was stored, the greater amount of lead was taken up; and an increase in the temperature of the water increased its lead-dissolving power. As remedial measures, he suggested the substitution for lead piping and lead-lined cisterns of other materials, such as wrought iron, tin, and glass-lined iron; the removal of lead from the water, or treating the water before distribution so as to do away with its solvent action.—Dr. T. B. FAIRCLOUGH was of opinion that much of the anæmia and physical degeneration apparent in large towns was largely due to the constant drinking of small quantities of lead, the amount of lead palsy and lead colic being by no means a true indication of the real amount of lead poisoning in a district. Soft waters were those to be avoided; yet corporations trusted to surface waters to fill their reservoirs, having gone to the moors for catch-ground instead of to the springs. The only safe water for domestic use was spring water of sufficient hardness not to take up lead under any circumstances. Lead poisoning generally occurred more frequently in summer than in winter.—Dr. TOMKINS suggested that a very thin lining of tin in house pipes would obviate the danger of lead contamination.—Dr. ROBERTS said that water filtered by charcoal did not dissolve lead.—Dr. Arlidge, Dr. Jessop, Dr. Underhill, Dr. Deville, and Dr. Whitelegge also joined in the discussion.

DISEASES OF CHILDREN.

On Thursday, Aug. 15th, Dr. CHURTON (Leeds) read a paper on Tubercular Meningitis following slight injuries to the head, drawing attention to the cases which form the subject of judicial investigation, as in the case of school-children having been struck by their teachers. He said that no simple injury to the head was likely to cause meningitis in healthy children, but in tuberculous cases much less violence was followed by meningitis.—The PRESIDENT (Mr. Scattergood) said he had seen cases which bore out Dr. Churton's experience, and he reviewed the medico-legal aspects of the question.—Dr. ASHBY agreed with Dr. Churton as to the pathology of these cases.—Dr. CHURTON, in his reply, commented upon the illegality of striking the children.

Mr. CHURCHILL described the ordinary methods of operating for Hare-lip, and then illustrated the modifications which he is in the habit of adopting with a view to obtain accurate coaptation of homologous structures and a fine linear scar. Being a face deformity, it is obvious that minute care and attention to detail are needful for success. He favoured the retention of the pre-maxillary bone in double hare-lip, but urged that it should be pressed into its proper position, so as to retain the artistic profile. The date of the operation should be in the early months, before the commencement of dentition. Hæmorrhage may be best controlled by digital compression before the insertion of the pins. To avoid hæmorrhage into the mouth the surgeon should not incise the alveolar margin of the buccal membrane. The cheek being elastic and easily transposed towards the mesial line, very large gaps may be closed in without much strain upon the pins. The mechanical means he used were finer than those usually adopted. Messrs. Maw have in stock some finely-tempered steel pins about an inch long, made specially for the purpose. Cutting pliers were not required. The inflexibility of these pins was very important for maintaining accurate coaptation of the buccal and cutaneous edges, and for properly controlling the hæmorrhage. After securing the pins with the usual turns of finely-waxed silk, dumbbell-shaped pieces of Leslie's plaster should be applied, so as to grasp the whole surface of the cheeks.

The work of this Section was concluded on Thursday.

THERAPEUTICS.

This Section was occupied on Thursday with a discussion upon Food for Infants and Invalids, introduced by Dr. Burney Yeo, and joined in by Dr. Sidney Martin, the President of the Section (Sir Wm. Roberts), and others.

On Friday morning the Section, having completed its work, adjourned to the General Infirmary, where Dr. Trevelyan gave a demonstration of the Suspension Treatment of Locomotor Ataxy.

THE INTERNATIONAL MEDICAL CONGRESS OF 1890.

As organising committee of the International Medical Congress to be held in Berlin next year, Professors Virchow, Von Bergmann, and Waldeyer have issued the following resolutions. The Congress is to be opened on Aug. 4th and closed on the 10th. It is to consist of diplomated physicians and surgeons who have had registered themselves as members and have taken tickets of membership. The registration fee is twenty marks, and each member will receive a copy of the Transactions. The purpose of the Congress is purely scientific, and its business will be transacted in sections. The Committee of Organisation will cause the definitive officials to be elected in the first sitting of the Congress—namely, a president, three vice-presidents, and an indefinite number of honorary presidents and of secretaries. In the first sittings of the various sections a president and a sufficient number of honorary presidents will be elected, the latter to preside alternately with the former. Owing to the difference of languages, a sufficient number of secretaries will be appointed from among the foreign members. After the Congress the Transactions will be edited and published by an Editing Committee appointed by the presiding officials. The general sittings are intended for debates regarding the work and general relations of the Congress, and for addresses and communications of general interest. Such addresses are to be delivered only by members requested to do so by the Committee of Organisation. Proposals relating to the work of the Congress must be made to the said committee before July 1st, 1890. The committee will decide whether they shall be adopted or not. All discourses and communications in the general and in the sectional meetings must be delivered to the secretaries in writing before the close of the sitting. The Editing Committee will decide whether and in what compass these writings are to be printed in the Transactions. The official languages used at all meetings will be German, English, and French. The bye-laws and programmes will be printed in all three languages. It is permitted, however, to use another language at the meetings for brief remarks, provided that one of the members present undertakes to communicate the meaning of such remarks in one of the official languages. Introductory discourses in the sections are to be limited, as a rule, to twenty minutes; in discussion only ten minutes are allowed to each speaker. Students of medicine and other persons of both sexes who are not physicians, but feel interested in the debates, may be invited by the president, or may receive permission to attend the sittings.

THE LANCET.

LONDON: SATURDAY, AUGUST 24, 1889.

THE International Congress of Hygiene, which has just terminated its bi-annual session in Paris, and has arranged to meet again two years hence in London, is an institution destined to exercise considerable influence on the legislatures of civilised countries. Dr. BOURNEVILLE, Deputy to the French National Assembly, very frankly and openly declared that it was the sanction given to his proposals by the various International Congresses of Hygiene which enabled him to obtain from Parliament a law for utilising Paris sewage on the land. Madame TKATCHEFF described new laws destined to protect the health of workers in Russia. These laws bear the date of 1882 and 1885. The first International Congress of Hygiene was held at Brussels in 1876. Who shall say how far the reports of M. le Baron DE SUZOR and other official and unofficial Russian delegates, who have regularly attended all these Congresses, may have contributed to bring about the enactment of those laws that will throw a gleam of health and joy on the dark picture drawn by Madame TKATCHEFF of the high death-rate, the disease, degradation, immorality, and drunkenness prevailing among the working classes of Russia? How often has some local practitioner unknown to fame, some village pioneer in the cause of hygiene, fought and overcome local obstructiveness by describing in glowing terms the importance of these International Congresses, the immense number of delegates that attended, the variety of nations represented, and the State receptions provided by the Governments of the countries where the Congresses met. Then, when the desired impression is created, a very big volume is produced. It is the official report of one of these Congresses; it contains a debate on the question at issue, and a resolution carried in the sense of the reform advocated. Will the village obstructives resist that which was approved by 678 delegates, representing the united wisdom of twenty-eight nationalities? But if such Congresses are useful as a means of encouraging national and local progress, their higher mission is to bring about international measures. With the frequency and rapidity of international intercourse the international assimilation of prophylactic precautions becomes more and more indispensable. For instance, a person is ill with small-pox or scarlet fever at Dover; his clothes and bedding are removed and carefully disinfected before he is allowed to go out and mix with other people. But twenty-one miles away, at Calais, a Frenchman is suffering from the same complaint; no disinfection is enforced, and after an hour's sail he can land at Dover, during his convalescence, without any precautions whatsoever having been taken. Evidently much greater security would exist if the same methods of disinfection, isolation, &c., were practised in both countries.

The fact that, in the face of such obvious reasons, England should for so long have remained inactive, and left to Belgium and France the honour of initiating the movement in favour of international sanitary reform, is a regrettable circumstance which we cannot satisfactorily or creditably explain. In any case, we have not neglected this important movement. From its infancy, from the Paris Congress of 1878, we have given the largest publicity to the various Congresses, and have protested over and over again that the number of English delegates attending was not in keeping with the importance of English progress in sanitation. With one single exception—the Turin Congress,—and so as to increase the number and importance of the English delegation, we have sent our special correspondent to attend every congress held; and to him are due the fullest descriptions written in the English language, and published in our columns, of the International Congresses of Paris (1878), of Geneva (1882), of the Hague (1884), of Vienna (1887), and Paris again in 1889.

But, after all, it is of little use lamenting over the past. Our only desire is to show that, as a nation, in the comity of nations, we have lost ground in this respect; and that, therefore, we must, by some extraordinary effort, redeem our reputation and take up that leading position which, considering the progress of sanitation in England, we have a right to occupy. It seems that England is at last beginning to move in the matter, for the Eighth—it should have been the First—International Congress of Hygiene will meet in London in the first week of August, 1891. We must see that this Congress, though held so late in the history of the movement, shall be the best so far as its practical results are concerned. Anything short of best would be a moral disgrace for England. *Noblesse oblige*; and in the matter of Congresses—that is to say, of government by public opinion—England stands first among the great nations of the world. We must organise the Congress in a manner worthy of a nation long accustomed to free institutions; and, if this is ably done, the Congress will differ very materially from its predecessors. We do not deny the utility of abstract theoretical discussions; there may be a little time to spare for such academic debate at the forthcoming Congress; but the greater part of the work should be confined to a distinct purpose, to the adoption of short pithy resolutions, that can be easily reproduced in every organ of publicity throughout the world, and which, by reason of this publicity, shall directly influence the legislatures of the different countries. A lamentable feature in the recent Paris Congress was the absence of the lay press. The medical journals in France have given lengthy reports of the Congress, and those who are technically concerned will be able to consult the voluminous official reports of the proceedings, which will be published in the course of a few months. But hygiene is essentially a popular question. It is of no use for medical men, engineers, and architects to agree as to certain principles of health unless the great mass of the people also understand these things—and, understanding, are willing to sanction their practical application within the privacy of their homes. The work of these Congresses, to be useful, must be essentially an educational work. From each Congress a series of short resolutions should proclaim to the world, in simple terms, some great principles of hygiene, and how these principles can be applied to all nations. This the Paris Congress has done, but in a somewhat confused and unsystematic manner. Also the pro-

Digitized by Google

fessional men who met in Paris have been too much absorbed by professional considerations, too readily satisfied with publicity in professional organs, and have not thought enough of the outside public, on whom it was, above all, necessary to exercise an educational influence, and without whose votes and support but little can be done. Nevertheless if there is thus still some room for improvement in the management of this international agitation, we gladly and without hesitation render all homage to the bold initiators who for so many years have worked to promote the movement. The French Society of Public Medicine and Professional Hygiene was the first to propose, in 1878, that these International Congresses should be a permanent institution, and should meet every two years. Since that date this Society has rendered eminent service as an international link between sanitary reformers of all countries, and we cannot better conclude these remarks than by congratulating its two most active secretaries, Dr. NAPIAS and Dr. MARTIN, on the very efficient and courteous manner in which they have helped to promote, on an international basis, the cause of sanitary progress.

THIS question which has been raised into such prominence by the Glasgow judicial inquiry, to which we referred in our issue of Aug. 10th, has long agitated the minds of thoughtful men. It is this. To what extent is it right to permit the consumption by man of the flesh proceeding from tuberculous animals? There was presented to the International Veterinary Congress, assembled at Brussels in 1883, an elaborate report compiled by Messrs. A. LYDTIN (Baden), G. FLEMING, and VAN HERTSEN (Brussels), which entered with some minuteness into the history of opinion on this very subject. That Congress resolved that only such flesh was permissible as proceeded from animals suffering from tuberculosis in its earliest stages, with very limited lesions and absence of evidence of lymphatic infection. Even prior to that, however, attention had been drawn to the question in this country, one of the earliest to do so being Professor WALLEY, who reminds us that resolutions were passed at Veterinary congresses and meetings five or six years ago urging the inclusion of tuberculosis under the Contagious Diseases (Animals) Act. A not inconsiderable impetus was given to the discussions by the work of Dr. CREIGHTON upon Bovine Tuberculosis (1881), and by his paper read before the Section of State Medicine at the London International Congress. Dr. CREIGHTON then, following VIRCHOW, considered that the bovine disease had characters distinct from those of human tuberculosis, and his argument for transmissibility was based on the detection post mortem of lesions, in children especially, which closely simulated those of "Perlsucht." But, as we have already pointed out, there now appears to be overwhelming evidence of the identity of the human and bovine affections, and the criterion has shifted from the merely anatomical characters of the neoplasm to those of the bacillus of KOCH.

In the inquiry held at Glasgow before Sheriff BERRY this latter test was made the basis of the whole matter. The various witnesses for the prosecution and for the defence were subjected to examination and cross-examination upon the bacillus tuberculosis to an extent which compels admiration of the manner in which the advocates had mastered their briefs. It does not appear that the bacillus was exhibited to the court, and it may be feared from some of the evidence given that the notions held concerning its precise nature were somewhat crude and faulty. Nevertheless, the doctrine of the infectivity of tubercle, and of the bacillus as the *fons et origo mali*, was so strenuously and widely adopted (so far as we can gather, only one expert confessed that he did not "believe" in it), and had so much weight assigned to it, that it undoubtedly largely influenced the view taken by the judge. Yet it would have been quite possible to have argued the case and gained it without reference to the bacillus at all, and seeing how obscure is yet the question of its precise mode of action, this course might even have been adopted with advantage.

The cause of action lay in this: Two carcases, one of a bullock apparently in prime condition, and one of a cow, had been condemned by the local authority; and the clerk to the magistrates and council of the city petitioned the high sheriff of Lanark to enforce this order. The one animal exhibited marked evidence of recent tubercular pleurisy, and the other of more chronic tubercular disease of the lung. The flesh appeared to be healthy, but the carcases were condemned, the case evidently being made a test one in order to enforce a practice which is carried out in Edinburgh, Paisley, and Greenock of condemning the flesh of all tuberculous beasts as unfit for consumption. The inquiry lasted over several days, and for the prosecution there were called fifteen witnesses; for the defence nineteen. Amongst the experts there appeared for the prosecution Dr. J. B. RUSSELL, Dr. LITTLEJOHN, Mr. ARCH. ROBINSON, Mr. A. MCGEOGH, Mr. A. E. MAYLARD, Dr. JOSEPH COATS, Professor W. LIMONT, Professor THOS. WALLEY, Dr. J. WALLACE, Professor J. MCFADYEAN, and Professor JAS. MCCALL; and on the other side Mr. G. GOLDIE, Dr. FRANCIS IMLACH, Dr. T. W. HIME, Dr. S. GIBBON, Dr. ALFRED HILL, Dr. J. W. MASON, Dr. JOHN DOUGALL, Mr. W. ANDERSON, Dr. WM. G. YOUNG, and others. There is much that is interesting in the details of the evidence given by these gentlemen, which is available for any who desire to peruse it, but it will hardly bear condensation, and we prefer to limit our remarks to the main points raised by the learned counsel on both sides in summing up the case from their respective points of view. Mr. URE, for the prosecution, pointed out the indubitable presence of tubercular disease in each of the animals, which derived further significance from the fact deposed to by some witnesses of the existence of tuberculisation of the lymphatic glands (pre-pectoral in both cases, and inguinal, also, in one), showing that the disease was disseminated. Mr. URE held that great importance attached to the disease being due to the bacillus, which was admitted by Drs. IMLACH and HIME, who gave evidence for the defence, with the inference that, given tubercle in one part of the body, a general systemic infection is to be implied. He cited the significant conclusion arrived at by the Departmental Committee of the Privy Council, and the resolutions of the Paris Congress, as to the condemnation of the flesh of tuberculous animals being used for food, the former statement being that "although the bacilli may be found but rarely in the flesh, still the chance of their being present, either there or in the blood, is too probable to ever allow of

Digitized by Google

the flesh of a tuberculous animal being used for food under any circumstances, either for man or the lower animals." And it was clearly shown in evidence that ordinary cooking would not suffice to destroy the bacilli. Mr. JAMESON, for the defence, pointed to the serious economic effects of such wholesale condemnation, and speaking of the case of the cow took up a position which was certainly a tenable one. The disease in that animal, he pointed out, was quiescent and limited; indeed, it seems to have been of the nature of "obsolescent tubercle;" and it was given in evidence by only one witness, Mr. MCGREGOR, that the pre-pectoral gland was infected. Apart from this, the disease was strictly a "local" tuberculosis, and Mr. JAMESON held it to be "pure imagination" that the blood, and therefore the flesh, of such an animal could be infected. He attributed all the "commotion" to the results of the Departmental Committee and Paris Congress, and hinted, not obscurely, that the scientific world was running wild over this question of bacillary infection. Mr. COMRIE THOMSON, who also spoke for the prosecution, minimised the extent of economic disaster likely to ensue from the condemnation of tuberculous meat, and he maintained that the possibility of transmission of disease to man by his ingestion of such meat had been absolutely proved. Mr. M'KECHNIE followed for the defence, and analysed closely some of the scientific evidence given as to the presence of bacilli in the diseased animals.

In giving judgment for the prosecution, Sheriff BERRY based his decision largely on the fact that from the involvement of the lymphatic glands there was evidence that the disease had commenced to spread through the system, and that it was not merely local, as contended. He did not, therefore, need to endorse to their full extent the declarations of the Departmental Committee and the Paris Congress, so that the decision does not strictly bear on the question of wholesale condemnation, or of the inclusion of tuberculosis under the provisions of the Contagious Diseases (Animals) Act. Nevertheless it is probable that in Glasgow the authorities will now proceed to act as they have been doing for some years at Edinburgh, Greenock, and Paisley, and condemn all meat from tuberculous animals; whereas it was given in evidence by Mr. GOLDIE, Dr. S. GIBBON, and others that at most other important centres the flesh, if of healthy appearance, is invariably not condemned, although some tubercular disease may be present in the body. For our own part, we cannot but think that to condemn as unfit for human food the flesh of an animal presenting, say, an old cretified nodule in the lung, would be both foolish and wasteful; yet it may well be objected that there is no line of demarcation to be drawn between the grades of tubercular infection, and no test (short of obvious generalised miliary tuberculosis) that the system is impregnated with the virus that could be employed to determine when to accept or when to reject such flesh. For, indeed, the infection of lymphatic glands in the vicinity of the local focus may not be evidence of systemic infection, although it is generally assumed to be so, since these glands may act as barriers to the further extension of disease. We would by no means be understood as upholding the somewhat lax inspection that allows flesh to be passed as healthy because of its external appearance, and without regard to the existence of tubercular disease in the animal; but we must candidly confess that there is danger of being so far carried away by the bacillary doctrine as to shut our eyes to the plain teachings of morbid anatomy on the arrest and cure of tubercular lesions. Moreover, M. NOCARD'S experiments ("Congrès pour l'Étude de Tuberculosis," Paris, 1888) seem to show that the flesh of tuberculous animals very seldom contains the virus, for it was quite exceptional to induce tuberculosis in guinea-pigs inoculated with the juice of such flesh, and he deprecated the adoption of too rigorous measures. The question is one which, although so long debated, is still obviously open to further inquiry. Towards this the Glasgow case will furnish valuable material, and meanwhile we would urge our veterinary *confrères* to suggest and enforce prophylactic measures whereby this bovine "scourge" may be mitigated amongst the herds, so that it may come to be a rare thing for tuberculous beasts to be sent to market.[1]

A FORTNIGHT ago we called attention to the very important subject of the treatment of tuberculous disease of the hip, particularly as presented by Mr. HOWARD MARSH in his lectures at the College of Surgeons. It may be useful to look at the present state of surgical therapeutics for an allied affection—tuberculous disease of lymphatic glands; for the points of resemblance, and those of contrast too, are striking. In passing, we may notice that the influence of age is as well marked in the etiology of the one affection as the other, and the special prevalence of tubercle in the glands of the neck and of the abdomen seems to be due to the liability of these glands to slight inflammatory irritation from disordered conditions of the mouth, tonsils, pharynx, or intestine, in the same way as the great frequency of tubercle in the hip-joint is to be explained by the proneness of this joint to suffer from jars and strains.

It is, however, to the operation of erasion as practised upon tuberculous glands that we wish to refer. The operation itself is almost too well known to need description. It consists of a puncture with a knife into the abscess cavity, and then through this puncture a small Volckmann's scoop is introduced and passed into the gland, the entire contents of which are removed. The operation is one of the simplest in surgery, and certainly one of the most successful, although if not done thoroughly it may fail. The cavity left by it quickly fills up, and only a fine linear cicatrix is left to indicate the seat of the previous disease. We have here the complete removal of a local tuberculous focus followed by speedy and oftentimes permanent recovery, and at first sight such a result seems to warrant the inference that similar treatment applied to other tuberculous lesions would be both equally successful and equally innocuous. But the special features of the case must be carefully borne in mind. First of all, the tuberculous matter is confined within the tough capsule of a gland, and it is both an easy and a safe procedure to scrape away the entire contents of the capsule without the risk of wounding or removing other parts, or of leaving behind some of the infected tissue. This is done

[1] As to the prevalence of tubercular disease in such animals, the following recently published statistics of the Berlin markets may be quoted. Of oxen and cows there were 1296 tuberculous out of 98,397, or 1·36 per cent.; of pigs about 1 in 1300; of calves about 1 in 4000; and of sheep and goats 1 in 5000. The proportion of tuberculous cattle in the Glasgow market was given at ½ per cent.

Digitized by Google

without what may be called mutilation; no functional disability is experienced by the patient; and in these respects the operation stands in striking contrast to many of those practised for tuberculous disease in other parts—for example, in joints. There the operation itself is a serious one, the limits of the infected material are not well defined, important healthy structures have to be divided or removed, and, if the tuberculous disease is cured, more or less serious after-effects are experienced, such as lameness, ankylosis, and deformity. In the case of tuberculous glands, operation is attended with the maximum of benefit and the minimum of evil; while in the case of a joint, it is far from certain that the surgeon will secure the maximum of good, while it is sure to be accompanied with ill results, which may vary from slight to very grave. But there are other considerations, too, which render the comparison we have instituted inexact. From their position in the absorbent system it cannot be doubted that tuberculous glands are more liable to infect other glands and distant parts of the body than is a tuberculous focus in a bone or joint, so that the operation which removes this source of danger is more urgently called for in the one case than in the other.

Again, the possibility of applying other forms of treatment differs in the two cases. In the one case rest can be carried out to a degree that is practically impossible in the other, and nothing is more striking than the beneficial effect of perfect rest in tuberculous joint disease. No such treatment can be so efficiently carried out in the common case of tuberculous glands in the neck. It must not be lost sight of, also, that it is comparatively easy to guard against a repetition of the strain or similar local irritation that has led to the development of a tuberculous arthritis. But it is usually difficult or even impossible to protect glands from all similar local irritations. It is therefore illogical to argue from the case of a gland to that of a joint. The essence of the disease is the same in both cases, but the peculiar conditions of each are far too important to neglect. But we may at any rate learn this—that experience of tuberculous glands shows that for operation to be really successful it should be attended by complete removal of the tuberculous material, and at the same time the healthy or non-tuberculous parts should be interfered with or removed to the smallest possible extent.

It is very important to notice that there is reason to fear that even such a slight operation as the erasion of a tuberculous gland may be followed by a general infection. All cases bearing upon this ought to be carefully reported, and it would be interesting to know whether this result is the direct or the indirect effect of the operation; whether it is due to the introduction into the circulating blood through the wounded bloodvessels of the tuberculous virus; or whether the administration of an anæsthetic, or the infliction of a trauma, or nervous shock, renders the tissues of the body generally a suitable soil for the growth of the tubercle bacilli.

THE Leeds meeting of the British Medical Association will rank high among the records of similar gatherings. The attendance was large, over nine hundred members being present; the public addresses attained a high range of merit; the discussions in the various Sections were vigorous and practical; while the hospitalities, public and private, were worthy of the reputation of Yorkshire. It was expected that a town of medical traditions like Leeds—the town of the HEYS, the NUNNELEYS, the TEALES, and of SAMUEL SMITH—would give a cordial welcome to the profession, and this expectation has been fully realised. The efforts of the Reception Committee to ensure the comfort and pleasure of their guests were happily seconded by the Marquis of RIPON, the Bishop of RIPON, Sir JAMES KITSON, and the Mayor of Leeds, whose receptions added much to the interest and enjoyment of the meeting. Fortunately the weather, which has shown such extraordinary perturbations of late, did not seriously mar the success of the proceedings. With the exception of Wednesday there was no rain of consequence; and that most critical day, the Saturday devoted to excursions, was everywhere favourable to out-door enjoyment.

We speak elsewhere of the address of Mr. WHEELHOUSE, who must be congratulated on his discharge of the duties of President.

Dr. HUGHLINGS JACKSON gave a subtle address upon those obscure relations of Evolution to Medicine regarding which we are still but feebly groping our way towards the light—assured, however, that the day of fuller illumination is not far distant. Mr. TEALE spoke lucidly on Detail in Surgery. While Sir JAMES CRICHTON BROWNE delighted a large audience by his powerful and humorous handling of the topic of the Hygienic Uses of the Imagination. His prescription of fiction as a wholesome mental tonic and a preventive of the degeneration of mental stagnation into downright lunacy may seem superfluous at a time when novels pour in ceaseless stream from the press, but the general truth of his remarks cannot be controverted, and they may be commended to the attention of those crabbed moralists who denounce fiction as an unmixed evil, forgetting that the taste for it is one of the most natural and earliest to develop of all our inherited faculties.

The sectional work at Leeds was in many respects eminently satisfactory. Broad general questions of practical interest were in the main chosen for discussion; they were introduced in most cases by acknowledged leaders of the profession; the succeeding speakers were selected on grounds of special knowledge; while visionary and academic questions were avoided. The discipline that such meetings affords should be most wholesome to persons who are capable of profiting by experience. Some men, no doubt, think themselves ill-used if they do not secure attention; but they should note the thronging crowd and the eager interest that await the man who, by the thoroughness of his methods and the convincing character of his facts, gives some fair presumption that he is about to inaugurate some advance, however small, in the ancient art of healing.

In the Section of Medicine, the first day was mainly occupied with a discussion introduced by Dr. DOUGLAS POWELL upon Tubercular Disease in Serous Membranes. Among the many points brought out clearly in the course of this discussion was the fact, emphasised by such speakers as Dr. BROADBENT and Dr. POWELL himself, that the bacillicide treatment of phthisis rests on no sure foundation, and is unsupported by trustworthy evidence. On the second day, Dr. PAVY introduced the very timely and practical question of the significance of albuminuria, with

Digitized by Google

special reference to life insurance. It was remarked by one of the speakers that the very fact of such a question being discussed indicated a change in medical opinion, since a few years ago the presence of albuminuria would have been accepted without further question as a bar to insurance. This is true, but it must be admitted that the advocates of "physiological albuminuria" did not shine in the course of the discussion, and that the sense of the meeting seemed to be best summed up in the loudly applauded remark of Professor GAIRDNER, that "albuminuria is always a danger-signal.' One point of real practical importance, especially to the busy man of general practice, came out clearly—viz., that it is better to adhere to the old tests and to ignore any albumen which is not shown by heat and nitric acid. The interest of the Section reached its maximum on the third day, when Dr. ARMAND RUFFER of the Pasteur Institute gave a lengthened and powerful address upon the results of the Pasteurian Method in Hydrophobia. We have not space to do justice to the subject in this brief sketch, but, put briefly, M. PASTEUR has succeeded in reducing the mortality of those bitten by undoubtedly rabid animals from somewhere about 20 per cent. to less than 1 per cent., a result which we venture to think one of the most brilliant of the many achievements of science. Dr. RUFFER'S masterly marshaling of his facts, his demonstration that only cases of bites of really rabid animals were counted, all doubtful cases being presented in a separate category, his refutation of the calumny that hydrophobia has ever resulted from the inoculations, and his recital of M. PASTEUR'S prodigious difficulties, and with what patience and wisdom they have been overcome, all profoundly impressed his hearers.

Good work was done in the Surgical Section under the able presidency of Mr. JESSOP. The Treatment of Cancer of the Rectum, of Surgical Diseases of the Kidney, and of Prostatic Enlargements were the main topics considered. As regards the last of these, Mr. MCGILL'S operation of supra-pubic cystotomy was received with considerable favour.

In the Obstetric Section, the always important subject of Placenta Prævia was brought forward by Dr. BRAXTON HICKS, whose combined method of turning was favourably reported upon by several speakers. The vexed question of the value of Electricity in the Treatment of Uterine Fibroids was also warmly discussed upon another day. It is to be desired that this question should not degenerate into mere polemic, but it must be confessed that the general drift of British opinion seems to be setting in strongly against the method of APOSTOLI.

The Section of Public Medicine was well sustained, and, as usual, it aroused much attention on the part of the lay press. The Training and Position of Medical Officers of Health, the Control of Epidemics, the Disposal of Town Refuse, Lead Poisoning, and Water Contamination were among the many very important questions ably handled by competent speakers.

Of the other Sections we cannot speak particularly. Sir WILLIAM ROBERTS' gravity was evidently more than once severely tried by some of the suggestions which were offered to him as President of the Therapeutic Section, but a little untempered enthusiasm for treatment is a fault that leans to virtue's side, and one to which enlarging experience will probably supply an efficacious antidote.

The excursions of the Association were among the most successful ever held. Scarborough, Ilkley, York, Rievaulx Abbey, Harrogate, Fountains Abbey, Ripon, Settle, and Gordale Scar were among the many places visited. In all cases a hearty welcome and a kind hospitality awaited the members joining in the excursions.

DR. BRUCE LOW'S report to the Local Government Board on Diphtheria in the Halstead District[1] offers a striking example of the confusion which exists as to the extent to which that disease is present amongst us as a cause of sickness and of death. For a series of years diphtheria has persisted in the Halstead registration district and in neighbouring districts in Essex, Suffolk, and Cambridgeshire, and of late it has shown marked increase. But when the mortality statistics came to be examined it at once transpired that the fatal attacks of diphtheria had been associated, and this often in the same houses, with other deaths certified under a number of different names, amongst which croup, laryngitis, membranous croup, ulcerated throat, tracheitis, &c., figured, and the occasional addition of words indicating sudden collapse or syncope is extremely significant of the true nature of the disease really in question. Indeed, during a group of years "croup" alone caused 66 deaths, whilst 63 others were set down to diphtheria. And when all these fatal throat affections are added together, it appears that whilst 27 and 23 deaths occurred during quinquennial periods ending respectively 1878 and 1883, no less than 103 took place in the five years ending 1888. The deaths were mainly amongst young children, and whilst they had occurred in nearly every part of the registration district, certain parts—as, for example, Halstead town and the village of Sible-Hedingham—had suffered much more heavily than other places.

No proper estimate as to the extent to which this throat mischief had prevailed can, however, be made; for information accidentally obtained in villages where it was alleged that there had been no prevalence of diphtheria for years past went to show that when the school registers were examined and other data inquired into, sore-throat, becoming more and more severe until a "croup" death took place, had been by no means uncommon, and that occasionally the sustained group of attacks had ended in one or more admitted deaths from diphtheria. In short, no proper history could be prepared of diphtheria in the Halstead district which did not take accurate account of a multitude of attacks of throat disease of varying severity and infectiveness; and the inquiry, instead of attempting to deal with the circumstances leading to the origin of the prevailing disease, had rather to content itself with an attempt to identify the chief conditions under which diphtheria had manifested itself in a district where "sore-throat" of varying type had been endemic if not universally prevalent.

Personal infection is regarded as having been a powerful means of conveying the disease from one to another, although the extent of its operations cannot well be measured in view of the circumstance that throat mischief

[1] Eyre and Spottiswoode, East Harding-street, E.C.; Adam and Charles Black, Edinburgh; Hodges, Figgis, and Co., Dublin. Price 1s.

Digitized by Google

and its prevention seem to have been the concern of no one unless it happened to be regarded as diphtheria. School influence appears to have been largely operative in this respect, and instances of extension of the disease came under notice which were easily explained when it transpired that children returned to school, after ailments more or less severe, exhibiting definite diphtherial neuroses, which affected speech, vision, &c. One special school seems to have been influential in this respect, and its influence determined the marked incidence of the disease in one-half of Halstead, on the east side of the river Colne. Factory influence amongst the silk-workers in Halstead and its vicinity is also considered, and this especially in connexion with the conveyance of the disease to the surrounding villages by young women who, working in the factories, live away from home except from Saturday to Monday in each week. The extent to which diphtheria has prevailed in certain villages appears to have depended, amongst other things, on the number of their residents who thus travelled to and from a factory district. As to sanitary circumstances, nothing definite as to causation could be made out; indeed some of the worst localities escaped, whilst others in their immediate vicinity and having better health conditions were severely attacked. Other influences, such as gross conditions of slaughtering, are considered in connexion with the cause of the disease; but, apart from the communication of the infection by means of persons not themselves suffering from recognised throat ailment, nothing very definite could be made out by reason of the overshadowing effect of the attendance at one of the infant schools. Summarising the experience derived from this inquiry, Dr. BRUCE LOW adverts to the facilities favourable to the spread of the disease by reason of the failure to recognise its characteristics in mild attacks; to the absence of evidence of any connexion between insanitary surroundings and the prevalence of diphtheria and allied throat disease; to the fact that there is distinct suggestion of the communication of the infection by means of clothing, much as is the case with scarlatina and measles; and to the circumstance that a very potent factor of the disease in Halstead town was school influence.

THE demand for a Court of Criminal Appeal, to which the course of the MAYBRICK trial has very naturally directed public attention, has been renewed under very favourable auspices. Lord ESHER has expressed a very strong view in favour of the proposal, and lends to it the support not only of high judicial position, but also of great personal weight. In the debate which arose in the House of Lords on the 15th inst., the like sentiment was expressed by Lord FITZGERALD and Lord HERSCHELL, and it may therefore be hoped that means will be found for giving legislative effect, or at least legislative form, to the proposal. At the present moment the discussion lacks a little in point. The argument that if the determination of controversies touching property warrants the maintenance of Courts and a system of appeal, much more should questions which touch life and liberty receive equal consideration, is one of undeniable and irrefragable force. And, indeed, if the two matters stood on exactly the same footing that argument would be absolutely conclusive. But it must be admitted that the functions of a jury are very different in the two cases. In the case of a civil action the tribunal has to exercise the utmost impartiality between the parties, and if upon the whole the evidence preponderates on one side the verdict must be given accordingly. But in a criminal action the position in which the jury is called upon to stand is very distinctly different from this. Not perfect impartiality, but a state of mental prepossession in favour of the innocence of the accused person, is the frame of mind which is legally recognised as being the right attitude for a jury empanelled to try the issue of guilty or not guilty. This is a very broad ground of difference, and, while it explains, it goes far also to justify the absence of any machinery of appeal upon questions of fact in criminal cases which characterises our juridical system. Indeed, it may even be pressed still farther, for we think reflection will show that where the conditions of the problem vary so widely it can hardly be said that the success of the system of appeal established and approved by experience in the one case affords any guide to the conditions of success in the other. And, in truth, it would be difficult to imagine anything less calculated to promote the ends of justice than the adoption intact of the complicated and slow machinery of appeal in use for civil business for the purpose of administering the criminal law.

All this being frankly admitted, there still remains a broad and solid ground for the demand which has arisen. The unanswerable argument in its favour is that in a certain number of cases an appeal has been created by the force of circumstances. Improvised out of the Royal prerogative of mercy, it is carried by more or less informal methods before a tribunal constituted at the Home Office, of which the Home Secretary is the only responsible member, and the colleagues whom he may summon into consultation with him are mere assessors. With such a manifestly makeshift arrangement it were easy to find fault. But it is more profitable to study it with a view to discovering the true principles upon which a permanent and recognised Court of Criminal Appeal can be established. The circumstance that, in spite of constitutional theory, such an irregular tribunal as we have described has to be constituted three or four times a year is a very strong argument in its favour as a branch of our system of legal administration; while the further circumstance that, in spite of its fugitive character and ill-defined constitution, it serves its purpose fairly well, is the best possible evidence that in it may be found the elements indispensable to its success. Whenever, therefore, the Legislature undertakes the task of adding a Court of Criminal Appeal to our institutions of government, it will do well to find its model at the Home Office, and, boldly discarding the methods of civil procedure, to advance along the line of developing and systematising the practice which has been created under pressure of circumstances by successive Home Secretaries. A tribunal so constituted would differ greatly from any recognised Court at present exercising jurisdiction within this realm, but it would probably conform pretty nearly to the outline which Lord ESHER has sketched of a Court affording an appeal "as large as possible on law, facts, and sentence, with the largest discretionary power as to any means by which, in the opinion of the Court, it could be assisted to arrive at a right, just, and merciful conclusion."

"Ne quid nimis."

HOLIDAY DANGERS.

THE holiday season has dangers special to itself, and some of these which can most easily be avoided should be borne in mind by the many who are now flocking to seaside and other resorts. The selection of the holiday residence is a point of the utmost importance, and yet most people, in taking either a house or lodgings, think of little else than the general appearance of comfort and the number of rooms available, altogether ignoring such questions as the character of the drainage and the source of the local water-supply. Many who are thus thoughtless have taken precaution to see that the sanitary state of their permanent home is such as to involve them in no risk, and it is these people, who are in no way acclimatised to the influence of unwholesome conditions, who run the greatest risk when subjected to such conditions whilst away from home. In a certain number of our seaside and other pleasure resorts a registry is kept by the sanitary officers of lodgings and houses which are wholesome in point of construction and water-supply, and it would be a distinct safeguard if the public generally were to consult either the medical officer of health or his registry of houses before making any arrangement as to residence. Disconnexion of waste and overflow pipes from the drains, and severance by means of an air-break between the house drains and the sewer, should be insisted on before any house is regarded as wholesome in this respect. As a rule, surface wells should be looked upon with the greatest suspicion, and their surroundings should be carefully investigated. And where a public service is available it should be seen that the water for drinking and cooking purposes is never drawn from a cistern which supplies a watercloset. Some guarantee should also be obtained that no infectious disease has recently occurred in the house; and on this point the opinion of the medical officer of health should usually be obtained. As to food-supplies, care is generally needed for the exercise of some control over the stimulus which at the onset change of air, and especially sea air, gives to the appetite; and owing to the sudden demand which is generally made on the local milk service, especial precaution is needed as regards this article of diet. There is a common impression amongst some persons that little risk attaches to milk which comes from the country, whereas it is essentially in the country that the danger lies, and very often the danger is greatest in the most rural places, for it is precisely in remote localities that unrecognised attacks of specific sore-throats and other infectious ailments in the families of those having to do with cows and small dairy farms pass altogether unnoticed. And if, during a busy season, the temptation arises to temporarily increase the milk-supply by the aid of water, it is in the rural areas especially that the quality of the water is most open to suspicion. Holiday-time is, therefore, the time, above all others, in which all milk should be boiled or otherwise cooked before use. These are some of the points to be held in view by intending holiday-makers, and most of the dangers we have adverted to can best be avoided by a preliminary consultation with the ordinary medical adviser, who in turn can procure from the local health officer the needed information as to the sanitary circumstances of the localities and houses where the holiday is intended to be spent.

MR. WHEELHOUSE ON MEDICAL EDUCATION.

IT is a happy circumstance that Mr. Wheelhouse took the occasion of his presidential address at Leeds to give his views on Medical Education and Examinations to the profession. Whatever may be thought of these opinions, they are those of one who has had a long and large experience combining in a rare degree that of a general and consulting practitioner and of a teacher in surgery. Mr. Wheelhouse in the Medical Council has been somewhat silent. He has been half buried in committees, and perhaps, particularly as the chairman of the Business Committee, he has felt hindered in stating his views of Medical Education with so much fullness and force as he showed at Leeds. But he made up for it at the recent meeting, and declared boldly in favour of a short pupilage, an extension of the time of medical education, and a reduction in the number of examinations. Mr. Wheelhouse pointed out with much force that formerly men took eight years to complete their medical education, whereas now it is all crowded into four, though the majority of men, as a matter of fact, take five to get through the ordinary examinations. The very moderation of Mr. Wheelhouse's argument should secure for it great attention. He admits that the new race of students are better educated than their predecessors, and, in the long run, make better practitioners. But for the first few years of their professional life they are inapt, unfamiliar with the common work of practice and the common types of disease. The result is that they do not make good assistants, and are apt to make annoying and humiliating mistakes. His great remedy for this is a short pupilage, which he would place at the beginning of professional study, when men are not above learning and not expected to be above mistakes, or afraid of having their mistakes pointed out. Opinions may differ as to when and how this familiarity with common disease is to be acquired, but Mr. Wheelhouse's fearless address will do much to secure the supply of a great want in medical education. His remarks on the faults of examinations, both as to method and number, were equally fearless and serious. It is undeniable, he says, that far too often the best students are rejected and the worst pass through with triumph. His great remedies are to eliminate unnecessary subjects from the examinations, and to secure that candidates shall have more time and leisure for their serious work. One of his chief proposals is that the written part of the examinations should be taken at the different schools, instead of in London. It is coming to be recognised that the unjust rejection of a good student is a very great evil, which, as it can never be undone, should occur with extreme infrequency. Mr. Wheelhouse has done much to hasten this reform. His somewhat sanguine forecast of the triumph of medicine in a not remote future is worthy of study. The one plague which he does not see his way clear to curtail and control is syphilis, of which he speaks in tones that resemble those of Dr. Gowers, on which we have lately commented. Otherwise, his belief in the progress of medicine is large and millennial—that is to say, millennial for all but the medical profession, who, in the fulfilment of his views, will find their occupation gone. It was kind in Mr. Wheelhouse to add that these results would not accrue in our generation.

THE FIRST SOUND OF THE HEART.

THE part recently issued of the *Archiv für Anatomie und Physiologie* contains a paper by Dr. Ludolf Krehl, in which, from investigations conducted in the Physiological Institute of Leipsic, he has arrived at the conclusion that the contraction of the cardiac muscular fibres is the principal cause of the first sound, instead of being, as is now generally admitted, merely an accessory cause, or, as some will have it, entirely inoperative. The part played by each of these

Digitized by Google

factors in the production of the sound can only be finally determined when the intensity of the full sound is ascertained, as well as the intensity of the several possible factors. But the difficulties of the case are well known; for whilst, on the one hand, the systole of the heart is found to consist of a single and sudden contraction, which it is held can produce no sound, since it produces only a single wave, and whilst it is rendered indistinct by the incompetency of the auriculo-ventricular valves,—on the other hand, such experienced observers as Ludwig and Dogiel have satisfied themselves that under circumstances in which the sudden tension both of the auriculo-ventricular valves and of the vascular walls is impossible the first sound is still indubitably audible, from which it would appear that one, if not the chief, agent in its production is the muscular sound. The researches of Krehl were undertaken to test the truth of Ludwig and Dogiel's observations under conditions in which the play of the valves was still more stringently prevented, and this he believes he has accomplished by the employment of an ingeniously constructed little apparatus, consisting of a tube, from the extremity of which an expanding crown can be protruded, and by this means, when the instrument is introduced into the cavity of the heart, the valves can be firmly pressed back against the walls of the arteries. The animals used were dogs, and whilst after the insertion of the instrument one observer auscultated the heart, another alternately pressed in and withdrew the crown. The results obtained were that when the auscultator knew that the crown was thrust out and the valves compressed against the arterial walls, he perceived that the systolic sound was duller and a little less strong; but when with averted face he was unaware of the position of the crown, he was unable to distinguish any difference between the periods when the valves were acting and when they were not acting. This result obtained incidental confirmation by the fact that in all instances as the animals bled to death the second sound disappeared, whilst the first sound was still for some time distinctly audible; and additional evidence is to be found in the circumstance that, when in such cases the ventricle had ceased to contract and the auricle alone acted, a sound was clearly perceptible—that is, when the play of the valves had certainly ceased. He does not consider that he has been able to determine from his investigations whether the cardiac contraction is a simple convulsion or a tetanus, but he thinks that the sound may arise from the friction of the muscular fibres against each other; and this is supported by the observation of Dr. MacWilliam, that a sound is audible on simple convulsion or spasm of the voluntary muscles.

THE WEST-END FEVER "SCARE."

WE must confess that we have considerable sympathy with those who are regarded as having indulged in the so-called "fever scare" in the West-end. It is true that the outbreak has been limited, that it has been mild in character, and that it has not cost many lives, but the mere fact of a number of houses scattered over a wide area being simultaneously attacked with this disease is in itself a matter for anxiety; and the circumstance that the houses attacked were of a sort to make it practically impossible that the disease was due to any ordinary sanitary defects attaching to the drains or otherwise is the reverse of reassuring. Whether the actual cause is known or not has not yet transpired, but the public at present hear only of some unnamed condition which resulted in a group of enteric fever cases in Mayfair and the neighbourhood on the 25th and 26th of July last, the cause itself being apparently involved in some obscurity. If it be really obscure, then there is no guarantee whatever that it may not recur, and for this reason alone people have a right to show their anxiety by taking part in the "scare." The sanitary authority can certainly not guarantee that a recurrence of the disease will not be as virulent in its effects as the recent one has been mild, and for this reason alone it is to be hoped that an exhaustive inquiry will be carried out until the cause is found, and any possible recrudescence of the disease has been prevented. For our part, we think that the circumstances of the outbreak justify a strong suspicion against milk as the vehicle of the infection, and this aspect of the question will doubtless be thoroughly looked into. Indeed, the President of the Local Government Board has promised that the inquiry made into the outbreak by Dr. Corfield shall now be supplemented by further investigation of the circumstances by one of the medical inspectors of his department. In the meantime, we would, as we have often done before, urge that safety in the consumption of milk cannot be expected unless the consumers boil or otherwise cook all milk used in their households. There is, in all probability, no article of food which is so apt a vehicle of the contagia of disease as milk in its natural state.

NAVAL HYGIENE.

EQUAL in importance to a seaworthy fleet is it to have seaworthy sailors, and whilst we are engaged in testing the fighting qualities of our ships we ought not to forget the men to whose care they are committed. And this is the more important, since it is obvious that increase in the number of our ships does not really mean an increase of naval power unless there is a corresponding increase of sailors to man them. It is out of our province to inquire into the truth of the statement that the naval review and manœuvres have shown that the home fleet is undermanned. The statement, however, has been made by responsible persons, and will no doubt receive due attention from those especially qualified to discuss such matters. Whatever that discussion may reveal, one fact is evident, that discontent exists among the seamen and petty officers on board certain of the more modernly constructed ships, not on account of unavoidable discomforts brought about by the exigencies of their construction and the necessary sacrifice of space for the accommodation of huge coal bunks, enormous boilers, and machine-worked guns, but because no adequate attempts seem to be made to improve conditions of life on board. Ever since the days of Lind, the medical officers of our fleets have endeavoured to the utmost of their ability to improve the condition of the sailor's life on board ship; and we have only to turn to the text-book on Naval Hygiene to see what excellent work has been effected. But, unfortunately, their efforts have not always been appreciated or seconded by the authorities, and many hints which, if adopted, would have improved the sanitary conditions of recently constructed ironclads have been passed over unheeded. Among the many desirable improvements would be a rearrangement of the sailor's dietary. The science of victualling ships has made enormous strides of recent years, but with all this the sailor's dietary is even more defective than the soldier's, which has recently been subjected to severe criticism. The allowance as it stands is defective in quantity; it is also too frequently, as we hear, defective in quality. Owing, moreover, to the crowded condition of the ships, sufficient space is not always allowed for the cooking ranges, and many minor discomforts arise from this which might be obviated by the employment of improved ranges. We pass over the monotony of the prescribed rations, merely remarking that there is no excuse for them nowadays, and that a more varied dietary could easily be arranged at no extra cost. But we must heartily condemn the practice of serving out

Digitized by Google

nothing after the mid-day meal till the mid-day meal of the next day, except a little tea or cocoa with hard biscuit. This cannot be sufficient to keep a man in health, exposed as the sailor is to cold and wet above and to steam and damp below deck. What refreshment can there be, after the previous evening fast, to come down after a night or early morning watch to a breakfast of dry biscuit and cocoa? Instead of allowing the men to gorge themselves at mid-day, the allowance should be divided and a good evening meal secured. We could speak of many other points calculated to improve the health of the men and render the service more popular, and such reforms must be undertaken if we hope to man our fleets with really seaworthy sailors.

THE HASLAND POISONING CASES.

AT the recent Derby Assizes Mary Ann Whitfield was charged with the wilful murder of her son, Ernest Whitfield, at Hasland, Derbyshire, on June 27th, 1888. The prisoner was the wife of an engine-driver, and the mother of four children. They came to live in Hasland in November, 1887, and the four children were all in apparently good health until June 5th, 1888, when one of them (Alfred) was taken ill. He appeared to be in a lethargic state, had a difficulty in defecation, vomited, and was puffy about the face. The medical attendants, Mr. R. P. Jeffreys and Mr. J. Goodwin Shea, found albumen in the urine, and treated the case as one of nephritis. There was no contraction of the pupils; there were sickness and semi-consciousness more or less until his death on the 18th. A certificate of death from nephritis, with uræmia, was given. On the 26th the youngest child, Ernest, was taken ill, and was seen by Mr. Shea, who found roughened breathing, dulness of the lungs, dilated pupils, and unconsciousness. He treated him with hypodermic injections of sulphuric ether, but the child died on the 27th, and on the 28th Mr. Shea gave a certificate of death from congestion of the lungs. It was well known that the prisoner was a woman of drunken habits. The smallest inquiry would have elicited the fact that both children were insured, Alfred for £10, Ernest for £6. The two deaths occurring within so short a period was, in the absence of any infectious disease, suspicious, and even though a certificate was given, it seems strange that an inquest was not held there and then. The boy's body was buried, and the prisoner's husband was subsequently ill on several occasions, the illness always occurring on a day when he was off work and at home. The symptoms were loss of the use of his legs, sickness, and the same lethargic state as had been observed in the children. Fortunately he recovered. On Feb. 4th last the prisoner was found by another son (Henry) in the attic in an unconscious state, and, on Mr. Symes being called to her she was found to be suffering from narcotic poisoning. She was arrested for this attempt on her life, and all these suspicious events demanded a full inquiry, which was held, the bodies of both children being exhumed on Feb. 20th, and a post-mortem examination made by Dr. Fielden of Chesterfield, who removed the viscera and forwarded them to Mr. Alfred Henry Allen, county analyst. That gentleman found no trace of poison in the viscera of the boy Alfred. In those of Ernest he found meconic acid in small amount, but no trace of morphia. It was proved that the prisoner had sent her son Henry to buy laudanum, and that she had it in the house. Many other very suspicious facts were proved. The case was a very clear one, and Mr. Justice Hawkins, who has tried many cases of murder by poisoning, including those of Lamson and Berry, summed up in such a manner as to show that he had no doubt of the prisoner's guilt. But to the astonishment of everyone in court, and to the prisoner most of all, the verdict was "Not guilty." Two days later she pleaded guilty to the charge of attempting to commit suicide. The learned judge told her that she must not go away with the notion that the verdict of the jury removed every stain from her character, and removed the cloud of doubt and mystery which hung over that young boy's death. The jury acquitted her because the evidence was not sufficiently satisfactory to them to find her guilty. That was all the ground upon which she was acquitted. She was sentenced to four months' imprisonment with hard labour.

FRIENDLY SOCIETIES.

THE report which the Parliamentary Committee has presented upon Friendly Societies deals generally with the important subject referred to very much upon the lines which have from time to time been pointed out in these pages. Thus, for instance, on the question of infantile insurance, the finding of the committee is that the allegations of culpable, and even wilful, neglect and violence have been in some cases well founded, and that the object of such neglect and violence has not been disconnected with the sums payable on the death of the children. But at the same time they also say, "It must be admitted that insurance for burial expenses is highly valued by the working classes for perfectly legitimate reasons, and that an unnecessary hardship would be inflicted upon them were it prohibited." They accordingly conclude in favour of better regulation as against prohibition, a conclusion in which we entirely concur. We do not, however, feel equally well satisfied with the method of regulation to which the committee appear to incline. They remark that the medical certificate of the cause of death does not require the medical man to make any inquiry as to whether the child's life is insured; and, further, that it is probable that medical men are very often not acquainted with the provisions of the Friendly Societies Act of 1875, and that hence it happens that practitioners are not unfrequently asked for, and give, more than one certificate as to cause of death, the additional certificates being avowedly obtained for the purpose of getting insurance moneys. Hence they recommend that the Registrar-General should add to the form of medical certificate of death a column demanding particulars of insurances on the life of the deceased, of whatever age, to be filled up by the medical man. This surely is a case of putting the saddle on the wrong horse. If medical certificates are really given in the circumstances specified, they are wholly irregular, and for their purpose worthless. The Friendly Societies Act, with which a medical man may quite innocently be unfamiliar, but which the officers of the societies are at least bound to know, expressly prohibits the payment of insurance money except upon a certificate issued by the registrar of deaths. If the societies choose to pay upon a certificate issued by somebody else, they surely should be blamed, and not the innocently ignorant medical man. So with the proposed remedy. It is the wholly illusory one of requiring the medical man to tabulate the result of inquiries which he is to be called upon to make as to insurances—a subject wholly foreign to his professional duties. This would be inexcusably burdensome in any case, even if great good could be expected to result from it. But, as a matter of fact, the cases would be so numerous in which, at the time of the giving of the medical certificate, the survivors would not know, or would pretend not to know, whether any insurances were subsisting, that the certificate would be quite illusory. For such a gain we must protest, and protest most strongly, against the further addition of an irksome and thankless office to the large volume of a medical man's already subsisting statutory duties.

THE ISOLATION OF ENTERIC FEVER IN MANCHESTER.

AN early if not the first official act performed by Dr. Tatham, the newly appointed medical officer of health for Manchester, has been to induce the corporation to take a step which will remove a distinct blot from their sanitary administration. Hitherto Manchester has required the notification of enteric fever, but when they have learned the existence of that disease in their midst they have been content to leave it there, instead of securing the isolation of the sick. We are not prepared to say that isolation in hospital is a necessity in every case of enteric fever, and we freely admit that a distinction, as regards its communicability, may be drawn between enteric fever and some of the other infectious fevers; but we have no hesitation in saying that the retention of all enteric fever patients in their own homes in our ordinary towns and villages is distinctly fraught with danger to the public health, and that their removal to hospital is often necessary in the interests of the patients themselves. But the need for isolation in such a town as Manchester must be obvious to anyone acquainted with that city as a whole; and we imagine that, although Dr. Tatham's present proposal is only to send such cases of enteric fever to hospital as "cannot safely be treated at home," the number coming within that definition will be by no means a small one, whether regard be had to the safety of the public, or to the safety and chance of recovery of the sick persons themselves. The truth is that a large number of children and young adults continue to be attacked with enteric fever in Manchester; that the incidence of the disease is essentially in the poorer parts of the city, where the means of its safe treatment are notoriously absent; and that, as Dr. Tatham states, the disease is an eminently communicable one under conditions such as are by no means exceptional in Manchester. The report submitted to the corporation practically asked that a failure in the sanitary organisation of the city—which we believe had been deliberately decided on, and which has certainly been acted on for a number of years—should no longer prevail; and we congratulate Manchester on the confidence which has been shown in their new officer by the resolution which was come to on the subject, and which was to the effect, "That the report now read be adopted, and that the Health Committee be instructed to make such arrangements as may be proper and necessary for carrying out the recommendations thereof."

SECONDARY GROWTHS IN CARCINOMA.

IN the August number of the *American Journal of the Medical Sciences* is a short paper by Dr. Heneage Gibbes, in which he describes the results of his investigations on the development of secondary cancerous growths in lymphatic glands. By staining sections of infected glands with picro-carmine, rosaniline sulphate, and iodine green, he is able to distinguish by colour four different parts. The connective tissue is stained by the picro-carmine, unchanged lymph cells stain bluish green, cancer cells stain green, and large multinuclear cells stain purple. He further finds that while the majority of the irregular nuclei of the multinucleated cells stain a deep purple colour, here and there one more rounded in outline will take a faint green stain. He is led to believe that on reaching a lymphatic gland the cancer cells divide and form the multinuclear masses; after a time one of these nuclei becomes separated from the mass and forms an independent cell in the resting stage; after this it becomes active, germinates, and produces another multinuclear cell. He has seen nothing to justify the view that a so-called spermatic influence can be exerted on connective-tissue cells to lead to their producing epithelial cells. Dr. Gibbes classifies cancers into: (1) those derived from protective epithelium, such as that of the skin, tongue, and gullet; (2) those derived from the epithelium of simple secreting glands, such as that of the pylorus and rectum; and (3) cancers derived from epithelium which forms the parenchyma of the true secreting glands, such as the breast.

THE INTOLERANCE OF SWITZERLAND TOWARDS ENGLISH MEDICAL PRACTITIONERS.

MR. T. K. TAPLING, M.P., does good service in directing the attention of the British public and Government to the absurd state of mind of the Swiss Government towards English medical practitioners in Switzerland. In a letter to a contemporary on Aug. 20th, he says that the Swiss Government has arrived at a final decision hostile to the English doctors. This is a most illiberal attitude on the part of Switzerland. Mr. Tapling is informed that about £2,000,000 of money go into Switzerland annually from British tourists, to say nothing of the freedom of our markets to Swiss labourers and workmen. Nor does the state of our British medical law give much show of reasonableness to the action of the Swiss Government and the illiberality of a clique of Swiss medical men who are understood to urge the Government in this matter. We have not yet recognised, so as to admit to registration, Swiss diplomas. But no law and no body in this country would interfere with a Swiss doctor prescribing for his compatriots here. Yet the Swiss are so intolerant to their English visitors as to disallow an English doctor in a hotel prescribing for an English visitor, and to forbid a Swiss chemist to dispense his prescriptions. It is conceivable that an English visitor might die for want of assistance in a Swiss hotel with capable physicians and surgeons of his own country in the same hotel. Such a state of matters is alike incredible and intolerable, and cannot be too soon or too strongly complained of by our Foreign Secretary.

WHITE-LEAD POISONING.

CASES of plumbism still continue very numerous in districts where white-lead manufactories are situate, in spite of the stringent regulations which are supposed to be enforced. As we have before pointed out, many of these cases are due to an extreme susceptibility of the individuals affected, for in many instances, when an inquiry has been made, it has been found that, whilst many of the old hands have never, during a long course of employment, suffered in the slightest degree from plumbism, there are others who, after repeated attempts, and apparently using similar precautions, are attacked after only a few weeks' work. An example of such extreme susceptibility has just been the subject of an inquest held by Dr. Danford Thomas, concerning the death of a young plumber, who was a strong and healthy man two years ago, before he began to do plumbing work and handle lead. The coroner remarked that he had never before had a death brought before him of lead poisoning where a victim was a plumber, and remarked upon the extreme susceptibility that must have existed to have brought about a fatal result. It is well to bear in mind this fact, for undoubtedly many cases of plumbism occur in private practice which for a time may be overlooked owing to the difficulty of connecting the symptoms with the use of lead. Thus cases which at first were thought to be progressive muscular atrophy have proved to be lead palsy caused by the use of hair-dye. A young lady was attacked with severe abdominal colic, the nature of which was unsuspected until the patient mentioned casually that a few days before she had been engaged in painting some vases. Even sleeping in a house in which some of the lower rooms are being painted, though removed

Digitized by Google

from the actual sleeping-room, has caused undoubted plumbism in some of the more susceptible inmates. Besides this, even if the more marked features of lead poisoning are absent, contact with small quantities of lead will in some persons produce decided ill-health, such as obscure pains in the limbs, numb feelings in the fingers, muscular twitching, and anæmia. Of all the salts of lead the carbonate is the most poisonous, and it is with satisfaction we hear that a process has been instituted which has received the approbation of Sir Henry Roscoe, by which the dangers attendant on the manufacture of white lead can be avoided, and by the substitution of another salt, the white sulphate, the risk of using white paint may be considerably, if not altogether, removed. Whether sulphate of lead can replace the carbonate for all purposes remains to be seen. So far as it has been used for woodwork it seems to have satisfied Sir Henry Roscoe, and if with a wider application it is found that it can be used for most of the requirements of trade, a great step will have been taken towards protecting the health and life of those engaged in the manufacture and use of this subtle and dangerous metal.

THE FOURTH INTERNATIONAL PRISON CONGRESS.

OVER and above its great interest to the student of State Medicine, this Congress, which is next year to meet at St. Petersburg, will have special attractions for the Englishman. Coinciding as it does with the centenary of John Howard's death, it will be utilised for the bestowal of international honours on that noble philanthropist. The Government of the Czar, bearing in mind the fact that it was on Russian soil—at Kherson in fact—that Howard met his death in 1790, desires to show its appreciation of his philanthropic work by offering a prize for the best monograph on "The part filled by John Howard in the History of Penitentiary Reform." Competitors must write in the Russian or French language, and their work must include a biography of John Howard and a review of his publications; a characterisation of penitentiaries at Howard's time, and a full list of all the innovations completed or proposed by him in these institutions; an estimate of Howard's influence on the subsequent course of penitentiary reform; and a bibliography of all his writings. Competing monographs must by May 1st (i.e., according to the Russian almanac, the 15th), 1890, at latest, be in the hands of "The President of the Organising Committee of the Fourth International Prison Congress at St. Petersburg." They must be furnished with a motto, and accompanied by a sealed letter containing the writer's name and address. The jury which will examine the monographs will be elected by the Congress itself, and it will award two medals of gold, a larger and a smaller, as well as silver medals and certificates of honourable mention. The competitor to whom shall be adjudged the larger gold medal will also receive 2000 fr. (£80), and his monograph will be inserted in the Proceedings of the Fourth Congress, while he will also have the right of reprinting it. All competing monographs, whether printed or in writing, which have not been withdrawn within two years by their authors are to be destroyed; and, lastly, the result of the Competition will be published in the Bulletin of the International Penitentiary Committee, and also in the Proceedings of the Fourth Congress. Besides the above-mentioned competition, there will be another at the instance of the conductors of the *Prison Discipline Review*. Its subject is the following: "What in the most civilised nations has been the historical development of the institutions relating to the correctional education of minors who have been convicted of crimes at common law, or who have been put in custody for idleness and vagabondage, or with a view to paternal discipline?" The conditions of the competition are identical with those of the preceding, except the following modifications. The competing monographs, in writing or in print, may be written in any language, but there must be a French translation of the same appended. The successful competitor will receive as prize the sum of 2000 francs (£80) from the conductors of the *Prison Discipline Review*. The organising committee of the St. Petersburg Congress will be entitled to publish the successful monograph in the Proceedings of the Fourth Congress, while the author will, at the same time, have the right of reprinting it.

SEASIDE HOSPITALS IN ITALY.

IT is owing mainly to medical inspiration and initiative that the Italian seaboard, with its many attractive bathing quarters, is now so extensively utilised for the scrofulous and rickety youth of both sexes, as well as for the convalescent poor when they leave the hospital. At Rome, for instance, an arrangement has been effected between the civic authorities and the administration of the hospices at Porto d' Anzio to convey to that seaside resort, and to maintain there for fifteen days at least, all the children threatened with tabes or afflicted with rachitis in the various orphanages of the city. For two months relays of these little unfortunates will thus have the benefit of a "fortnight at the sea," with all the restorative and exhilarating effects that such a sojourn implies for the youthful invalid "in populous city pent." This practice—which is becoming universal throughout Italy for the summer months, and which it is in contemplation to render operative all the year round whenever change of air and scene is indicated for the sickly or convalescent poor—might with great advantage be imitated nearer home, where the seaside resorts are quite as numerous and as inviting as in Italy, and where the means at the disposal of the public are infinitely more affluent than is the case with "the youngest of the European powers."

THE INHALATION OF DUST.

DR. KUNZE, in his inaugural thesis for the M.D. degree of the University of Kiel, publishes as a contribution to the diseases caused by the inhalation of dust a series of examinations of lungs so affected. In all these dust was found microscopically, and after chemical tests in the various anatomical and histological parts of the lungs and in the interior of the lymphatic vessels numerous leucocytes were found covered with the dust. Being arrested in its progress, it causes inflammation producing hyperplasia of connective tissue, especially where a dense network of lymphatic vessels exists. Dr. Kunze also proved that the degree of alteration in so-called "dust lungs" depends not merely on the quantity of the dust inhaled, but also on its greater or less morphological power of injuring the tissue. He concludes from his experiments that even the greatest alterations in these lungs—such as nodes, indurations, and vomicæ—are mainly produced by the inhaled dust, and that tuberculosis is only an occasional coincidence. The least serious alterations in the lungs resulted from the inhalation of lamp-black, the particles of which are very fine and little injurious; the most serious, from the dust inhaled by earthenware manufacturers and stonemasons. The lungs of a locksmith showed only a moderate hyperplasia of connective tissue, the dust consisting partly of the finest particles of iron. In a worker in oxides of iron the lungs were found full of small granules, and the morbid changes in the tissues were very considerable. The lungs of gold miners were generally indurated and atrophied; the dust in these cases is exceedingly fine. Sand produced numerous circumscribed hard nodules and thick indurations. In cloth

Digitized by Google

manufacturers, the lungs, in spite of their contact with an enormous quantity of organic dust, presented but few indurations. In the lungs of two stonemasons induration and tuberculous disintegration were observed; all the other lungs were entirely free from tuberculosis of any kind, an observation which was verified by the absence of tubercle bacilli in the muco-pus in the vomicæ.

SENSATION IN FALLING FROM A HEIGHT.

IT is commonly asserted that persons who fall from a height die in falling, and are mere unconscious bodies when they crash against the earth. Perhaps this comfortable conviction has had some connexion with the fact that monuments and other elevated structures have sometimes been chosen by suicides as their stepping-stones to an uncertain future. The feelings of any who have made such perilous journeys will probably remain for long matters of conjecture, though sufficient evidence exists to prove that the mere passage through space, even from considerable altitudes, is not necessarily fatal. There is, indeed, nothing incompatible with life in a swift air transit of a few seconds. It is true that such rapid movement, combined with the tension of suspense, the frenzy or despair preceding an attempt at self-destruction, and perhaps other circumstances besides, may lull the senses into a state of semi-consciousness, but all this is consistent with life. The effective action of these forces, moreover, will depend somewhat on the temperament of individuals. Thus men of steady nerve should feel even so great a change distinctly less than others of weaker nervous organisation. Again, one who falls accidentally is in a different position as regards apprehension and intensity of feeling from that of one who precipitates himself. It is highly probable, however, that in any case the momentary whirl of sense provides that its sudden and usually fatal arrest, if not painless, will entail at most a mitigated pang.

MURDER BY STRYCHNINE POISONING.

GEORGE HORTON, coal miner, was tried at the Derby assizes before Mr. Justice Hawkins for the wilful murder of his daughter by poisoning her with strychnine on May 20th last at Alfreton. The facts of the case were extremely clear, and have been made more so by the confession of the prisoner since his conviction, in which he admits having committed the crime for the sake of £7 insurance money. The deceased child, Kate Horton, was eight years old, and on the morning of May 20th, having been previously in her usual health, she went into her sister's room soon after six o'clock and lay on the bed, "twitching and becoming quite stiff." A woman living in the same house was called to her, and found her eyes and mouth twitching very much, her legs quite stiff, and complaining "that her belly hurt her." She died at seven o'clock, having previously told a neighbour that "dadda gave her some blue stuff out of a bottle in a cup." The prisoner went out about six o'clock, and was previously heard refusing to give the deceased a drink, saying that he would be late for his work. A post-mortem examination of the child's body was made by Dr. Bingham of Alfreton, who found the organs healthy and no marks of violence. In the stomach he found a collection of greenish-blue particles, which were also in the intestines, together with a number of worms. Mr. Allen, the borough analyst, found abundant evident of strychnine, he being able to isolate three-tenths of a grain of it from the stomach, two-tenths from the intestines, and three-tenths from the liver, making eight-tenths in all. The blue particles consisted of ultramarine, which was the colouring matter used in the vermin-killing powders sold by chemists. The prisoner had threatened another daughter, who had formerly, but not recently, lived with him, that he would poison her, and she feared he would. A son of the prisoner was also from home, and the latter had been heard to say that "he had got shut of two children, that he would soon get shut of the rest, and take his hook." He showed some grief when he found the child dead on his return home between eight and nine, but he asked Dr. Bingham for a certificate of death, which was refused. When arrested on the 28th, he said, when charged with the murder, "I have nothing to say." In sentencing the prisoner to death, Mr. Justice Hawkins described the crime as a cruel, sad deed, terrible even to contemplate. It is worthy of remark that there was no proof of the prisoner having purchased any poison, nor was any cup or glass found with traces of it. Taken with the prisoner's confession, this case is a very instructive one. The crime was conceived and carried out with diabolical cunning; to prove it was a matter of difficulty, and, but for the tell-tale blue of the ultramarine, it might have been impossible. It was an apt illustration of the lines:—

> "Murder, though it have no tongue, will speak
> With most miraculous organ."

THE ABUSE OF STICKS AND UMBRELLAS.

A CHAPTER on the proper mode of carrying sticks and umbrellas would afford most persons material for profitable reflection. We have not space for such a chapter, but shall merely notice, with regard to the matter, a few instructive but easily forgotten hints of daily experience. The point, whether of stick or umbrella, figures prominently in the small accidents of every thoroughfare. It is carried or suddenly jerked behind one under an arm, and often painfully near to the persons of passers-by. It is heedlessly thrust in front by the arm of a rapid walker, or anon describes a circle, with some careless hand for the centre. It travels swiftly upstairs at railway stations, performing an aggressive zigzag movement among the crowd of passengers. It forms the centre of the spread umbrella suddenly opened in the teeth of a stormy wind, and in the face of wayfarers. Its uncertain level threatens by turns a shin, a back, or a face, a child's mouth or eye, or the solid front of some portly citizen. "Beg pardon" readily follows if it strikes a mark, but a missing tooth is not so soon restored or a bruise reduced. In such matters no body of regulations can give security, but self-interest alone might teach the careless the duty of watching and guiding aright this apparently insignificant but seriously offensive point.

CRUELTY IN CIRCUS TRAINING.

UNLESS the methods of circus training in this country differ materially from some that still prevail abroad, it must be allowed that the protection afforded by the Prevention of Cruelty to Children Bill has not come a day too soon. The history of an English boy, who was till recently attached to a performing troupe on the Continent, furnishes a pitiful narrative of barbarity and oppression. The lad was apprenticed to a German circus manager when ten years old — that is, at the limit of age prescribed in the Act. For nearly eighteen months he has remained with his employer learning his calling, and enduring much hard usage. If he fell from the trapeze (a frequent occurrence) he was well thrashed. If he failed in the feat of sitting on the ground with legs astride, he was forced into the required position by a woman placing her full weight on his shoulders. After a time the treatment became so unbearable that he ran away, and, though recaptured, finally reached home with the assistance of the British Consul in Barcelona. This is exactly the kind of case which the new Bill is intended to provide for. Some of its opponents object to what they consider to be its needless interference

Digitized by Google

with the abused rights of parents or masters. What place is there, we may ask them, for the rights or the wrongs of a child like this circus boy unless the law provide one? In our own view, there is real cause for disappointment that many children, like this boy over ten, will still be exposed to the hardships of such training merely because their age does not exempt them.

SIR JOHN BANKS, K.C.B.

THOUGH there have been presentiments of the event, it is gratifying to find duly gazetted the gift of a K.C.B. to Dr. Banks, Regius Professor of Physic in the University of Dublin. Our Irish brethren will begin to think that the Government is no longer slow to do honour to those who stand in the great succession of Crampton, Marsh, Graves, Stokes, and Corrigan. It is but fit that the same honour enjoyed by the Regius Professors of Physic in Oxford and Cambridge should be accorded to the Regius Professor of Physic in the University of Dublin. Those who know Sir John Banks best will most rejoice with him in his new rank. Her Majesty may feel assured that she could not have conferred the honour on any Irish physician who better represents all that is urbane in Irish manners and cultivated in Irish medicine, or made a selection more acceptable to the profession in Ireland and the United Kingdom generally.

BACTERIOLOGICAL STUDY OF THE KIDNEY IN TYPHOID FEVER.

DR. KONIAEFF publishes as a graduation thesis (St. Petersburg Dissertations, 1888-89, No. 13) an account of a series of observations made on patients suffering from typhoid fever at the Alexander Barrack Hospital, with the view of ascertaining the existence of typhoid bacilli in the kidney. It was found that "lymphoma" of the kidney occurred in 17 per cent. of the cases in which post-mortem examinations were made, and that typhoid bacilli were present in these centres of morbid change. In some cases bacilli were found in the urine, and it appeared probable that this was the only outlet for the bacilli in the kidney.

THE ELIMINATION OF ARSENIC.

AT the meeting of the Paris Academy of Medicine on July 23rd (*Gaz. Hebd.*, No. 31), M. Marty recalled that in 1863 M. Roussin had pointed out that arsenic could be found in the skeleton, replacing phosphorus, and that its elimination was very slow. M. Brouardel remarked on the medico-legal importance of this fact. He said that formerly it was believed that after arsenical poisoning all trace of arsenic had disappeared from the body by the end of a fortnight or three weeks.

UTERINE CANCER.

DR. L. LANDAU, in a clinical lecture on Carcinoma of the Uterus, first points out the great importance of the microscope in the diagnosis of incipient cancer. He advises the strictest examination of the microscopical diagnosis in all reported cures of carcinoma, considering that erroneous conclusions are frequently due to the ambiguity of many anatomical plates and to insufficient knowledge of the disease. He considers that the microscopical diagnosis itself of incipient malignant growths is still as uncertain as every other method of examination, and that it must remain so until an easily recognisable cause of carcinoma and specific cancer cells have been found. With regard to treatment, Dr. Landau is one of those gynæcologists who in cancer of the cervix greatly prefer excision of the whole organ to high amputation. In discussing the question of the ultimate curability of uterine cancer, he points out the great physical and moral relief afforded to the patients by excision, though the disease may afterwards recur. He recommends that incurable cases should be kept continually under the influence of morphia.

THE ROYAL COLLEGE OF PHYSICIANS.

THE Bradshawe Lecture at the College of Physicians was delivered on Monday last, the 19th inst., by Dr. Norman Moore. The date, in some respects inopportune, is fixed according to the trust under which the lecture is delivered. The President (Sir Andrew Clark), Sir Henry Pitman, Sir Dyce Duckworth, and Dr. Munk were among those present to hear the lecture, which dealt with Visceral Cancer, and was based upon Dr. Moore's extensive pathological experience at St. Bartholomew's Hospital. Several conclusions respecting the development, nature, duration, and dissemination of malignant growths of the various organs were drawn, and stated in clear and concise terms. The lecture will be published in our columns.

DEATH OF DR. THOMAS KING CHAMBERS.

IT is with considerable regret that we have to announce the death, on the 15th inst., at the age of seventy-one, of Dr. Thomas King Chambers, honorary physician to the Prince of Wales. The deceased received his M.D. degree from the University of Oxford in 1846, and was elected a Fellow of the Royal College of Physicians, London, in 1848, of which College he filled the office of censor in 1860-61, was Lumleian lecturer in 1863, Goulstonian lecturer in 1850, and Harveian orator in 1871. Dr. Chambers was a member of the General Medical Council, senior consulting physician to St. Mary's Hospital, consulting physician to the Lock Hospital, and a Fellow of the Royal Medical Chirurgical Society. Among his works may be mentioned "Lectures, chiefly Clinical," fourth edition, 1865; "Some Effects of the Climate of Italy," 1865; "Indigestions, or Diseases of the Digestive Organs Functionally Treated," second edition, 1867; "Harveian Oration and Two Sequels," 1871; "A Manual of Diet and Regimen in Health and Disease," second edition, 1876. Dr. Chambers was also the author of articles on "Catalepsy," "Ecstasy," and "Somnambulism" in Reynolds's "System of Medicine." We hope to give a more detailed account of Dr. Chambers's life and character in a future number. We will only say here that he was a physician of high culture and great originality. His active life and usefulness were unfortunately sadly curtailed by a severe illness some years since. On the death of the late Dr. Rolleston he was appointed representative of Oxford in the General Medical Council. In the work of this body he took an important part, especially in the production of Reports on Medical Education and on the question of Unqualified Assistants.

WOOLLEN CLOTHING IN PHTHISIS.

DR. GRECHKO has examined the effects of supplying phthisical patients with woollen clothing. He finds (St. Petersburg Dissertations, 1888-89, No. 44) that the loss by the lungs and skin is greatly increased only during the first four-and-twenty hours; the temperature of the skin is distinctly increased during the first day, but after that it begins to fall slowly, so that by the end of the week it has become normal. The internal temperature and the blood pressure do not undergo any change.

As we go to press the intelligence reaches us that the sentence of death passed upon Mrs. Maybrick has been commuted by Mr Matthews into penal servitude for life.

Digitized by Google

THE sixty-second Congress of German Physicians and Naturalists meets at Heidelberg from the 18th to the 23rd (inclusive) of next month. A representative body of the profession will on this occasion be elected to take part in the great International Congress which is to assemble in August, 1890, at Berlin. Another feature of the Heidelberg gathering will be the participation in its proceedings of foreign guests specially invited. A new statute will also be formulated by which the Congress will be provided with a governing body, which shall have a permanent seat and standing orders.

AT Rome from the 15th to the 17th (inclusive) of October next will assemble the second Congress of the Italian Medical Association. Among its special features will be reports on "Malarial Infection," by Professors Baccelli and Marchiafava; on the "Pathology and Cure of Nephritis," by Professors Bozzolo and Rattone; and on "Gout," by Professors Cantani and Murri. Other papers and memoirs have been announced to the organising committee, and the whole proceedings are expected to be of an unusually interesting tenour.

Pharmacology and Therapeutics.

SANDELL'S ANTISEPTIC SUBLIMATE PELLOIDS.

THESE pelloids dissolve very easily in cold water, and thus afford a very convenient addition to our means of rapidly preparing an antiseptic solution of any strength that may be desired. One pelloid in a pint of water forms a lotion containing 1 in 4000 of corrosive sublimate. The pelloids are supplied in tubes of twenty at a low price, and will probably be much appreciated owing to the readiness with which they may be employed without tedious weighing and calculation.

THE NARCOTIC PROPERTIES OF CHLORALAMIDE.

Drs. Hagen and Häfter, assistants in Professor Strümpell's clinic at Erlangen, consider chloralamide one of the most reliable narcotics, and recommend that it should be given in a slightly acidulated solution or in wine. They say that the most appropriate cases for its administration are neurasthenia, spinal affections, and heart disease, and recommend a dose of fifty grains. The drug, when it acts at all, produces the desired sleep in half an hour. Its administration in phthisis has not proved so satisfactory, as in some cases it did not act at all, while in others, though sleep was induced, considerable general malaise was complained of on waking. They also gave it one morning to three convalescents from syphilis, who had taken a dose the night before with good effect. The result in all three cases was that the patients slept nearly the whole day, without being deprived of their ordinary sleep the next night. Before the communication of the authors to the *Münchener Medicinische Wochenschrift*, experiments had been made altogether in twenty-eight cases (twenty-five patients and three healthy people), embracing 118 doses of the drug. A decidedly narcotic effect followed in twenty-six cases, superior to that of other narcotics in sixteen, and almost equal to it in ten cases. Complete failure occurred in two cases only—one of paralytic dementia and one of advanced phthisis; in a case of acute myelitis the result was doubtful. In comparing the amide with the hydrate of chloral, the authors decide in favour of the former, on account of its less unpleasant taste, and more particularly because its narcotic effect is decidedly greater than that of the hydrate. Undesirable effects are certainly less marked and of less frequent occurrence with the amide than with the hydrate. They consist generally of slight headache and a somewhat dazed feeling on waking, but such symptoms occurred in only three of the twenty-eight cases; once collapse was noted, which, however, could not with any certainty be referred to the drug. Patients do not become accustomed to the amide of chloral, so that the same dose, however often administered, always has the same effect. The authors point out that the drug has not, as a rule, any specific effect on pain or other symptoms; but they mention a case of cardiac asthma in which the pulse, which had been very unsatisfactory, improved and maintained its improvement.

BROMOFORM IN WHOOPING-COUGH.

Dr. Stepp of Nürnburg publishes in the *Deutsche Medicinische Wochenschrift* a large number of cases of whooping-cough, in which he claims to have obtained most satisfactory results from the internal administration of bromoform. The drug has, according to the author, no ill effect of any kind, and his numerous observations have proved that bromoform, as applied by him, is non-poisonous, and that the pulse and temperature remain unaffected by it. The action of bromoform is entirely different from that of bromide of potassium, as has been observed in epilepsy, the former being rather an excitant than a sedative. Children are ordered from five to twenty drops during the twenty-four hours in very frequent doses. The solubility of bromoform in water being very slight, the mixture requires the addition of alcohol. The author has administered bromoform in about sixty-five cases of whooping-cough, the children mostly ranging in age from six months to seven years. The longest time required for a complete cure was four weeks. Symptoms of pulmonary catarrh in all these cases were entirely absent, or else they were very slight and soon disappeared. No complications existed in any of the cases observed by the author, but Dr. Goldschmidt has treated several serious cases of whooping-cough complicated with pneumonia, completely curing them in a fortnight by the daily administration of bromoform. Dr. Stepp concludes from his observations that under bromoform treatment bronchial catarrh and lobular pneumonia do not generally occur, and that where they exist at the commencement of the treatment resolution takes place with facility and at an earlier period than under other methods of treatment. His observations showed also that the dose of bromoform must be in direct proportion to the severity of the affection and the age of the patient. The system does not seem to become accustomed to the drug, which has, moreover, considerable prophylactic power, so that the other children of a family in which whooping-cough in an advanced stage already exists can be shielded from the disease by being given bromoform. Dr. Stepp believes that bromoform is either excreted unaltered by the lungs or is separated into its elements, and that the free bromine is excreted by the lungs. In this way an effect on the bacilli of whooping-cough could be easily supposed to result.

INTRAVENOUS INJECTION OF CARBONATE OF SODA IN POISONING.

Dr. Sanquirico of Siena treats cases of poisoning by intravenous injection of large quantities of an 8 per cent. solution of carbonate of soda, and so producing a very active secretion of urine. He was able to give the animals he experimented on (rabbits and dogs) considerably larger doses of some poisons that are usually lethal without fatal results, if he at the same time injected his solution of soda. When he used both the soda injection and the usual antidotes, he was able to save his animals even after doses of poison that would have certainly proved fatal if only one of the two modes of treatment had been applied. The only poison which withstood this combined treatment was nicotine. He points out that the diuretic treatment can only be successful when the functional power of the heart and of the central nervous system have not been so seriously paralysed as to prevent antidotes from exercising their influence, or so as to cause a diminution of the secretion of urine in consequence of the weakened action of the heart.

HYDRACETIN IN PSORIASIS.

The *Berliner Klinische Wochenschrift* publishes a paper by J. Oestreicher of Berlin on the therapeutic value of hydracetin in the treatment of psoriasis. He was induced to make trial of this drug by the objectionable secondary effects of the usual remedies for psoriasis. Six patients, one a medical man, were the first cases under the new treatment. Lanolin ointment, with at first 10 per cent. and afterwards with 20 per cent. of hydracetin, was applied once a day, without having recourse to any other external application or to any internal medication. After two or three applications, in every case desquamation ceased, the redness disappeared, the efflorescence became more and more level with the skin, and in a fortnight the cure was generally complete. In all the cases, however, a disturbing element appeared,

Digitized by Google

which gave rise to a suspicion of toxic results of the treatment. After the seventh and before the tenth application of the hydracetin ointment all the patients began to complain of an increasing weakness of the limbs, which gave the impression that they were suffering from a serious internal malady. The skin became pallid, almost waxy, especially in the face, which in places was swollen; the mucous membranes became anæmic and yellowish; in one case general jaundice was present. There was no fever in any of these cases, and the heart and digestive apparatus were normal. The urine was of a dark mahogany colour, with a slight greenish tinge as if containing bile, which was, however, never found by Gmelin's test. Albumen was found in moderate quantity only in those cases which presented most distinctly the appearance of icterus. Nothing else was found in the urine except (by Jaffé's test with hydrochloric acid, chlorate of lime, and chloroform) an increase of indican. It was evident that hydracetin is a poisonous substance, and that it must therefore be used with caution.

ACETOPHONE.

Acetophone, or methyl-phenyl-ketone, which has been employed chiefly by some French physicians as a hypnotic, has recently been studied by Dr. S. S. Kamenski (St. Petersburg Dissertations, No. 70, 1888–89) in the laboratory. He finds that it lowers sensibility and interferes with reflex action. Large and medium doses produce a moderate amount of sleep. It quickens the heart's action, probably by stimulating the accelerator nervous apparatus. It increases the irritability of the respiratory centre, except in large doses, which may arrest respiration altogether. It lowers the blood-pressure by its action on the vaso-motor centre and by weakening the heart's action. Medium and large doses lower the irritability of the brain, and even small doses have a similar effect on that of the cord.

ETHEREAL TINCTURE OF IRON IN CHRONIC NEPHRITIS.

Dr. Wyss of Geneva speaks very highly of the ethereal tincture of iron, or Bestucheff's tincture, as it is usually called on the Continent, in cases of chronic Bright's disease. Five or ten drops of this preparation in a glass of water were given to a large number of patients from three to six times daily, the result being that in more than half the cases the albumen entirely disappeared from the urine, and the œdema and other symptoms were also cured.

THE PARIS UNIVERSAL EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT.)

The International Congress of Hygiene—(Concluded).—Filters.—River Pollution.—The Working Classes of Russia.—Gennevillier and Durand-Claye.

ON the 8th inst. the English delegates gathered in Section 5, in the hope that the question of quarantine would be reopened. Dr. Proust, however, was absent, and as he was the author of the report on the subject it was thought advisable to await his arrival. The section therefore proceeded to discuss the subject of vaccination. Dr. Villemin related that in the department of France where he lived vaccination was performed only once a year, and those who were not present on that occasion could not be vaccinated. A Mexican delegate spoke in favour of compulsory vaccination, and Dr. Treile lamented that, even in an intelligent centre like Paris, the population displayed the greatest indifference to the subject. He described how at Fribourg small-pox had reappeared since the abolition of compulsory vaccination in that town. An American delegate said that from time to time he instituted a house-to-house visitation, so as to know if all the inhabitants had been vaccinated. Dr. Arnoult, military inspector, claimed that to the army belonged the honour of having given the example to the French nation of the advantages that accrue from vaccination and revaccination. But their difficulty was to contend against the non-vaccinated civil population. In the Second Army Corps some soldiers under his care contracted small-pox at the Amiens Hospital. To avoid resistance he had sought to popularise vaccination from the calf. Dr. Proust, who by this time had arrived, said that the German army was only really exempt from small-pox when the civil population had been vaccinated and revaccinated. He preferred vaccination from the calf to the use of lymph from even the healthiest-looking children. Dr. Felix said that in Roumania vaccination, but not revaccination, was obligatory. They had not succeeded, even with the aid of the law, in vaccinating everybody till vaccination from the calf was introduced, then the popular resistance ceased. Dr. Janssen said that in Belgium vaccination was not obligatory by law, but was insisted upon in every school, in every public service and institution, and was so admirably organised that there were very few Belgians who were not properly vaccinated. The subject was then allowed to drop.

Mr. Adolphe Smith, on behalf of the English delegates, now rose to inquire whether the Inspector-General of the French Sanitary Services, Dr. Proust, understood that the section had not adopted the fourth clause of the conclusions of the report on sanitary works in seaport towns. The first three clauses had been carried unanimously, but as nothing had been said about quarantine, Mr. Smith, in common with several others, imagined that the vote did not apply to the fourth clause. The English delegates, especially at this late hour, were not in the least desirous of opening up the question of quarantine, and if Dr. Proust would concur in the opinion that the fourth clause had not been put to the meeting the subject need not be further discussed.

Dr. Proust, however, did not agree to this. He was under the impression, on the contrary, that the fourth clause had been adopted; but, if there were any objection to this clause, he was quite willing that the matter should be investigated. Dr. V. Vignard, formerly director of the sanitary service of the Lower Danube, rose and fully endorsed what Mr. Adolphe Smith had said. He had also voted for the first three clauses, which alone had been discussed, and not for the fourth, to which he was absolutely opposed. A conversation thereupon arose between Dr. Proust and Dr. Vignard, which continued till they were called to order and each party asked to make a statement. Dr. Vignard consequently delivered an energetic speech. The resolution stated "that it was only when the ports presented a soil unsuitable for the penetration of morbid exotic germs that the last quarantine checks could be abolished;" but what criteria were they to show that the soil could not harbour germs? A port was never quite purified. People talked of the "rendering healthy" (the *assainissement*) of England as if it was something similar to the washing of a plate—an operation which, when once performed, was evident to all eyes. But there were English delegates present who could testify that this was not the case. In spite of the great works accomplished in England, much remained to be done, and even in London there were many plague spots. He complained that he did not know what was going on in the sanitary services of France, and required a large publicity and public control with regard to the quarantine observations imposed by the French port authorities. He had noted with pain and surprise a remark in Dr. Brouardel's opening speech, to the effect that the treason of one guardian of a lazaret had cost Spain in 1884–85 no less than 200,000 lives. What was this system which by the momentary neglect of one out of many thousand guardians could bring about the loss of 200,000 lives? He agreed with quarantine as defined by Fodéré in 1815. It meant a rope. The difficulty was to prove its utility or its inutility; for if we pointed to failure in one country, others would point to success in other countries. History, however, was against quarantine; for in the fifteenth century it had been properly and rigorously applied. In those days it was said that for a quarantine three things were necessary—money, force, and the hangman. A quarantine enforced, as in the past, by sentences of death was logical; but as we were not prepared, and as it was absolutely unpractical, to return to these barbarous practices, it was illogical, vexatious, and useless to maintain the fiction of quarantine. It was not till the Government of England had officially proclaimed that quarantines were useless that real sanitary improvements were accomplished. The great fear entertained in England of cholera facilitated the execution of sanitary works. What was the use of asking municipalities to vote large sums for sanitary works if they were told at the same time that they would be protected by the imposition of quarantines which would cost them nothing?

Dr. Proust, in reply, protested that he had no desire to

Digitized by Google

revive the old quarantine methods. They were willing to give every facility to companies whose ships were well managed. As for publishing the details of what was done, that would be very uninteresting reading, but whenever anything of interest happened it was at once communicated to the press. The term quarantine was subject to misinterpretation; the abolition of this word had been proposed at the Rome Conference. We need only take precautions against the cholera, the plague, and the yellow fever. These diseases came from such a distance that precautions were possible. First, all consuls in the different distant ports could telegraph information; then the journey took from fifteen to twenty days, which was in itself a period of observation; and, finally, the greater part of the ships had to pass through the Suez Canal, where timely information could be obtained, and, if necessary, the ships detained before they entered the Mediterranean. This detention was proposed at the Rome Conference, and approved by the twenty-two or twenty-three nationalities officially represented. England and India alone voted against the proposal. If a ship had a disinfecting stove on board, a good doctor, and no dangerous case had recently occurred, then they would give free pratique. But if there had been cases of cholera on board two or three days previously, then the ship should be detained. Practically, he had found on inquiry that such detention would have the effect of stopping four or five English ships for four or five days each year. There was a great difference between this and the quarantines described and denounced by Dr. Vignard. Besides, England had herself just sent the ship *Neva* into quarantine for sixteen days at Southampton. (This assertion greatly surprised the English delegation, who had certainly not heard of the circumstance.) Dr. Proust went on to give further explanation, which tended to reduce the meaning of the word "quarantine" to method of observation and of disinfection, very different from what is generally understood by the term. Dr. Treile approved of quarantines, and maintained that they had saved Algeria from cholera in 1884.

Mr. Adolphe Smith rose to explain that the point at issue was the actual wording of the resolution. Dr. Proust might attenuate the meaning of the word quarantine in a very satisfactory manner, but this would have no effect whatever with the outside public. Hundreds of newspapers would publish the text of the resolution, but would not know, or would not have space to mention, the explanations given in the section. The point was not what Dr. Proust might mean, but what the resolution meant; and the resolution undoubtedly meant that quarantine might be imposed even in the most salubrious of ports, for there was no port in the world which could be described as absolutely incapable of harbouring imported germs of disease. Dr. Proust and several French delegates protested that they did not interpret the resolution in such a literal sense; but Mr. Smith, supported by the English delegates, persisted that this was the view the outside public, unenlightened by the discussions of the section, would take of the matter, and that therefore he should be obliged to press the question to a division. Dr. Proust now, however, offered to withdraw the word "quarantine," and put "restrictive measures" in its stead. This, when taken in connexion with the general tone of the discussion, was considered satisfactory, and it leaves for future congresses to discuss what restrictive measures may be imposed as a substitute for the old-fashioned quarantines. An amicable compromise being thus effected, the section adjourned without a division. The following is the text of the original resolution and the amendment proposed, and accepted by Dr. Proust and the entire section:—"C'est seulement alors que les ports présentent un terrain réfractaire à la pénétration des germs morbides exotiques on pourra supprimer complètement les dernières entraves quarantenaires." Altered to "les dernières mesures restrictives."

On Friday morning the members of the International Congress of Hygiene went to the Exhibition and examined the sanitary apparatus displayed there. In the afternoon, in Section 5, M. Maignen read a lengthy paper on Water Filtration. He suggested, as a test, that water should be mixed with a known microbe, and a guinea-pig or rabbit inoculated with the water. Another rabbit should be inoculated with the same water after filtration. If the former died, and the other did not, this might be taken as a proof that the filter was good. Dr. Macé had made experiments with the germ of anthrax in this manner, and found it did not pass through the "filtre rapide." The filter was equally efficacious in preventing the passage of metallic poisons, copper, lead, &c., in solution. Some little discussion ensued, during which preference for the porcelain filter was expressed by some of the speakers, though it works much more slowly. M. Maignen was thanked for his interesting communication, and the President of the section concluded by saying that filters were always excellent at first; the difficulty was to discover how long they would last.

Dr. Girard (Rheims) opened a discussion on the Supervision of Meat, urging that diseased meat should be cremated; that this was the best means of preventing its being surreptitiously sold. He further urged that the rules for supervision should be the same in rural as in town districts. This proposal was adopted by the section.

After a few words about syrup of glucose, Dr. A. J. Martin's report on River Pollution was taken into consideration. There has been a great amount of legislation on this question in France. There were ordinances issued in August, 1669; in February, 1773; in June, 1777; and July, 1782. All these had the force of law, and all declared that refuse, filth, manure, &c., should not be thrown into rivers. These old laws were recently invoked (July 24th, 1875) by a Ministerial decision. Then there is the law of Oct. 10th, 1810, on manufactories &c. The law of April 15th, 1859, inflicts a fine of from 30 francs to 300 francs and imprisonment of from one to three months on those who throw into rivers chemicals that kill the fish. A Ministerial circular, dated July 31st, 1882, forbids pits or porous wells, by which subsoil waters can be polluted with the residue of factories. Nevertheless, all these enactments require to be codified, and, above all, more strictly applied. Consequently, Dr. Martin concluded that industrial residue of a dangerous nature should not be allowed to flow into a river or an underground watercourse. This can only be allowed when the residue has been so treated as to deprive it of all toxic, putrid, dangerous, or any other sort of matter that can alter the natural quality of the river water. The purification of industrial waters or residue must be rendered compulsory, and executed according to approved methods. The purification by irrigation is the most perfect means of treating the waste water from mills &c. containing organic matter. This must sometimes be preceded by chemical and mechanical processes, to render such waters fit for agricultural purposes. These conclusions were adopted, but a very lengthy discussion ensued as to who should be responsible for the application of such a law. If a manufacturer refused to purify his residue, should the State do the work for him and charge him with the cost? If so, what method would the State apply? Perhaps some antiquated expensive method—in a word, the State might blunder and put the manufacturer to unnecessary expense. As it was, many manufacturers had actually made money in seeking to prevent water pollution, for this had led to the discovery of advantageous methods of utilising waste. M. L. Faucher, civil engineer, member of the Central Council of Hygiene in the department of the Nord, related that river pollution had produced typhoid epidemics in his district. Each manufacturer, however, denied that the waste was the cause, because they only partially polluted the rivers. It was as if one man had a pistol, another some powder, and a third a bullet, and each declared he could not possibly do any harm. Yet it was only necessary for the three to come together to be able to kill some one. This is exactly what happened in the river with the waste from factories, and now that it had been stopped in his district typhoid fever had been stamped out. It was ultimately decided that the authorities ought to carry out the necessary works if the manufacturers persistently refused to do so themselves.

In Section 4, on Saturday morning, Madame Tkatcheff read a most interesting and carefully prepared paper on the Condition of the Working Classes in Russia. Irrespective of Siberia and Poland, she said there were about 932,000 operatives employed in the mills and factories of Russia. The way a considerable proportion of these workers were recruited had a great influence on public health. Many of them were agriculturists, who, being unable to earn enough to live, came to the industrial centres and worked in factories from September to February. They had no homes in those industrial centres, but slept very often in the factory itself, in the midst of the machinery, or in a sort of dormitory provided for them just above the works, and separated from the works only by a rude wooden floor,

Digitized by Google

through which all the bad odours passed. Here the workers lay down on wooden shelves. They slept in their clothes, and at best had a little sacking. The shelves were placed one above the other, so that sometimes there was only a hundred cubic feet of space per person. All the inspectors appointed by Government to inquire into these questions had complained of the dirt, overcrowding, and the promiscuity, for men and women often slept in the same dormitory. The hours of work varied from twelve to fourteen, and the food was altogether insufficient. The clothing was also of the poorest description. It was rare that a man could afford to wear leather boots, but contented himself with wrapping his feet in paper and rags and thrusting them in woollen shoes. Shirts were considered a vain luxury, and but for the sheep's skins, worn with the wool inside, the people would die of cold. This sort of life soon destroyed all sense of self-respect, and fearful immorality was the result. The migrations of villagers into towns for a short time each year had brought back syphilis to the villages, and there were some villages in Russia where every single inhabitant was syphilitic. In some departments 10 per cent. of the recruits were syphilitic. There was but one redeeming feature: the Russian, however poor, always insisted on having a bath. He would as soon go without his food as go without his weekly bath. There were no statistics to show what was the mortality of the Russian working-class population, but the general mortality was sufficiently significant; it was 17 per 1000 in Sweden, 24 per 1000 in France, and 36 8 per 1000 in Russia. Out of 1000 deaths, the proportion of infants under one year was 113 in Norway, 190 in England, 216 in France, and 313 in Russia. The mortality among adults was equally high in Russia, and taking the deaths occurring at ages varying from thirty to sixty years the comparison was as the figures 11 for Norway, 13 for France, and 19·4 for Russia. Up to the year 1882 children five years old worked in factories. These children were sometimes syphilitic as well as the victims of alcoholism. There were no regulations to prevent the explosions of boilers, nothing to hinder accidents with machinery. Women had to suckle their babies in the passages of the factories; and as for benefit societies or anything of that description, it would be a mockery to speak of saving to people who are driven by starvation to put up with so fearful an existence. In the match trade 75 per cent. of the workers were children, and they employed white phosphorus. Yet there were men and women in Russia well acquainted with the progress accomplished in Europe, and some attempt had been made to imitate the good example. In 1882 a law was enacted forbidding the employment of children under twelve years of age, and limiting their work up to the age of fifteen to eight hours—that is, four hours, then an interval of three hours' schooling, and then four hours' more work. The law also forbids the employment of children in thirty-six different and dangerous industries, and this is three more than is the rule in most European States. Another law enacted in 1885 forbids night work for women and children in weaving and spinning mills, but this law is as yet only applied in three centres. There is also organised, under the Ministry of Finance, a system of factory inspection. Russia for this purpose is divided into fifty-nine industrial departments; and as each head inspector receives 5000 roubles and the sub-inspectors 3000 roubles, it is anticipated that they will be able to render good service, and that it will not be easy to bribe them to neglect their duties. There is also a law to the effect that where there are more than a hundred persons employed in a factory medical attendance should be provided; but it is physically impossible to apply this law, for there are only 18,000 doctors in the whole of Russia. Consequently many factories have no medical attendant, and the lack of proper care in sickness is another cause of the high rate of mortality.

Madame Tkatcheff's paper, of which this is but a brief and incomplete summary, produced a deep effect. After a few questions had been put, Mr. Adolphe Smith rose, and urged the section not to rest satisfied with congratulating Madame Tkatcheff. She had given them a graphic and appalling picture of widespread suffering and human degradation. It was no use holding congresses if they did not exercise their undoubted influence to put an end to such abominations. He would suggest that the Russian delegation might prepare a report on the effect of the recent Russian legislation, and on the actual condition of the working classes in that country. This report could be presented to the London Congress, and followed by a resolution worded in the manner which the Russian delegates might think would have the best effect in Russia. Such a resolution, put to the entire London Congress, and adopted unanimously, as there was every reason to hope it would be, could not but have effect. There was no Government so deaf as not to hear the voice of a congress representing the best elements of sanitary progress in modern civilisation. In any case, it was impossible to sit still and make no effort to remedy a state of affairs which was a disgrace to our common humanity. The use of international congresses was precisely to bring international pressure to bear where there was a weak point in the armour with which civilisation clothed herself to war against disease and premature death. He therefore moved the following resolution: "That this section invites the Russian delegates to submit to the International Congress of Hygiene, in London, in 1891, a report on the results of the new laws for the protection of labour, and a resolution for the amelioration of the material condition of the working classes in Russia."

This speech and proposal were warmly cheered, and the resolution was unanimously carried.

Dr. Dargelos read a paper on a method for rendering felt hat manufactories less unwholesome. M. Fisher brought forward some proposals for disinfecting night soil on its passage to the sewers, and M. Maignen an invention for purifying sewer water and extracting therefrom the solid residue, the ammonia, &c. The section, on the strength of these two papers, was asked to vote a resolution regretting that the proposed credit of 200,000 francs for experiments in this direction had been struck out of the French budget. Mr. Smith objected, on the ground that the French budget did not concern an international congress, but only the principle at stake, and he thought we should all agree that all the Governments, and not one single Government, should be more liberal in such matters. The utilisation of sewage was a problem that might necessitate expensive experiments, and the States of Europe and America should, by small subventions, encourage such experimental research. A resolution in this wider sense was thereupon unanimously adopted, and the section adjourned.

On Friday afternoon some sections met at two o'clock, but at four o'clock all the sections met together in the grand amphitheatre for the final sitting. Dr. Brouardel, as President of the Congress, explained that the sections had passed a number of resolutions, that the subjects to be discussed in each section had been fully announced beforehand, and therefore each member of the Congress had enjoyed the opportunity either of supporting or combating any one of the proposals brought forward. Under these circumstances they might conclude that what the sections had done had been well done, and now he would ask the Congress to approve by vote, and if possible without discussion, the decisions of the sections. Dr. Martin then commenced to read upwards of fifty resolutions. Dr. Brouardel soon discovered that a large number of these resolutions dwelt exclusively with French questions, and therefore did not put them to the Congress, but referred them back to the French committee. Most of the other resolutions of a general character were confirmed by a show of hands, though now and then there were a few opposing votes, and often a great number of abstentions. The fact was that many of the subjects were entirely new to a large number of the members, who had not been able to attend more than one section at a time. Still, it was too late for discussion, and many things were allowed to pass which will require revision. Many of the resolutions thus confirmed have already been given in describing the work of the sections. To these I might add a resolution, very warmly applauded, demanding that an address be forwarded to M. de Freycinet, Minister of War, congratulating him on his recent measures on sanitation in the army. Other resolutions demanded—a permanent inquiry into the cause of excessive infant mortality, a stricter control over midwives, the teaching of hygiene in schools, the publication of methods of water analysis, the creation of bureaux of hygiene and municipal laboratories in all centres of population, new laws enabling municipalities to compel householders to adopt the town water-supply, the abolition of all laws preventing cremation, the encouragement of cremation on battle-fields, the better inspection of phtrmacies, &c.

The reading of these resolutions having taken up con-

Digitized by Google

siderable time, the concluding ceremony had to be proceeded with very promptly, and Dr. Brouardel spoke for only a few moments. He announced that the next Congress would be held in London during the first week of August, 1891. The work of organisation had already commenced, and the subjects to be discussed would probably be known in about six months time. He thanked his colleagues from abroad for the excellent support they had given the Congress, and hoped the harmony which had prevailed during the week among the members of the Congress would continue to reign amongst the nations represented.

Dr. Roth, on behalf of the foreign delegates, wished to thank the President and the organising committee for all they had done.

Senator Dr. Pacchiotti, in an enthusiastic speech, reproved the President for qualifying him as a foreigner. "The President," he exclaimed, "salutes the foreigners, but there are none in France. We are all at home in France. Here we meet each other, we live close to each other, we learn to love each other, we talk on the same subjects, we pass the same resolutions; we are not foreigners, we are brothers."

Mr. Shirley Murphy, in the name of the English delegation, rose to thank the French organisers of the Congress for the admirable reception they had prepared. He hoped to demonstrate the gratitude felt by the care they would take in providing hospitable entertainment in London. The cause they had at heart merited the support of all civilised nations. He only regretted that London was not a beautiful city like Paris, and that London did not possess a Brouardel. Nevertheless, he cordially urged all present to accept the invitation and meet again in England, and therefore he did not say *adieu*, but *au revoir*.

Mr. Shirley Murphy was loudly cheered, and the Congress was declared closed amidst cries of "*à Londres!*"

Though the official work of the Congress was thus brought to an end, some two hundred members met again on the following Sunday morning, and, led by M. Bechmann, engineer-in-chief of Paris, visited the palatial sewers that run from the Place de la Madeleine to the Châtelet. In barges and in a sort of tramway they travelled through underground Paris. The sewers were illuminated by many lamps and also by electricity. The barges were supplied with cushioned seats, the ladies came in elegant toilettes, and, so that they should not soil their dresses, the steps down into the sewers were carpeted. As an engineering feat these palatial sewers, as they have been so justly described, are certainly most remarkable, and well worth a visit. From the Châtelet the members of the Congress were conveyed in comfortable brakes to the sewage farm of Gennevillier. At Clichy they stopped to see the pumping machines, which lift a third of the sewage and send it over the river in an iron pipe to Gennevillier, where it is used to irrigate 750 hectares of market gardens. The remainder will in course of time be sent to Archères and to Méry. In the meanwhile, two-thirds of the Paris sewage still fall into the Seine at Asnières, and the members of the Congress were able to witness how it fouls the waters of the river. They then went over the sewage farm, admired the vegetables, ate some of the fruit, and drank the beautiful clear water derived from the sewage of Paris. It contained, they were assured, a smaller number of microbes than the best spring water, the Vannes water, supplied to the town of Paris. The Congress now proceeded to enjoy the excellent lunch provided by the town of Paris at a restaurant in the little village of Gennevillier. The toasts were preceded by speeches of a particularly earnest and hearty character. Dr. Martin, as president, proposed that a crown composed of flowers from the sewage farm of Gennevillier should be deposited by the Congress on the grave of M. Alfred Durand-Claye, the author of the scheme of which they had admired the result. He recalled that when, in 1878, Durand-Claye had visited Gennevillier, he had been mobbed by the inhabitants; now he was the hero of the place.

M. Emile Trélat, who could scarce control his emotion, drank to the memory of his old friend. Durand-Claye had been an eminent engineer, he had distinguished himself at college everywhere; but what made him really great was the whole-hearted manner with which he had given himself up to his work. Around them at Gennevillier, every hod of earth, every flower, breathed his name. A man with two hearts—a heart in France and a heart in his native Italy, Pacchiotti had proposed that a monument should be raised in honour of Durand-Claye. As a Frenchman, he could but blush that a Frenchman had not first made the suggestion; but while blushing, he gladly followed the example set by his excellent Italian friend. M. Deligny, Municipal Councillor, who had worked fifteen years with M. Durand-Claye, spoke a few affectionate words in his memory; and then the Mayor of Gennevillier, in the name of the inhabitants, desired to associate himself with the project, and promised a free grant of land for the monument.

M. Bechmann, M. Durand-Claye's successor, and Dr. Henriot, Mayor of Rheims, having spoken, there were loud cries for Dr. Bourneville, who in the National Assembly had carried the Bill which legalised these irrigation works, and whose admirable report on "l'Utilisation agricole des eaux d'égout de Paris" should be studied by all who are interested in the subject. Dr. Bourneville, in his speech, paid a handsome tribute to the various international congresses of hygiene. It was their debates, their decisions, which had strengthened his hands and enabled him to obtain the sanction of the French Assembly. M. Durand-Claye had collected a splendid library on sanitary questions, and proposed to leave it to the Museum of Hygiene which he hoped the Municipality of Paris would soon be able to create, and he called upon M. Deligny to press the matter forward.

M. Bonkowsky Bey, chemist to His Majesty the Sultan, in a few well-turned sentences proposed that the name of the ten agriculturists who first consented to utilise the Paris sewage water at Gennevillier should have their names engraved on Durand-Claye's monument. Delegates from Mexico, Brazil, and Egypt having also expressed their sympathy, Mr. Adolphe Smith was again selected as spokesman on behalf of England and America. In the name of these nations he desired to participate in the centenary celebrations of 1789, a date to be ever associated with the spread throughout the world of those principles of freedom which were the basis of true scientific research and knowledge. As representing the most liberal nations of the civilised world, he hoped America and England would always remain united with France in their forward march. He claimed for these countries the full right to participate in the honours to be rendered to the memory of Durand-Claye. He challenged the French right to monopolise this memory. Durand-Claye was a glorious example of the international character of sanitary science. He had never paused at a frontier line, but studied hygiene with equal assiduity in England, Holland, Belgium, even in Germany, availing himself of all the good ideas he could find in all countries. That library which he had so generously left to the town would be found to be an international library; and Paris was an international town, and hygienists of all countries meant to avail themselves of Durand-Claye's experience, and while inspiring themselves by his great works, claimed their right to contribute to the homage that would so justly be rendered to his memory. This speech was enthusiastically received. Dr. John H. Rauch, medical officer of health of Chicago, confirmed briefly in English the sentiments expressed, and promised to raise a subscription for the monument in America. Several hundred francs were at once collected among the guests, who, though they had started at nine in the morning, did not get back to Paris till five in the afternoon. Still the Congress was not quite over, for the next evening a hundred members, principally the foreign delegates, were entertained at a brilliant reception given in their honour at the Ministry of the Interior, by the Minister, M. Constant.

Thus at last was this most animated and successful Congress terminated. I have given a very imperfect, incomplete account of the proceedings, but perhaps have said enough to show the interest and importance of such congresses. Several subjects, notably the ventilation and heating of houses, so originally and ably treated by M. Emile Trélat and M. Somasco, I must leave for a separate study, and will attempt to describe the theories enunciated when dealing with the exhibits on these questions. But for a full account of the Congress it is best to wait till the official report, which will constitute a large and handsome volume, is published. This will probably be done at an early date, and will be sent gratuitously to all the members of the Congress. Those who were not members will probably be able to obtain the report by applying to the Secretary General of the Société de Médecine Publique et Hygiène Professionnelle, 28, Rue Serpente, Paris.

Paris, Aug. 19th.

THE NEW SYDENHAM SOCIETY.

THE thirty-first annual meeting of the new Sydenham Society was held at Leeds on Friday, Aug. 16th, Dr. Robert Barnes in the chair. The report, as below, was read and adopted, as was also the balance-sheet.

During the year which has just closed the following works were issued:—Second and concluding volume of Spiegelberg's Midwifery; the fifteenth fasciculus of the Lexicon of Medical Terms; the first volume of Cohnheim's Lectures on General Pathology; the first volume of Henoch's Lectures on Diseases of Children. For the year just commenced (1889) two works are already in the members' hands; these are—the seventh fasciculus of the Atlas of Pathology, comprising Diseases of the Gall-bladder, Calculi, &c., with one plate, illustrating Osteitis Deformans; the third volume of Charcot's Lectures on Diseases of the Nervous System.

Respecting the Lexicon of Medical Terms, the Council is glad to know that its value is being more and more widely appreciated, and that new members are not rarely attracted by the wish to obtain it. The editors have now completed considerably more than half of their onerous task, and although their work does not proceed so rapidly as could be wished, its progress is steady. Respecting the excellence of their work, the Council believes there is but one opinion, and that nothing has been omitted likely to hasten its conclusion may readily be believed.

The following works will be ready within the next six months, and the date of their issue will depend entirely upon the funds placed at the Council's disposal:—The second volume of Henoch's Lectures on Diseases of Children; the second volume of Cohnheim's Lectures on General Pathology; the sixteenth and seventeenth fasciculi of the Lexicon of Medical Terms; Flügge's Treatise on Micro-parasites. The Council wishes it to be clearly understood by local secretaries and members generally that the question as to the number of works to be issued in the current year rests with themselves. The works mentioned are almost finished, but most of them must of necessity be held over for another year unless subscriptions now due are paid up promptly, and a certain number of new members enlisted. It may be understood in a general way that the addition of £500 to the Society's income carries for all members an additional volume for the year. If, then, that number of new members can be added for 1889, or half that number for the two years 1888 and 1889, an additional volume will be given. In this matter the Council cannot but feel that it has discharged its share of duty to the Society, for the works in question are in readiness.

The receipts for the year amounted to £1887 11*s.* 1*d.*, and the expenditure to £1799 13*s.* 7*d.* Dr. W. T. Gairdner was elected President for the ensuing year, and Dr. Sedgwick Saunders and Mr. Jonathan Hutchinson were re-elected Treasurer and Secretary respectively.

OUR ARMY.

FROM the "Preliminary Return of the British Army," prepared by the Adjutant-General, we learn that the average strength of officers in 1888 was 7822, and of warrant officers, non-commissioned officers, and men 203,783. Of the latter, 103,140 were serving at home and 100,643 abroad. The deaths reported among them during the year were 1852 and the number discharged as invalids 2750, being respectively in the ratio of 9·11 and 13·53 per 1000 of strength. There were 8409 men, or 41·36 per 1000, transferred to the Army Reserve. There were 47,503 recruits inspected, of whom 14,973 were rejected before, and 1616 after, attestation, making a total of 16,589, or 349 per 1000 examined. Of the total enlisted, 25,156 ultimately joined, being in the proportion of 529 per 1000. Of the recruits who joined, 17,129, or 682 per 1000, were under twenty years of age. This is unsatisfactory, as it shows an increase in the proportion under twenty compared with 1887, when it was 642, and with 1886, when it was 636 per 1000. Of the men serving at home on January 1st, 1889, 234 per 1000 were under twenty years of age. Arranged by nationalities, of every 10,000 serving, 7580 were English, 908 Scotch, 1379 Irish, 128 colonials, and 5 foreigners. The average strength of the Army Reserve in 1888 was 54,395 non-commissioned officers and men, of whom 51,174 were in the first class and 3221 in the second. The deaths among the former were 303 and among the latter 61, being respectively in the ratio of 5·92 and 18·94 per 1000 of strength. The difference in the death-rate was doubtless the result of the different age distribution of the two classes; in the first class almost all the men were under forty, and three-fifths of them were under thirty, while in the second class they were nearly all above forty years of age. The average strength of the Militia, exclusive of the permanent staff, was 110,441, and among them the deaths reported were 408, or 3·69 per 1000, but this is probably understated, as a considerable number were struck off the strength as absentees, some of them in all likelihood being deaths. The Militia Reserve averaged 30,503, with 113 deaths reported, or 3·70 per 1000, but they also had a number struck off as deserters and absentees. The average strength of the Yeomanry Cavalry was 11,081, and they lost 81 by death, being 5·32 per 1000. The difference in the death-rate of Militia and Yeomanry Cavalry may be in a considerable degree a result of age, as in the latter the proportion of men above thirty was 375 per 1000 of strength, while in the former it was only 260. There was also a marked difference in the numbers struck off for absence, amounting in the Militia to 79·6, while in the Yeomanry Cavalry they were only 19·2 per 1000. The average strength of the Volunteers during the year was 227,253, and the deaths reported were 746, or 3·28 per 1000; but it is probable that the omission to report deaths has been even greater than in the Militia. The Volunteers are comparatively young, the proportion above thirty years of age being only 221 per 1000. We have prepared from the report the following table, showing the relative ages of the men forming the home force of the kingdom:—

	AGE.		
	Under 20.	20 to 29.	30 and upwards.
Army at home	233·8	636·1	130·1
Militia	279·9	459·6	260·5
Yeomanry Cavalry ..	63·5	561·8	374·7
Volunteers	218·7	560·5	220·8
Army Reserve	—	572·5	427·5
Militia Reserve	43·8	654·0	302·2

From this it appears that the Militia has the highest proportion of lads under twenty, and that the Regular Army has the smallest proportion of men of thirty and upwards.

IRISH LUNATIC ASYLUMS.

THE thirty-eighth report on the District, Criminal, and Private Lunatic Asylums in Ireland has just been issued. The report has been prepared by Dr. Nugent, the other inspector having retired on pension. The continued and progressive decrease of the population of this country, to the extent of 776,000 individuals within the present decade, and of whom no less than 78,600 emigrated last year, has materially influenced, as regards Ireland, the proportion between the sane and insane. The accepted ratio of mental disease, as judged by reliable data in the United Kingdom, had hitherto been estimated at about 2·86 cases in every 10,000 inhabitants; that proportion has been undergoing a progressive and marked change in Ireland, through emigration and from the fact that the mentally affected of all ages are abandoned by their departing relatives, while the indigent and those in the humbler walks of life are relegated to poorhouses or public asylums. The result is that about 36 to 10,000 would at present represent in Ireland the proportion of the insane to the sane. Of the 15,685 patients mentally affected on Jan. 1st last, 10,825 were located in district asylums, and 4083 in workhouses. As contrasted with the number of insane on Jan. 1st, 1888, there has been an increase of 442. The total number under treatment for the past year in district asylums was 13,320, of whom 1207 were discharged recovered, 356 improved, 144 incurable, and 786 died. The mor-

Digitized by Google

tality in Irish asylums, as represented in a long series of annual returns, has been uniformly low in proportion to the daily number of their inmates. Last year it was only 7⅛ per cent., or one and a half under the average. Of the 786 deaths, 287 were due to thoracic affections, 205 to cerebral and cerebro-spinal affections, 120 to debility and old age, and 78 to abdominal affections. In a few asylums dysentery prevailed for some time, especially at the Richmond and Carlow institutions. In the former there were 96 cases, of which 25 proved fatal; and in the latter 11 died out of 61. The sewerage of the Richmond was, on examination, found to be imperfect, and the main conduits to the river choked up, so that an extensive system of sanitary improvements was undertaken, at an estimated cost of £15,000, and is already far advanced. In reference to the physical causes of the mental disease in the inmates of asylums, 265 were attributed to intemperance and irregular living, 274 to cerebral disease, and 323 to bodily injuries and disorders, out of a total of 977 from physical causes. Of the total number (2821) admitted into district asylums during the past year, 868 were married, 1717 single, 134 widowers or widows, and in 102 instances the social condition was not known. That the number of single should nearly be double that of the married is contrary to what is observed in other countries. In consequence of the excess of admissions over the available accommodation, day-rooms and corridors were not unfrequently converted into dormitories, in some asylums to between a fifth and a sixth of their legitimate extent. The institutions most affected were the Richmond, Cork, and Belfast; in the first there is an excess of about 240 inmates, and in the others of over 130. The total insane in workhouses amounted to 4083: the idiot class was composed of 1903 individuals, 360 being epileptic; and the demented to 2180, of whom 389 were also epileptics. The expenditure in district asylums for the past year was £219,585, equal to a capitation scale of £20 10*s.* 10*d.*, or a slight decrease as compared with 1887.

THE BRITISH DENTAL ASSOCIATION.

THIS Association commenced its tenth annual meeting on Tuesday in the Pavilion at Brighton.

Mr. Daniel Corbett (Dublin), who occupied the presidential chair last year, being unable to visit Brighton, the chair was occupied by Mr. J. Smith Turner.

Mr. F. Canton made a good report as to finances, declaring a satisfactory balance at the bankers.

Mr. Morton Smale, in reading the report of the executive for the past year, said: "The prosecution of offenders against the Dentists Act as hitherto conducted, although eminently successful from a legal point of view, has not produced that impression on the public generally which is so very desirable; but it is hoped in the immediate future by concerted action to not only punish offenders but also to impress the public and enlighten them how to distinguish between the regular practitioner and the quack or charlatan. Three prosecutions have been successfully carried out during the past year. It is hoped during the coming year to deal with those who, unable to call themselves dentists or dental surgeons, evade the Act by styling their premises 'Dental Institutes,' 'Dentoriums,' &c." He said that the members numbered 763, against 710 last year, showing a net gain of 53. The Association had lost by death two members; one of these, Mr. Spence Bate, F.R.S., had a reputation as a scientist that extended far beyond the confines of the dental profession.

Sir John Tomes, Sir Edwin Saunders, and Mr. John Smith (Edinburgh), were elected Vice-Presidents of the Association.

It was decided to hold the next annual meeting at Exeter, Mr. Browne-Mason of that city being chosen President-elect.

Mr. S. LEE RYMER, J.P., the President for the year, then delivered his inaugural address, in which, after welcoming the Association to Brighton and thanking the members for the honour of his election, he proceeded to review hopefully the probabilities of prolonging the average of human life to seventy years—the aids of science, including dentistry, being employed towards this end.

The remainder of the day was occupied by the reading and discussing several important papers on Anæsthetics, their nature and action and methods of administration.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

THIS Society held its summer meeting on Thursday, Aug. 15th, in the theatre of the Medical School, Leeds, and during the meeting of the British Medical Association in that city, Mr. F. Treves, a member of the Council, took the chair. There was a good attendance of members and visitors, and a number of interesting matters were brought before the meeting. Dr. Ambrose succeeded, by following the nerve trunks, in ascertaining that an extra lumbar vertebra belonged to the sacrum and not to the dorsal region, Drs. Griffith and Oliver, having observed that the distribution of herpes zoster seemed irreconcilable with current accounts of the anatomy of the spinal nerves, were led to investigate their anatomy. They showed to the satisfaction of the meeting that the dorsal branches of the spinal nerves were distributed to the skin very much lower than is supposed, and that they ran downwards for some distance in the substance of the muscles of the back. Three gentlemen also showed a very interesting series of specimens and frozen sections from the Leeds Museum, including a patent parumbilical vein, an anomalous round ligament of the liver, feet with six toes, and frozen sections of the pelvis. Dr. R. W. Reid also sent some rare specimens of cervical ribs, a fifth lumbar vertebra with a suture in the neural arch, between the upper and lower articular facets, and the calvaria of a tumbler from Sir Astley Cooper's collection. Messrs. Lockwood and Withers showed an unusual right aortic arch, which, besides showing the usual condition, had persistence of a part of the second left arch, which gave off the left subclavian artery. By far the most interesting exhibits were those of Professor Alexander Fraser, who showed a very large series of photographs of anatomy, histology, and embryology. His composite photographs were greatly admired, as were also his photographs of brains. The same anatomist also described some bodies like Paccinian which he had found in the thyroid gland, and, in giving the details of his work on the spinal cords of a number of rodents, said that he found that the pyramidal tract ran in the posterior columns of the cord, and not as others had described. Both as regards the attendance of members and visitors and the value of the work placed before it the meeting was most satisfactory.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 6016 births and 3518 deaths were registered during the week ending Aug. 17th. The annual rate of mortality in these towns, which had declined from 21·0 to 18·8 per 1000 in the preceding three weeks, rose again to 19·2 last week. During the first seven weeks of the current quarter the death-rate in these towns averaged 20·0 per 1000, and was 0·4 below the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 9·0 in Derby, 15·9 in Bristol, 16·2 in Nottingham, and 16·6 in London. The rates in the other towns ranged upwards to 27·9 in Newcastle-upon-Tyne, 28·1 in Hull, 29·5 in Sunderland, and 42·6 in Preston. The deaths referred to the principal zymotic diseases in these towns, which had declined from 1018 to 785 in the preceding four weeks, rose again last week to 812; they included 555 from diarrhœa, 69 from measles, 54 from diphtheria, 53 from scarlet fever, 45 from whooping-cough, 36 from "fever" (principally enteric), and not one from small-pox. These zymotic diseases caused the lowest death-rates last week in Oldham, Huddersfield, and Bradford, and the highest rates in Hull, Plymouth, and Preston. The greatest mortality from diarrhœa occurred in Hull, Portsmouth, Birmingham, Leicester, and Preston; from measles in Hull, Halifax, and Preston; from scarlet fever in Plymouth; from whooping-cough in Birkenhead; and from "fever" in Preston. The deaths from diphtheria included 36 in London, 4 in Birmingham, 3 in Sheffield, and 2 in Liverpool. Small-pox caused no death in any of the twenty-eight great towns; and no small-pox patient was under treatment at the end of the week either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever

Digitized by Google

patients in the Metropolitan Asylum and the London Fever Hospitals at the end of last week was 822, against numbers increasing in the preceding seven weeks from 559 to 779; 90 cases were admitted to these hospitals during the week, against 124 and 98 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 182 and 149 in the preceding two weeks, rose again to 162 last week, but were 26 below the corrected average. The causes of 79, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Norwich, Wolverhampton, Blackburn, and Cardiff; the largest proportions of uncertified deaths were registered in Newcastle-upon-Tyne, Liverpool, Bristol, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased from 17·9 to 18·6 per 1000 in the preceding three weeks, declined again to 17·8 in the week ending August 17th; this rate was 1·4 below the mean rate during the same week in the twenty-eight large English towns. The rates in these Scotch towns ranged last week from 11·6 and 14·0 in Aberdeen and Greenock to 20·7 in Glasgow and 26·9 in Perth. The 455 deaths in the eight towns showed a decline of 20 from the number in the previous week, and included 43 which were referred to diarrhœa, 21 to whooping-cough, 10 to measles, 7 to diphtheria, 6 to "fever" (principally enteric), and not one either to small-pox or scarlet fever; in all, 87 deaths resulted from these principal zymotic diseases, against 77 and 107 in the preceding two weeks. These 87 deaths were equal to an annual rate of 3·4 per 1000, which was 1·0 below the mean rate from the same diseases in the twenty-eight English towns. The deaths referred to diarrhœa, which had been 39 and 57 in the previous two weeks, declined to 43 last week, but exceeded by 23 the number in the corresponding week of last year. The 21 fatal cases of whooping-cough showed a decline of 3 from the number in the preceding week, and included 12 in Glasgow, 4 in Paisley, and 3 in Dundee. The deaths from measles, which had been 8 and 10 in the previous two weeks, were again 10 last week, of which 4 occurred in Glasgow, 3 in Aberdeen, and 3 in Leith. The 7 fatal cases of diphtheria corresponded with the number in the preceding week, and included 3 in Edinburgh, 2 in Glasgow, and 2 in Dundee. The 6 deaths attributed to "fever" showed a decline of one from the number in the preceding week, and included 2 in Edinburgh. The deaths referred to the principal diseases of the respiratory organs, which had been 60 in each of the previous two weeks, were 57 last week, and corresponded with the number in the same week of last year. The causes of 36, or nearly 8 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·7 and 24·8 per 1000 in the preceding two weeks, declined to 24·4 in the week ending Aug. 17th. During the first seven weeks of the current quarter the death-rate in the city averaged 22·4 per 1000, the mean rate during the same period being 17·7 in London and 16·1 in Edinburgh. The 165 deaths in Dublin showed a decline of 3 from the number in the preceding week; they included 25 which were referred to diarrhœa, 4 to whooping-cough, 3 to "fever," 1 to measles, 1 to diphtheria, and not one either to small-pox or to scarlet fever. Thus the deaths from these principal zymotic diseases, which had been 15 and 25 in the previous two weeks, further rose to 34 last week; they were equal to an annual rate of 5·0 per 1000, the rate from the same diseases being 3·0 in London and 2·2 in Edinburgh. The deaths referred to diarrhœa, which had been 8 and 17 in the preceding two weeks, further rose to 25 last week. The four fatal cases of whooping-cough corresponded with the number in the previous week. The deaths from "fever" exceeded those recorded in any recent week, while those from measles showed a further decline. The deaths of infants showed a marked increase, while those of elderly persons were below those recorded in the preceding week. Three inquest cases and 4 deaths from violence were registered; and 40, or nearly one-fourth, of the deaths occurred in public institutions. The causes of 22, or more than 13 per cent., of the deaths in the city were not certified.

"Audi alteram partem."

VACCINATION AND INFANTILE SYPHILIS.

To the Editors of THE LANCET.

SIRS,—Returning with Dr. Creighton from his interesting excursus into the laws of evidence, the Maybrick trial, &c., to our starting-place, I have to point out that the subject of my letter was "the argument derivable from Scotch registration statistics regarding the relationship between vaccination and infantile syphilis, and Dr. Creighton's connexion therewith." He had stated that he had "established" the argument in question, and I showed, as I believe, that his assertion rested on very insufficient ground, and I further urged this as a warning to his readers—who might not be able, as I had been in this case, to turn to the original documents—of the too great facility with which it was possible for him to come to a finding on the subject. We seem to be at one as to what his ground actually was, and this being so, his reiteration of its sufficiency only of course emphasises my opinion that he is apt to build on too slender a foundation, and leaves the issue clear for those who care to judge. He states, quite truly, that in addition to the Scotch statistics, he had other reasons for his views on infantile syphilis. That goes without saying. It was not, however, with his other arguments that I elected to deal, but only with the particular statistical argument in question, and therefore I did not dream of inserting, as he thinks I should have done, a quotation as to his opinions on congenital syphilis.

Whether the indication which I gave would be provisional or permanent would of course depend on whether or not the reader would take the pains to extend his acquaintance with the subject, either through consulting the authorities at first hand, or, more easily though less satisfactorily, through such criticism as may appear in the *Edinburgh Medical Journal* or elsewhere. But, as we may take it for granted that many readers will do neither, then unquestionably I desired and do desire that, carrying away with them the fact that vaccination is opposed by one man of standing in the profession, they should at the same time carry away the other fact (as I hold it to be) that the man in question is liable to base his statements on insufficient evidence. This Dr. Creighton calls "a vague and comprehensive innuendo." The term does not seem to me to be applicable.

The Doctor mentions, as a difference between us, that while I had transcribed the Scotch figures into my book, he had transcribed them only into his note-book. That, I take it, was unfortunate, for though they owe much of their value to comparisons which he has not made—one being with English figures of which he was not cognisant,—if he had put even the Scotch figures into his book, they would have served in great measure to counteract the pageful of figures, constituting an oft-repeated argument against vaccination, which in his discussion of the matter he did insert. Indeed, it is not easy to see why, in his desire to protect vaccination from unjust assault, he should have omitted the former (as pedantic?), while he found a place not only for the latter, but for another table showing how the registrations from vaccinal erysipelas had increased during the past thirty years. On his part, as a defender of vaccination against the "alarmist teaching" of anti-vaccination writers[1] on this subject, the omission was surely a tactical blunder.

I am, Sirs, yours sincerely,

Aug. 19th, 1889. JOHN C. MCVAIL.

THE USE OF ROBURITE IN MINES.

To the Editors of THE LANCET.

SIRS,—I trust to your sense of fairness to allow me space to reply to an annotation under the above heading in your issue of July 20th.

1. In the first place, let us eliminate from consideration the unfortunate accident at Gathurst which you refer to "as proving beyond doubt that roburite is a very poisonous compound," since it had nothing whatever to do with the use of the explosive in mines. It was proved at the inquest that the poor man died from the effects upon a weak heart of getting into a closed shaft or

[1] THE LANCET, Dec. 1st, 1888.

Digitized by Google

funnel employed to carry off the fumes of di-nitro-benzol during the manufacture of roburite, for the purpose of cleaning it out, and doubtless he inhaled into his system a quantity of the finely divided substance. This ought, of course, never to have been allowed, as mechanical means can be used for the purpose, but it may be noted that other healthy men had repeatedly done the same without receiving any sensible harm. I have known a remarkably strong man die from inflammation of the lungs caused by inhaling the fumes of a pot of guncotton which "fumed off" during manufacture, yet I venture to say no one would characterise guncotton as "a very poisonous compound."

2. The report of the medical and chemical experts referred to by you was couched in the extremely cautious terms universally employed by such authorities, and yet was considered by Her Majesty's Mining Inspectors and the Home Office as favourable to the use of roburite. As reported in *The Times* of July 20th, the Home Secretary refers to it as follows:—"I am informed by the inspector that there is a growing use of roburite in the Lancashire collieries. It is a useful explosive, and practically safe for use in fiery mines. I gather from newspaper reports that its use has been condemned by miners as injurious to health. An inquiry was recently held into this matter by a committee of experts on which the Miners' Federation was represented, and their conclusion was, that if proper care is exercised by managers, shot-firers, and colliers, the use of roburite will not add to the harmful conditions under which the miner works." Now, the appointment of the committee in question arose chiefly out of the abortive strike at the Park-lane Colliery of the Garswood Coal and Iron Company, referred to by you; but you were not aware, probably, that this strike was led by the secretary of the Lancashire Miners' Confederation, and that, in addition to himself, two members of the miners' committee which condemned roburite were concerned in the said strike. I will only add that the most powerful defence of roburite which I have seen appeared in the columns of the *Wigan Observer*, from the pen of an independent working miner, who considered safety from the danger of explosion as the very foremost requisite of an explosive for coal mining.

3. In laying such stress upon the injurious effects of the fumes of fired roburite, the Lancashire Miners' Confederation have chosen to attack that explosive upon its strongest side, for there is abundant evidence that its products of explosion are less noxious than those of any other high explosive in ordinary use. Testimonials to this effect can be seen from many colliery managers in the Lancashire district, as well as from other parts of the country. While carrying out an extended series of experiments, on the first introduction of roburite, in the great Yorkshire and Durham coal districts, many shots were fired in distant galleries of deep mines under the superintendence of my colleague Admiral Colomb and of myself. I can testify that after taking up a position as near to the coal face as was consistent with safety, I invariably rushed up the moment the shot was fired, and never experienced the least inconvenience from the fumes, although I was at the time suffering from a bronchial affection. But we have far stronger testimony on this point; two experimenters employed by the Roburite Company have fired many thousands of shots under all possible conditions, and both of them are perfectly healthy. One of these men in the early part of the present year fired away in one series of experiments 401b. of roburite in eighty charges of various weights, in an unventilated tunnel, spending twenty-three consecutive hours in the tunnel without being the worse for the fumes. The experts' report shows that, besides an amount of carbon di-oxide not sensibly greater than that often inhaled in a London fog, there is present a small quantity of carbonic oxide, which they consider arises from the action of di-oxide upon the carbon of the coal, and which would therefore be generated by the use in a coal mine of any other explosive substance.

4. In the peroration of their report the Miners' Committee draw a harrowing picture of the results of having placed in their hands a substitute for gunpowder which will "slowly destroy our health, poison our whole system, and eventually send us to a premature grave." Certainly, the fumes will not shorten their lives, and why the shot-firers should handle the naked roburite I cannot conceive, since it is enclosed in air-tight and waterproof cartridges of various sizes. A drop of nitro-glycerine on the skin will cause a bad headache, and no one would needlessly handle naked dynamite; but I deny that, unless carelessly taken into the system with food, or absorbed through abrasions of the skin, handling even naked roburite will poison any one; I have made experiments with the granulated substance taken from a glass bottle, and manipulated it with my fingers a great many times without any ill effects whatever. The peculiar smell of roburite arises from a mere trace of mono-nitro-benzol always present with the mass of the chloro-di-nitro-benzol, which latter is not volatile, and, as everybody knows, the ammonium nitrate is harmless.

5. In conclusion, while expressing my surprise that the writer of your article should have followed the miners' committee in misreading the report of the experts, I would point out that to condemn roburite as poisonous and injurious to health, if used with ordinary care, is to condemn the whole class of modern high explosives, of which di-nitro-benzol is a chief ingredient, as securite, bellite, and others, whereas a scientific commission, appointed by the French Government, which has been carrying on exhaustive experiments during the last two years, has reported most highly upon this class of explosives, as eminently adapted for use in fiery mines. An elaborate and valuable report upon this subject, addressed to the Minister of Public Works, may be seen in a comparatively recent number of the *Journal Officiel* of the French Republic.—I am, Sirs, your obedient servant,

W. H. WARDELL, Major-General, R.A.,
Author of articles "Explosives," &c., in last edition of the "Encyclopædia Britannica," and the "War Office Handbook of Gunpowder and Guncotton."

Brighton, August 20th, 1889.

THE NOTIFICATION OF INFECTIOUS DISEASES BILL.

To the Editors of THE LANCET.

SIRS,—The contention of Dr. McLintock of Bradford is that also of Mr. Crosse of Norwich, and of Dr. Whitelegge, late of Nottingham—namely, that under the single or householder system of notification, although the local Act directs the medical man to hand the certificate to the householder or person in charge of the patient, the medical man takes the duty of notifying upon himself in almost every instance, just as if he were under the dual system. This is very remarkable, and indicates an ignorance of the law obtaining in the several towns that one can scarcely credit. But quite possibly the assumption has arisen in the minds of the medical officers of health from the fact that the only signature appearing is the doctor's, and that the address of the sanitary authority is printed in readiness, either on the back of the form of certificate or on an envelope provided for the purpose. Be this as it may, the practitioners of Norwich, Nottingham, and Bradford are under no compulsion to notify directly, and there are no penalties attached to an omission to do so on their part, although they are compelled to certify. The rights of both householder and practitioner are in those towns protected by law, and if either of them casts his right away he has no one to blame but himself. But it is easy to conjecture that in numberless instances the householder would acquiesce in the document being sent by the doctor direct. And this only shows how needless is the dual system, especially as statistics give the preference to the other. I am very pleased to see Dr. Collins's letter, and, in common with the majority of the profession, am deeply grateful to you for your untiring support of our cause.

I am, Sirs, yours faithfully,

Kingston-on-Thames, Aug. 17th, 1889. D. BIDDLE.

To the Editors of THE LANCET.

SIRS,—Dr. W. J. Collins's criticisms on the Notification Bill conveyed in his letter in the present issue of THE LANCET appear to centre chiefly on the compulsory system the Bill will introduce, and the restrictions thereby imposed upon the liberty of the subject. The system, like almost everything else that is new, may cause a little friction at first, a little annoyance to certain general practitioners, and in a few instances even a little domestic unhappiness, which a voluntary notification from the heads of families would entirely do away with. Unfortunately, this much-to-be-desired consummation would be too much to expect, and it must be conceded that there will be, and has been, less concealment of infectious disease under compulsory notification than without it. As a practical hygienist himself,

Digitized by Google

Dr. Collins, with a full knowledge of the conditions under which the poorer classes of the community almost invariably live in crowded localities, and of the apparently hopeless task it is to instil into their minds the most elementary principles of the hygiene of the sick room and of the meaning of the word "cleanliness," will perhaps admit that, although the compulsory element in the Bill is not entirely free from objection, it will only press hardly on those who, either from ignorance or from selfishness, are apathetic as to the public health—the class precisely for which a little mild legislative interference with the liberty of the subject is so sorely needed. That the Bill as it stands is not absolutely perfect may be granted; that opinions vary as to the justice of requiring the practitioner to notify as well as to certify is also a fact; that young practitioners have, and will again, call measles scarlet fever is a matter of history. Surely Dr. Collins does not desire to delay the passing of the measure on grounds such as these; or even because Dr. John Harley has not yet obtained proof of the contagiousness of scarlet fever. The Bill is sound in principle, and should be loyally supported by all sanitarians and the profession generally—to the extent even of waiving, for once in a way, any individual pet theories of the spread and prevention of certain diseases,—and welcomed as a step in the direction of strengthening the hands of those doing battle in the cause of health. As an educational measure alone it will prove invaluable, inculcating upon the individual the obligations of citizenship. The beneficial effects of the system have been proved already in more than fifty towns and districts. The measure can scarcely be called ill-considered, and, if it does become law, will, after all, be optional outside the metropolis, instead of being universally compulsory.

I am, Sirs, yours truly,

E. J. LAWLESS, M.D. Brux., D.P.H. Lond.

London, Aug. 19th, 1889.

THE PROPHYLAXIS OF TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—On page 326 of THE LANCET of last week you publish some American rules as prophylactic against phthisis. Among other things, it is there stated that the room where the unfortunate patient lives and that in which he sleeps must be without curtains, or carpets, or rugs, or anything that is nice and cozy; and the sputum and the evacuations from the bowels are to be disinfected. And all this—I will not say what—you publish without note or comment. In opposition to these arbitrary, and in my judgment quite needless, precautions, seeing that it is still doubtful if phthisis is infectious at all in the ordinary sense of the term, will you kindly publish the fact so often stated, and as it would seem so generally ignored or overlooked, by our ardent theorists, that before the *bacillus* came to the front, or was even dreamt of, the Consumption Hospital at Brompton, without any precautions against infection whatever, showed as clean a bill of health amongst its staff of medical men, matron, and nurses, as any *non-special* hospital in the kingdom. Perhaps this fact may comfort some who have relatives or friends suffering from pulmonary consumption, and who may not care so to shut them out of society, and so to treat them, as laid down in the above-mentioned extraordinary rules.

I am, Sirs, yours obediently,

King's Lynn, Aug. 20th, 1889. WM. DALE, M.D. Lond.

*** Publication of the suggestions referred to does not imply approval, as our correspondent would have seen had he noted the remarks on this matter made in these columns in the preceding week. We agree with him as to the impracticability of these and many other proposals to treat phthisis as a contagious disease; but there is no disguising the fact that the opinion that it is communicable has been arrived at by many scientists in all parts of the world.—ED. L.

DIPHTHERIA AND ITS TREATMENT.

To the Editors of THE LANCET.

SIRS,—I have read with great interest Dr. May's letter in your issue of Aug. 17th under the above heading. I do not think he emphasises sufficiently the importance of frequent applications every three or four hours at least of the selected germicide to the affected parts, with removal at every application of as much membrane as possible. With regard to Dr. May's practice of administering an emetic or an aperient with the view of removing from the stomach and intestines the diphtheritic poison which may have lodged there, it is difficult to see how a single evacuation of their contents can be of any service at all. We know that the diphtheritic membrane is constantly re-forming, and that particles of it are constantly being swallowed by the patient along with his food or the saliva; one would require therefore continual emetics and aperients to keep the alimentary system free from the presence of the germs. I cannot agree with Dr. May that "tonics and stimulants in the early stage should not be given." One can lay down in diphtheria no such hard-and-fast line, for though I may have seen cases which required throughout little treatment save attention to general rules, I have carefully followed to its termination many a one in which a free and early exhibition of tonics and stimulants seemed obviously the rational treatment. I may say that I have found a solution of 1 in 1000 corrosive sublimate made up with glycerine and applied with a brush a most excellent throat application. Allow me to add that my experience has been gained in the Birmingham Children's Hospital, and that the results of the treatment there have always been very good.—Yours faithfully,

Linlithgow, Aug. 20th, 1889. THOS. HENDERSON, M.B.

THE GOVERNMENT AND PROFESSIONAL PENSIONS.

To the Editors of THE LANCET.

SIRS,—The Bill relating to Civil Service Pensions which is to be brought into the House of Commons aims a blow at all professional men who are engaged in the service of the Crown, and the fact of such a measure being introduced at the fag end of a Parliamentary session alone calls for the most uncompromising opposition to which a Bill can be subjected. Medical men, engineers, and other professional and scientific experts who have been engaged on a definite understanding as to pensions run grave risk of having the amount of their pensions lowered under this Bill. One proposal is to calculate the amount of pensions on a longer period of service than heretofore; another is to do away with the special allowances in case of abolition of office; and a still more important change is, in calculating pension allowances, to deprive professional men of the added number of years which were allowed them owing to the fact that they have had to spend many years in acquiring a profession before they were fitted to serve the State. Besides which, the age at which a professional man can enter the service of the State, taken together with compulsory retirement at sixty-five years, would prevent him, and him alone among civil servants, from ever attaining the two-thirds of his salary which constitutes full pension. Immediate steps should be taken to urge all members of Parliament to oppose the introduction of such a Bill at this season of the year; and all who are likely to be influenced by the proposal, either now, on promotion, or hereafter, should at once communicate with members of Parliament on the subject; appeal being especially made to members representing universities, and to members of the learned professions who are in the House of Commons.

I am, Sirs, yours obediently,

Aug. 20th, 1889. Q.

RESECTION OF LAMINÆ OF THE VERTEBRÆ.

To the Editors of THE LANCET.

SIRS,—Mr. Henry Thompson, in connexion with the report of a case at the Hull Infirmary, published in the last number of THE LANCET, refers to a case of paraplegia due to spinal disease, treated by resection of the laminæ of three vertebræ, under my care. I regret to state that the subsequent course of that case was not so satisfactory as I had hoped it would be. The boy progressed very well till he was attacked by diarrhœa, which was prevalent in the ward at the time, and he suffered very severely from it for some weeks in spite of remedies. On my return to town, after a month's absence, I found him much emaciated and extremely feeble. His chest trouble, which had apparently subsided before the onset of the diarrhœa, had also made considerable progress. He was sent home. I have not heard of him since.—Your obedient servant,

St. Thomas's-st., S.E., Aug. 17th, 1889. W. ARBUTHNOT LANE.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Maybrick Trial.

IT is only natural that the *cause célèbre* which has attracted so much attention throughout the length and breadth of the land should have been the absorbing topic of conversation in medical and lay circles in the neighbourhood where it occurred, and in the city where the case was tried. The Crown Court, though probably one of the largest in the kingdom, was far too small for the demands made upon it. This court has witnessed several memorable trials. In 1860 Winslow was tried for the murder of a widow named James by poisoning her with antimony. It was only too probably a case of wholesale poisoning, but evidence was excluded which would now have been admitted, and what has generally been regarded as a great miscarriage of justice took place. In 1884 the two notorious women Flannigan and Higgins were tried, the trial lasting the whole of three days. More recently the no less notorious Mrs. Berry was tried and found guilty after four days' trial and sentenced to death. Still more recently came the case of Charles Parton, who caused the death of an elderly gentleman by putting chloral into his drink, and was found guilty, but was reprieved. The recent case, however, transcended in interest all these previous cases, the circumstances surrounding the case (as noted in THE LANCET of last week) combining to produce an effect never before seen. The crowds around St. George's Hall, in which are the Assize Courts, were enormous, requiring a large staff of police to prevent the hall being taken by storm. It may be confidently asserted that there never was a prosecution carried out with greater moderation and a fairness to the prisoner amounting to superstition. When Justice Stephen summed up, five days had been entirely taken up with the evidence on both sides and the three speeches of counsel. His charge to the jury occupied the whole eight hours of Tuesday, the 6th, and from 10 A.M. of Wednesday till 3 P.M., with, on each day, a short interval for lunch. This was considerably longer than the charge of the Lord Justice Clerk in Madeline Smith's case, which occupied seven days and a half, and little less long than that of Lord Campbell in Palmer's case, which latter occupied ten days in the evidence and speeches. To many of those who have watched the case from the first, and have been in a position to take a dispassionate view of it, the verdict of "Guilty" was a foregone conclusion.

"The Lancet' and the Local Press.

The leading article on the Maybrick case in last week's issue of THE LANCET appeared in the local evening papers of Thursday and the morning papers of Friday, and has given great satisfaction among the profession here. The excitement at first raised is calming down, and it is being made apparent that trial by mob would be a very sorry substitute for trial by jury.

A new Mortuary for Liverpool.

The Health Committee at their last meeting passed the plans for the new mortuary and post-mortem room which it is proposed to erect not far from the present structure. The plans were originally drawn up by Mr. G. F. Lyster, the dock engineer, on suggestions made by a sub-committee of the Liverpool Medical Institution, who also inspected the plans when completed, and suggested some improvements of a minor character. These plans have been revised and modified by the city engineer, and there is now every prospect that this greatly needed improvement will soon be effected. The importance of having a mortuary in accordance with modern requirements in such a city as Liverpool needs no advocacy.

City Churchyards and open Recreation Places.

Till within the last few years our city churchyards presented a miserable appearance, reminding one of Dickens's description of a London one: "Walled in by houses; overrun by grass and weeds, the growth of vegetation's death, not life; choked up with too much burying; fat with repleted appetite." Our city authorities deserve the greatest credit for the improvements they have effected and still are effecting. The various churchyards of St. Luke's, St. Peter's, St. Michael's, and St. James's have been converted from places like the above to pleasant recreation grounds, laid out in walks, with trees, shrubs, and flowers. Now St. John's churchyard, which, being close to St. George's Hall and our newest city buildings, was quite an eyesore, is being levelled and laid out at a considerable expense for another recreation ground. It occupies from one and a half to two acres in extent, and underneath are buried 81,000 bodies!

Liverpool, Aug. 19th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

A Munificent Bequest to Newcastle.

ONE of the poorer and most populated townships of Newcastle has just come in for the munificent bequest of £15,000 under the following circumstances:—In 1884 Mr. Lewis Thompson, a gentleman then resident in Newcastle, made a will, which has been proved, by which he leaves the income on annuity of this large sum to the overseers of the poor at Byker for the reduction of the poor-rate in the township. The conditions are very simple—viz., the overseers are to keep his father's tomb in good repair, and annually on the 17th day of August to place thereon a garland of the value of not less than 2*s*. If from any cause the guardians for three successive years fail to comply with these conditions, then the whole sum is to become the property of the British nation. It is to be hoped, however, that the memorial will be properly kept up and become of real benefit to the poorer ratepayers. Mr. Lewis Thompson, the generous donor, was educated for the medical profession, and studied in Newcastle and London. He never, I believe, practised on his own account, but assisted an eminent metropolitan surgeon. He afterwards turned his attention to scientific pursuits as applied to the arts and manufactures—such as gas and soap making. He was a copious contributor to such works as those of Drs. Ure, Lardner, and McCulloch, as well as to French and American encyclopædias. Although he wrote much, he seldom attached his name to what he wrote; and, further, with a view of preserving his anonymity, he recently destroyed some very valuable correspondence, under the belief that no one would be interested in it, and because some of the forecasts of his friends had not been verified by facts. All his labour in connexion with gas making was done gratuitously, and when some of the old gas companies proposed to remunerate him he returned the money.

Tyne Port Sanitary Authority.

At the last meeting of the Tyne Port Sanitary Authority it was reported that during the past month the following had been inspected: British steamers, 1380; British sailing vessels, 560; foreign steamers, 420; foreign sailing vessels, 433—making a total of 2793; while the total number of visits amounted to 3433. The number of emigrants that had arrived in the Tyne *en route* for America was 134, a decrease of 202 as compared with the previous months.

The Moors in the North of England.

I availed myself, after leaving the Leeds meeting, of the opportunity of taking a run over the Cleveland and North Yorkshire Moors—not as a sportsman, however, but as a traveller fond of the heather, and I can say I never saw it at the same time in such splendid bloom, the vast moorlands presenting a rich purple appearance, while a delightful aroma is wafted from it with every breeze.

Sunderland.

During the course of an inquest at Sunderland last week, one of the jurymen suggested that, as the doctor had not arrived, the medical fee should be divided among the jurymen. Mr. Coroner Graham said that if they waited a few weeks they would find that jurymen would be paid something: he could not say how much, but it was the intention of the County Council that some payment should be made to jurymen.—At the last meeting of the General Committee of the Sunderland Infirmary, a very interesting document referring to the railway ambulance movement and its progress, drawn up by Mr. J. C. Patterson, locomotive superintendent N.E.R., was read. It appears since the year 1872 611 cases have been conveyed by railway from the docks and east end of the town to the infirmary. There has been a gradual increase in these cases from twelve in 1872 to

Digitized by Google

seventy-six last year. The average time for conveyance of such cases to the infirmary is about seven minutes. The late Mr. James Hartley assisted very materially in the inception of the movement, and was deeply interested in its progress.—The present state of Sunderland is not keeping up to its late good health record, although there has been a decrease in the deaths from diarrhœa and in the infectious diseases notified. There are still seven cases of infectious disease in the hospital, five being small-pox.

The Health of Rothbury.

Some reports prejudicial to the fair fame of Rothbury at the present time as a health resort having appeared in some of our local papers, the three resident medical men, including the medical officer of health, are anxious to contradict the same. They say that during the spring there was a mild outbreak of scarlet fever, which subsided in May. Since then there have been only two cases, which they believe to have been imported. If so, it is very hard on this beautiful moorland health resort (where Lord Armstrong does the honours of Newcastle in his Cragside home) to have its fair name and season blighted by one or two sporadic cases of scarlet fever or any other disease. Great injustice is sometimes done to health resorts by the removal to them by persons and families from infected homes.

Newcastle-on-Tyne, Aug. 21st.

DUBLIN.

(FROM OUR OWN CORRESPONDENT.)

The Dublin Barracks.

As previously mentioned in these columns, two regiments removed from the Royal Barracks are at present under canvas in the Phœnix Park, and, despite the recent inclement weather, the health of the men is all that could be desired. At the commencement some tents were pitched on low-lying ground, and, being liable to be flooded during heavy rain, they have now been removed to higher ground; while, in order to protect the inmates, an extensive system of drainage has been carried out, the main trench, which is about eight inches deep, removing the rainfall to the rear of the camp. The water-supply is obtained from the adjoining magazine fort by means of metal pipes The Supplementary Army Estimate issued yesterday includes a sum of £20,000 to proceed further with the contract for the Grangegorman Barracks, and £7000 for certain alterations and reconstruction of the drainage of the Wellington Barracks.

Health of Ireland for June Quarter.

The births numbered 28,227, equal to 23·9, and the deaths 21,095, or 17·8 per 1000 inhabitants. The birth-rate for the quarter was 1·7 under the average rate for the corresponding quarter of the ten years 1879-88, while the deaths also show a decrease of 2·1 as compared with the same period. The general death-rate, being 10 per cent. below the average, must be regarded as satisfactory, while the rate represented by the total mortality from the principal zymotic diseases was also much below the average for the June quarter, and only slightly exceeds the rate for the second quarter of 1886, which was the lowest rate for any quarter recorded. Measles was very prevalent in a few districts, and whooping-cough in a larger number; but no other zymotic disease was prevalent throughout the country.

Alleged Insanitary Condition of Derry Prison.

Dr. Plunkett O'Farrell, medical member of the Irish Prisons Board, has inspected this prison along with the architect of the board, and it is stated that both gentlemen are thoroughly satisfied with its sanitary condition. The prison has had a remarkable immunity from fever and other contagious diseases for years past, a case of fever not having occurred for nearly ten years, while the ventilation and sanitation are regarded as perfect.

Mid-Antrim Coronership.

An election for a coroner for Mid-Antrim took place last week. There were two candidates, Mr. Caruth and Dr. McCaw, the former being successful by a large majority.

The Queen has conferred the order of K.C.B. on Dr. John Thomas Banks, one of the Physicians in Ordinary to Her Majesty in Ireland.

Dublin, Aug. 20th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Perils of the Telephone.

AT a recent meeting of the Société de Biologie Dr. Gellé read a note on the ill effects of audition by the telephone. He stated that he had on many occasions observed them. The first was that of a man of great intelligence, occupying a position which obliged him to listen sometimes almost incessantly to telephonic communications. The result was a state of nervous excitement, and hyperæsthesia of the hearing and of the ear itself to such a degree that the sounds caused vertigo and ringing in the ears, and led to the persistence of alarming vertiginous sensations. Complete rest was sufficient to remove these troubles. In another case a young *employée* in a large establishment, who had to attend to telephonic messages, felt her ear becoming rapidly weak, and it was soon the seat of noises and of a remarkable hyperæsthesia, and at the same time the hearing became painful. In this case also perfect rest and the cessation of her work almost completely cured her of these symptoms.

The Therapeutical Value of Inhibition.

It is already known that inhibition has been employed with a therapeutical object. Professor Brown-Séquard has made several interesting communications on this subject, and lately Dr. Dupuy brought to the notice of the Société de Biologie a new example in its support. He observed a case of lumbago disappear instantaneously by the injection of a few drops of chloroform in the thickness of the muscles of the sacro-lumbar region, and not under the skin, where the liquid would have produced an eschar. Dr. Dupuy remarked that this fact is most interesting, as it adduces a new argument in favour of this doctrine, which consists in considering the subcutaneous injections of morphia or of any other substance as acting principally, if not exclusively, by inhibition. The absorption, more or less rapid, of the medicament would then only have a secondary *rôle*.

Conjugal Diabetes.

Dr. Debove read a note at the Société Médicale des Hôpitaux on the coexistence of diabetes in the husband and the wife. Of fifty cases of diabetes, Dr. Debove observed five which existed simultaneously in the husband and in the wife. The same coincidence was established by Dr. Lecorché, who thought that this coincidence can only be explained in two ways: by the use of the same defective alimentation, or by the cares of life shared in common by husband and wife. Dr. Debove said that he could not accept this explanation, as women, from the nature of their habits and the exigencies of their sex, do not live exactly as their husbands. Hence it is that gouty couples are rare. He would therefore ask if diabetes were contagious; but for the present we must rest contented to register the fact. If new facts should show that conjugal diabetes is not a simple coincidence, it is only then one could propose a theory, which for the moment would be premature. Five or six other members also cited one or more cases in which they observed the coexistence of diabetes in the husband and wife.

Some Effects of the Paris Exhibition.

Of all the indispositions (and there are many) created by the Exhibition, the most curious is that which is caused by the firing of the cannon on the Eiffel tower. Every evening at 10 o'clock, when the gun is fired for the last time in the day, it is not unusual to see produced a sort of frenzy among the young female visitors to the Exhibition. Under the already strong impression produced by the illuminations, the luminous fountains, &c., when the gun is fired, they seemed to be seized with a veritable panic. It appears to them that a sudden catastrophe, such as a great fire, has taken place. Cries of admiration escape from some, and of terror from others, when fainting, attacks of hysteria, and of prostration occur. The subject has attracted the attention of Professor Charcot and other physicians.

The Tuberculosis Question.

There is prospect of a lengthy debate upon Tuberculosis at the Academy of Medicine arising out of the suggested "instructions" drawn up by the Standing Committee of the Congress on Tuberculosis. These were submitted to the

Digitized by Google

Academy, and exception was taken to some of the statements and proposals by MM. Germain Sée and Dujardin-Beaumetz. The preliminary discussion was concluded on the 13th inst. by M. Lancereaux, who laid more stress on the factor of predisposition than on the presence of the bacillus itself. M. Villemin, in reply, said everyone agreed as to the danger arising from the expectoration, a more fruitful source of the dissemination of the disease than the consumption of either milk or the flesh of tuberculous animals. The question was then referred to a commission consisting of MM. Verneuil, Sée, Cornil, and Dujardin-Beaumetz.

Paris, Aug. 20th.

THE SERVICES.

ARMY MEDICAL STAFF. — Surgeon Thomas Robert Lingard, M.B., from half pay, has been granted retired pay (dated Aug. 3rd, 1889).

ARMY MEDICAL RESERVE OF OFFICERS.—Surgeon Robt. Clark resigns his commission (dated Aug. 21st, 1889); Acting Surgeon Edward Thomas Crouch, 3rd Volunteer Battalion, the Hampshire Regiment, to be Surgeon, ranking as Captain (dated Aug. 21st, 1889).

INDIA OFFICE.—The Queen has approved of the following promotion:—Surgeon Charles Henry Beatson, of the Bengal Medical Establishment, to be Surgeon-Major (dated May 16th, 1889).

ADMIRALTY. — Surgeon Archibald McKinlay has been promoted to the rank of Staff Surgeon in Her Majesty's Fleet (dated March 31st, 1886).

VOLUNTEER CORPS.—*Artillery:* 2nd Volunteer (Essex) Brigade, Eastern Division, Royal Artillery: Acting Surgeon S. Evans resigns his appointment (dated Aug. 17th, 1889). 1st Volunteer (Devonshire) Brigade, Western Division, Royal Artillery: Surgeon and Surgeon-Major (ranking as Lieutenant-Colonel) G. Pycroft resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the Brigade on his retirement (dated Aug. 17th, 1889).—1st Renfrew and Dumbarton: Acting Surgeon W. R. Sewell, M.D., to be Surgeon (dated Aug. 17th, 1889).—*Rifle:* 2nd Volunteer Battalion, the Princess of Wales's Own (Yorkshire Regiment): Acting Surgeon J. F. Porter, M.D., to be Surgeon (dated Aug. 17th, 1889).—1st Volunteer Battalion, the Manchester Regiment: Surgeon J. A. Mackenzie, M.B., resigns his commission (dated Aug. 17th, 1889).—*Infantry* (Portsmouth Brigade): Surgeon and Surgeon-Major H. R. Smith, 3rd Volunteer Battalion, the Hampshire Regiment, to be Brigade Surgeon, ranking as Lieutenant-Colonel (dated Aug. 17th, 1889).

Medical News.

ACCORDING to a telegram from Copenhagen, an epidemic of diphtheria and typhus has broken out at Aarhuus, in Jutland. The authorities have ordered all the schools, public and private, to be closed.

THE ROYAL WEDDING.—In our enumeration, on page 208, of the list of members of the medical profession who were present by special invitation at the late Royal wedding, we inadvertently omitted the name of Mr. Arnold Royle, C.B.

A GENEROUS OFFER.—Alderman Pierce (the Mayor of Bangor) has signalised his year's mayoralty by an offer of £500 to form the nucleus of a fund towards the erection of a hospital for infectious diseases in that city. Bangor is not at present provided with such an institution.

ROYAL CORNWALL INFIRMARY.—The annual report of this infirmary for the past year records that 345 in-patients were admitted during the year, of whom 116 were medical cases and 229 surgical. There were 52 operations, 60 accident cases, 149 out-patient casualties, and 821 out-patients. Both the in- and out-patients had exceeded in number that of any previous year. The annual subscriptions continued to fall off, arising chiefly from deaths and removals; but the receipts and disbursements showed a balance in hand of £102 16*s.* 6*d.*

FOOTBALL ACCIDENT—ABERDEEN.—In a football contest on the 13th inst., between the A Team of the Orion Club and the Rangers, Thomas Irvine (of the Orion Club) came into violent collision with a Ranger player, Irvine sustaining a compound fracture of the right leg just above the ankle.

THE PLAGUE.—The *London Gazette* of the 20th inst. publishes a telegram from the British representative at Jeddah, dated Aug. 15th, as follows: "Plague at Assyr has disappeared; slight cases continue in Holba and two other villages. Quarantine reduced to five days from to-day; cordon between Lith and Taith removed."

THE WATER-SUPPLY OF DARLINGTON.—The justice of the complaints of the inhabitants of Darlington as to the bad condition of their water-supply has been confirmed by a report of a joint committee of the Town Council and the Durham County Council, which has declared it to be proved that the waters of the Tees, from which the supply is taken, is polluted with sewage.

POLICE AMBULANCE CLASSES.—On Aug. 16th Mr. W. A. Tyssen Amherst, M.P., presented certificates on behalf of the St. John Ambulance Association to 146 police officers in the theatre of the Royal United Service Institution. The certificates presented on this occasion brought the total of police officers certificated by the Association in the metropolis to 2231, and the aggregate number of certificates granted to date to nearly 170,000.

WEST HAM HOSPITAL.—A hospital in this densely populated district has, after several years' endeavours, been erected. The need of such an institution is sorely felt, but it appears the opening must be delayed for want of funds for the requisite furnishing and the disbursement of the architect's and the builder's fees. The estimated cost of the institution, including furnishing, is £7961, and the amount raised is £5760. The deficit—£2200—necessarily compels the committee to defer the opening of the institution for the reception of patients until additional funds are forthcoming. The accommodation provided is twelve beds for men, twelve for women, four for boys, and four for girls.

OVERHEAD WIRES.—A set of regulations has been issued by the Board of Trade in regard to overhead wires for the supply of electricity. *Inter alia* no aerial conductor must be at a less height from the ground than 20ft., or, where it crosses a street, 30ft. Every aerial conductor is to be furnished with efficient lightning protectors of a pattern approved by the Board of Trade. There are minute regulations dealing with the insulation, the suspension of conductors, and the protection of telegraph and telephone wires, &c. Any failure to comply with the requirements of the Postmaster-General is to be considered a non-compliance with the regulations.

ANCOATS HOSPITAL AND DISPENSARY. — The sixty-first annual meeting was held at this institution on the 15th inst. Mr. James Jardine presided. The report referred to the erection of the new wing to the hospital, and to the variety and amount of cases, especially in accidents, treated in the past twelve months, the number being larger than that of any previous year. The treasurer's financial statement shows a small increase in the subscription list, and that £9893 9*s.* had been contributed towards the extension fund. The medical report states that the total number of patients had been 10,169 (including 511 cases attended by the honorary dentist); of these, no fewer than 4487 were accident cases. The home patients numbered 2373.

PROVINCIAL HOSPITAL SUNDAY AND SATURDAY COLLECTIONS.—The recent Dawlish Hospital Saturday collections on behalf of the Cottage Hospital realised £33 7*s.* 2*d.*—The Windsor Hospital Saturday collection on July 27th amounted to £100 9*s.* 1*d.*, an increase of £10 11*s.* 8*d.* on last year.—The committee of the Hoyland and District Hospital Sunday Festival, recently held, have handed £30 to the treasurer of the Beckett Hospital.—The Hertford Hospital Sunday collection this year produced, net, £107 14*s.* 5*d.*, of which £53 17*s.* 2*d.* was apportioned to the Hertford General Infirmary, and a like amount to the Herts Convalescent Home.—The annual parade of the Warminster Local Friendly Societies, in aid of the funds of the Warminster Cottage Hospital, was held on Sunday, the 18th inst., and produced upwards of £29.

Digitized by Google

THE MUZZLING ORDER.—As a result of this order, 1100 dogs have been received during the last few days into the Dogs' Home, Battersea.

DRAINAGE OF MARGATE.—It is understood that official sanction has been given to Mr. Baldwin Latham's scheme for the sewerage of Margate.

LEWES HOSPITAL AND INFIRMARY.—At the forty-second annual meeting of the governors of this institution it was announced that the last Hospital Sunday collection in aid of the funds of the institution amounted to £202 17*s.* 7*d.*, but the receipts still show a small deficiency. Mr. W. T. Martin was re-elected hon. surgeon-dentist.

THE MEASLES EPIDEMIC AT ABERDEEN. — The medical officer of health, Dr. Hay, in his July report, states significantly that the decrease in the measles epidemic has been found to be coincident with the advent of the school holidays. Such being the case, it is manifest that extra precautions should be taken at the close of the vacation.

ALLEGED SWEATING BY VESTRIES.—A conference was held at the Metropolitan Hall, Blackfriars-road, last week, to protest against the system of "sweating" adopted by a number of London vestries with respect to the women employed in the dust-sifting yards of the vestries and who only receive the wage of 7*s.* a week. It was stated at the meeting that women stood working all day up to their waists in dirt and filth. Resolutions were passed denouncing the system, and calling upon the Government to grant a Royal Commission to inquire into the question with a view to the scandal being suppressed. A committee to collect the necessary information was appointed and the conference adjourned.

THE CALEDONIAN MEDICAL SOCIETY.—This Society, the membership of which is rapidly increasing, held its ninth annual reunion in the Grand Hotel, Trafalgar-square, on the 16th inst., Wm. A. Macnaughton, M.A., M.D., the President of the Society, in the chair. The objects of the Society are for purposes of mutual support, and for the advancement of medical science among its members, who must be graduates of a British university, and have some connexion with the Highlands of Scotland. The following are the office-bearers for the ensuing year:—President: Allan Macfadyen, M.D., D.Sc. Vice-President: J. Duncan Greenlees, M.B. Secretary and Treasurer: T. F. Tannahill, M.B., Rochester. Editor of Journal: J. Macpherson, M.B., Larbert, Stirling, N.B.

BEQUESTS AND DONATIONS TO HOSPITALS.—The Dowager Countess of Kintore has subscribed £1000 to the Jubilee Fund for the extension of the Aberdeen Royal Infirmary.—The guardians of the City of London Union have voted a donation of £10 to the Infirmary at Bow.—The late Miss Harriet Barton Denton, of Bank Road, Bootle, has bequeathed £110 to the Bootle Borough Hospital.—Mr. Adam Geck, late of Chiswell Street, London, has left by his will £300 to the German Hospital, Dalston, and £100 to the City of London Hospital for Diseases of the Chest.—On Aug. 13th, delegates from the various friendly, benefit, and trade societies met at the Old Friends' Hall, Upper St. Martin's Lane, London, for the purpose of presenting £139 to the secretary of the Children's Hospital, Great Ormond Street, being the net result of a demonstration held on June 30th.—The proprietors of the *People's Friend*, Aberdeen, have handed to the directors of the Aberdeen Hospital for Sick Children the whole receipts of the recent National Wild Flower Exhibition, amounting to £160 18*s.* 11*d.*, making no deduction for expenses.

MEDICAL NOTES IN PARLIAMENT.

The Lunacy Laws.

IN the House of Lords on Thursday, the 15th inst., a Bill to consolidate the Lunacy Laws was brought in by the Lord Chancellor and read a first time.

A Court of Criminal Appeal.

Lord Fitzgerald raised the question of establishing a Court of Criminal Appeal, and asked the Government to consider the matter during the recess and present a measure to Parliament during next session to effect that object.—The Lord Chancellor, Lord Herschell, and Viscount Cross condemned Lord Fitzgerald's action in raising this question at the present time, when considerable excitement prevailed in connexion with a case that was occupying the public mind.—The Lord Chancellor said he would prefer not to discuss the subject now in reference to any future alteration in the law, and that was as satisfactory an answer as the noble lord was likely to get from the Government.—Lord Fitzgerald said that, in view of the unsatisfactory statement made by the Lord Chancellor, he would take upon himself the duty of introducing a Bill next session dealing with the question.

Poor Law Bill.

The report of amendments on this Bill was brought up and agreed to. The Bill contains provisions enabling the Metropolitan Asylums Board to receive into their asylums patients suffering from diphtheria, and to hire out the Board's ambulances for the conveyance of fever patients from one place to another. The Bill was subsequently read a third time and passed.

Civilian Doctors and Military Service.

In the House of Commons on Thursday, the 15th inst., Dr. Kenny asked the Secretary of State for War whether Dr. Richard Nicholls of Navan, who was for over seventeen years civil medical officer to the regular troops stationed in that town, and also for some years medical officer to the Meath Militia, had recently, under some new regulation, been deprived of those appointments without compensation.—In reply, Mr. E. Stanhope stated that Dr. Nicholls held no appointment. He was employed, as medical men were all over the kingdom, to attend at contract rates detachments of troops when no military medical officer should be present. A military medical officer having been stationed at Navan, the necessity for Dr. Nicholls's service ceased. It had always been a condition of the employment of a civilian medical practitioner that his employment might cease at any time without notice and without the creation of any claim to compensation.

Scotch Universities.

In Committee of Supply, on the vote to complete the sum of £16,888 for Scotch Universities, Mr. Hunter moved to reduce it by £1316, the amount proposed to be paid to the University Professors of Theology. At the Aberdeen University the education of about thirty divinity students was £62 a year each. The medical endowments were smaller than those for divinity, but the number of students in medicine was more than ten times the number of divinity students, while the cost was only £4 16*s.* per student. The University of Edinburgh had an income of £1944 for divinity, and the number of students was 107; while the endowments for medicine amounted to £1776, the number of medical students being 1879; so that the cost per medical student was 19*s.*, and for each divinity student £18 3*s.* Taking the whole of Scotland, the endowments for medicine amounted to £5800, and there were 3000 students, the cost being less than £2 per head. The endowments for divinity amounted to £7664, and the students numbered 278.—The Solicitor-General for Scotland replied, and the vote was carried on a division by 123 against 73.

Londonderry Gaol.

On Friday, the 16th, Mr. Balfour, in reply to Dr. Kenny, Mr. Sexton, and others, stated that the results now received of the special investigation made by the medical member of the General Prisons Board, showed that Londonderry Prison had for at least a period of twenty years enjoyed a remarkable immunity from the principal zymotic diseases. There had been no case of fever among the prisoners during that period, nor was there any now.

Unqualified Medical Practitioners.

Mr. Ritchie, replying to Mr. Causton, said that he had made inquiry of the Registrar-General, and was informed that the death of a child was registered on the certificate of a duly registered medical practitioner, who stated on his certificate that he had attended the child during its last illness, and that the cause of death was, to the best of his knowledge, "dentition convulsions." An inquest was held, and a verdict found that the cause of death was narcotic poisoning. The coroner requested the registrar to inform the Registrar-General that the practitioner had certified that he had attended the child, although he had, in fact, never seen it, the child having been attended by his unqualified assistant. The registrar had asked to be furnished with a copy of the depositions. He had not yet received them, and he had therefore at present no evidence on which to take action.

Contagious Diseases Act.

Mr. Cavendish-Bentinck asked whether there were any statistics from India as to the alleged increase of contagious disease in the Indian army since the repeal of the Contagious Diseases Act. — Mr. E. Stanhope, in reply, stated that, so far as the British troops were concerned, the admissions for venereal disease had risen from a yearly ratio of 323 per 1000 for the year 1887 to 560 per 1000 for the first four months of 1889.—In reply to a further question from Mr. Cavendish-Bentinck, Sir J. Gorst said that the Cantonment Bill contained provisions for mitigating the prevalence of all contagious diseases within cantonments, and regulations for that purpose were now under the consideration of the Government of India.

Hospitals in Ireland.

On Saturday, the 17th, in Committee of Supply, on the vote to complete the sum of £16,658 for hospitals and infirmaries in Ireland, Mr. Sexton promised the support of the Irish members if the Government would bring in a Bill embodying the recommendations of the Royal Commission in favour of capitalising the whole grant for hospitals in Ireland, and putting the control of the sum realised under a central body, which should distribute the income according to the number and value of the various hospitals.—Mr. Jackson, in reply, stated that such a Bill had been drafted, and he believed it was just about ready. He would endeavour, after what Mr. Sexton had said, to introduce it during the present session.

Lunatic Asylums in Ireland.

On Monday, the 19th, Mr. Balfour, in reply to Mr. O'Keefe, stated that the scheme for the nomination by the Irish Government of governors on the various boards of lunatic asylums in Ireland was now practically completed, and the names would shortly be published.

Typhoid Fever in the West-end.

On Tuesday, the 20th, in reply to the Marquis of Granby, Mr. Ritchie said his attention had been called to the outbreak of typhoid fever in the West-end of London, and especially in the parish of St. George, Hanover-square. He had been assured that the vestry of that parish had a constant staff of men flushing the sewers at a large cost, and that the London County Council also had a staff of flushers for the purpose of flushing their main sewer. He had also received a provisional report from Dr. Corfield, the medical officer of health of the parish, from which it appeared that the outbreak took place almost entirely in the Mayfair sub-district. The outbreak had been limited to fourteen houses, and was confined to residences of the better class; and from the uniformity in the date of the attacks and the fact that the sanitary arrangements of most of the houses where the cases occurred had been carefully carried out, Dr. Corfield had come to the conclusion that the outbreak was not due to any defect of sanitary arrangements, but to some temporary cause, which had apparently ceased to operate.

The Vaccination Acts.

In reply to Mr. Bradlaugh, Mr. Matthews promised to make inquiries into a case tried at Enfield, wherein the magistrates adjourned a summons for two months against a man who had failed to have his child vaccinated. The medical attendant swore in court that the child was not then fit, and would not be fit for at least a year, to be vaccinated. In default of the father finding sureties to appear in two months, he was committed to gaol.

Health of Prison Officials.

On the report of the vote for superannuation and retiring allowances, Sir G. Campbell called attention to the enormous number of prison officials who had retired on account of ill-health.—Mr. Jackson explained that the phrase "ill-health" in connexion with prison warders was different from what it would mean in the case of other Government servants. A prison warder had to be in very full physical vigour, having to take charge of men not always of the most orderly character. It was therefore perfectly within the proper meaning of ill-health when the doctor certified that the warder's physical vigour and capacity were not equal to the arduous duties he had to discharge.

METROPOLITAN ASYLUMS BOARD.

Return of Patients remaining in the several Fever Hospitals of the Board at midnight on August 20th, 1889.

Births, Marriages, and Deaths.

BIRTHS.

COCKEY.—On Aug. 11th, at Little Waltham, near Chelmsford, Essex, the wife of E. Percival Cockey, M.D. Lond., of a daughter.

DILL.—On Aug. 17th, at Brunswick-place, Brighton, the wife of John Gordon Dill, M.A., M.D., of a son.

GRACE.—On Aug. 15th, at Park House, Thornbury, Gloucestershire, the wife of Dr. Edward Mills Grace, Coroner for the Lower Division of Gloucestershire, of a son.

NICHOLLS.—On July 30th, at Dominica, West Indies, the wife of H. A. Alford Nicholls, M.D., F.L.S., of a daughter.

WELLS.—On Aug. 14th, at Belsize-park, N.W., the wife of Poulett Wells, M.B., of a daughter.

WILKINS.—On Aug. 19th, at Windsor-road, Ealing, W., the wife of H. G. G. Wilkins, L.R.C.P. Lond., M.R.C.S., of a daughter.

MARRIAGES.

BUCKMASTER—BROOKS.—On Aug. 14th, at Worsley, Lancashire, George Alfred Buckmaster, M.D., Oxford, to Amy Elizabeth Brooks, eldest daughter of the late Charles Brooks, of Chester and Newton.

DILLON—STRELLEY.—On Aug. 13th, at the Parish Church, Reynoldstone, Glamorganshire, Charles Frederick Dillon, M.B., fourth son of Charles Forbes Hodson Shaw-Mackenzie, D.L. & J.P., of Newhall, Ross-shire, to Ada Maud, third daughter of the late Richard Clayton Strelley, of Oakerthorpe, Derbyshire.

GARRY—ROBERTS.—On Aug. 17th, at Sydenham, T. Gerald Garry, M.D., M.Ch., &c., of Princes-road, Liverpool, to Bridget, only daughter of the late Edmund Cleaton, J.P., of Vaenor Park, Llanidloes, and widow of the late W. D. Roberts, of Princes-road, Liverpool, and Bodhyfryd, Llanrwst.

JOSEPH—DUDER.—On Aug. 17th, at St. Luke's Church, Little Bay Mines, Notre Dame Bay, Newfoundland, Louis Joseph, M.B., C.M., to Alice Jane Duder. (By cablegram.)

MILLS—MUDGE.—On Aug. 15th, at the Parish Church, St. Elwyn, Hayle, by the Rev. W. Horsburgh, B.A., Vicar, Joseph Mills, of 28, Queen Anne-street, W., younger son of the late Robert Mills, of West Court, Inkpen, Berks, to Mary, youngest daughter of James Mudge, of Bonaér, Hayle, Cornwall.

WIGHTWICK—D'ALTON.—On Aug. 14th, at St. James's Church, Spanish-place, London, Fallon Percy Wightwick, M.B., only son of William Wightwick, J.P., Hilden, Folkestone, to Helen D'Alton, only daughter of the late John Shea, J.P., Cork, Ireland.

DEATHS.

CHAMBERS.—On Aug. 15th, at Shrubs Hill House, Sunningdale, Thomas King Chambers, M.D., F.R.C.P., Honorary Physician to H.R.H. the Prince of Wales, aged 71.

CHEVALLIER.—On Aug. 21st, at Ipswich, Barrington Chevallier, M.B. Oxon., M.D., M.R.C.P. Lond., Medical Superintendent of the Borough Asylum.

COMBE.—On Aug. 15th, at Holly House, North Walsham, Lancelot Orloff, second son of Orloff Combe, M.D.

CUMBERBATCH.—On Aug. 18th, suddenly, on board the yacht *Evangeline*, at Salen, Loch Sunart, Argyllshire, Lawrence Trent Cumberbatch, M.D., of Cadogan-place.

TAYLOR.—On Aug. 17th, at Nottingham, Henry Taylor, M.R.C.S., L.S.A., aged 76.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

FIELD, EDGAR A. H., L.D.S. Eng., has been appointed House Surgeon to the National Dental Hospital, Great Portland-street, W.

GILL, JOHN, L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer of Guilsfield District, Llanfyllin Union.

KELLETT, R. G., L.K.Q.C.P., L.R.C.S. Irel., has been reappointed Medical Officer of No. 1 District, Halstead Union.

MALET, HENRY, M.B., B.S., M.D. Dub., has been reappointed Medical Officer of Health of the Borough of Wolverhampton.

WHEELER, THOMAS, M.R.C.S., L.S.A., has been reappointed Medical Officer of Health, Bexley Union District.

WILKINSON, ARTHUR T., B.A., B.Sc., M.D. Lond., M.R.C.P. Lond., has been appointed Honorary Physician to the Ancoats Hospital, Manchester.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

BIRMINGHAM MEDICAL AID ASSOCIATION (Secretary, Westminster-chambers, Corporation-street, Birmingham).—Several additional Medical Officers in the borough and suburbs.

BOROUGH HOSPITAL, Birkenhead.—Junior House Surgeon. Salary £60, with board, lodging, and washing, also fees for notifying infectious cases. No wine or beer.

CITY ASYLUM, Birmingham.—Resident Clinical Assistant. Board, lodging, and washing provided, but no salary.

KINGSTON UNION (Offices: St. James's-road, Kingston-on-Thames).—District Medical Officer and Public Vaccinator for the Parish of Teddington. Commencing salary £80 per annum, in addition to extra medical fees for operations, amputations, and to the payment for quinine, cod-liver oil, and linseed meal, at cost price.

METROPOLITAN ASYLUMS BOARD (Offices: Norfolk House, Norfolk-st., Strand, W.C.)—Assistant Medical Officer, at the Eastern Fever Hospital, The Grove, Homerton, E.—Salary £15 per month, with board, furnished apartments, and washing.

NORTH LONDON CONSUMPTION HOSPITAL, Hampstead, N.W.—Resident Medical Officer. Honorarium £40 a year, with board, rooms, &c.

ROTHERHAM HOSPITAL.—Assistant House Surgeon. In lieu of salary, rooms, commons, and washing provided in the hospital.

STAMFORD, RUTLAND, AND GENERAL INFIRMARY.—House Surgeon and Secretary. Salary £100 a year, with board, lodging, and washing.

SWANSEA HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with board, furnished apartments, coals, gas, laundress, and attendance.

VICTORIA INFIRMARY, Glasgow.—Superintendent and Resident Medical Officer. Salary £125 per annum, with apartments and board.

WALLASEY DISPENSARY (Honorary Secretary, Elm Mount, Penkett-road, Liscard, Cheshire).—House Surgeon. Salary £110 per annum, with furnished apartments, coals, and gas.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE STUDENTS' NUMBER OF "THE LANCET" will be published on Saturday, September 7th. Those gentlemen holding official situations connected with medical institutions in the United Kingdom who have not yet forwarded the necessary information to our Office for publication in that number are earnestly requested to send it *without the delay of a single post.*

MALCOLM MORRIS INDEMNITY FUND.—EIGHTH LIST.

THE following additional subscriptions to the above fund have been received:—

Amount previously acknowledged ..	..	£458	0	0	F. Swinford Edwards, Esq.	£1	1	0
Dr. Percy Boulton	..	2	2	0	A. Napper, Esq.	1	1	0
Dr. Bowles ..	..	1	1	0	Dr. A. Garrod Thomas ..	1	1	0
Dr. Anthony Corley	..	1	1	0	Dr. Frazer	0	10	6
					Johnson Herbert, Esq. ..	0	10	6

Quien Sabe.—Severe symptoms have been noted amongst those engaged in the manufacture of benzine. Usually these consist of mental disturbance and uncertain gait. Delirium and loss of consciousness have also been observed. Several references to the subject will be found in Neale's Medical Digest.

Mr. W. Stevens is referred to a general notice at the head of this column.

VOLUNTEER AMBULANCE WORK.

To the Editors of THE LANCET.

SIRS,—I wish again to call the attention of the Volunteer Medical Service in the metropolis to a sum of £108 8s. 8d. which was handed over in June, 1887, to the Volunteer Medical Association by the Volunteer Ambulance Department, so ably conducted by Lieut. Andrew Maclure of the London Scottish R.V. This money has been placed under control of a joint committee representing the Volunteer Medical Association and the College of State Medicine. Two years have now elapsed, and the regimental surgeons and stretcher-bearers who subscribed to this fund are desirous to know when it is to be devoted to the purpose for which it was intended. It has been suggested that a challenge shield should be provided, and that it should be annually competed for by a detachment of each battalion. Would it not be better to hand over the sum to the Lord Mayor's Volunteer Patriotic Fund?

I am, Sirs, your obedient servant,

R. R. SLEMAN,

Ambulance Sergeant 20th Middlesex (Artists) R.V.; Hon. Sec. Volunteer Ambulance School of Instruction.

Gracechurch-st., E.C., Aug. 16th, 1889.

A HISTORICO-MEDICAL COINCIDENCE.

IN Rome, where the Sacred Way descends into the Forum, stands the interesting old church dedicated to SS. Cosmas and Damianus, two Christian physicians who for their services and sufferings in Arabia were canonised by the Pope. Damianus, or, as he is called for brevity's sake, Damian, became a power in Italy, where more than one house of prayer was reared in his honour, notably that one in the Umbrian hills. It was there that S. Francis of Assisi devoted himself to the spiritual life, and in a special manner to the cure of leprosy, a disease which by that time (the latter half of the twelfth century) had been introduced by the Crusaders from the East into all the countries washed by the Mediterranean. A ritual was compiled to celebrate with awful solemnity the isolation of the leper from his fellow-Christians—"a pathetic and melancholy service, in which the sternest interdict was softened by words of consolation and pity." Moved by their forlorn condition, S. Francis became the constant associate of the leprous and the inmate of their asylum at Assisi, where he washed their feet and dressed their sores, to which, indeed, in one case he applied his lips with such effect that the poor leper instantly became whole. So, at least, says S. Bonaventura. But the interesting point is this: that his care and cure of these victims to a loathsome malady was practised "sub invocatione Sancti Damiani" (under the invocation of S. Damian), a saint who six centuries thereafter was to find a counterpart in a Belgian priest of almost identical name—the Père Damien, whose noble life and death in the leper island of Molokai will never fade from the annals of his church, or, indeed, from the history of the world. The Vatican, it is understood, has taken the preliminary steps towards the canonisation of this true martyr in the service of mankind, and though the prescriptive period required for admission into the saintly calendar will not expire till well on into the twentieth century, there may be those now living who will survive to witness the Church of Rome's invocation of S. Damienus, closely allied in merit as in name with that other S. Damianus, who inspired S. Francis to his life of philanthropic self-sacrifice.

G., M.R.C.S.—Our correspondent should apply to the Secretary of the Medico-Psychological Association, Dr. Fletcher Beach, Darenth Asylum, Dartford, Kent.

Toothache should be guided by the advice of a qualified dentist.

TETANUS AFTER PARTURITION.

To the Editors of THE LANCET.

SIRS,—In the interesting communication in your last issue by Mr. H. Peacock on a case of tetanus occurring ten days after delivery, I notice that the writer states that he could not find any reference in old or modern works on obstetric medicine to tetanus following delivery. If, however, your correspondent would refer to Dr. Milne's Manual of the Principles and Practice of Midwifery, page 442, he will find therein a good account of tetanus in the puerperal state. The author gives details of a case as narrated by Dr. Craig of Edinburgh, which appears to be very similar to Mr. Peacock's case. It is fortunate that this terrible disease is so seldom developed, as treatment seems to have little or no effect upon it. There is a field open here to investigation, both as to its pathology and treatment.

I am, Sirs, yours faithfully,

JOHN COCHRANE, L.R.C.P & S.Ed.

Medical Officer of the Parish of Strath.

Broadford, Skye, Aug. 19th, 1889.

TOXIC PROPERTIES OF "CHICHA," A SOUTH AMERICAN DRINK.

THE *Anales de la Instrucción Publica en la Republica de Colombia* contain an interesting account of the effects produced by over-indulgence in a certain popular drink called "chicha," which is prepared by the fermentation of malted maize, with the addition of the leaves of the primum payaca, or "sandino," as it is called in the country. This beverage, when taken in excess, produces a feeling of extreme weariness, rendering the patients totally unfit to follow any kind of employment. There is also observed a loss of the power of coördination, which may make it possible on a cursory inspection to mistake the case for one of locomotor ataxia or spasmodic tabes; but "chichinism" can be distinguished from these conditions by making the patient shut his eyes and stand or walk, and touch his toes with his hands, all of which he is able to do. The course of chichinism, too, is quite short, and it may terminate in trophic changes and acute diffuse myelitis. Another symptom which is frequently observed is an erythema of the dorsum of the hand, similar to that seen in pellagra. Physiological experiments also show that the chicha has a special action on the skin; for frogs subjected to its influence present very decided changes of colour. With chronic alcoholism there is a good deal of affinity, but there does not seem to be any liability to excitement or hallucinations.

One who is nearly Bald should consult his usual medical attendant. We do not prescribe.

VENTILATION OF RUSSIAN RAILWAY CARRIAGES.

ACCORDING to Dr. Taratkevich (*St. Petersburg Dissertations*, 1888–89, No. 75), the ventilation arrangements of Russian railway carriages, especially those provided for third- and fourth-class passengers, leaves a good deal to be desired, the amount of carbonic acid being frequently ten times that which is compatible with health and comfort. The air was naturally found to be most vitiated at night and during the latter part of the day. Several of the estimations gave over 7 parts of carbonic acid per 1000 in the third and fourth classes. The highest amount found in a second-class carriage was 4·8 per 1000, and the highest found in a first-class carriage 3·41 per 1000. The relative humidity was usually very high at night in the third class, being frequently more than 85 per cent. The highest figures for the second and first classes were 87 and 75 respectively.

E. R.—The venture proposed is not in accordance with the spirit of the Pharmacy and Medical Acts. Clause 11 of the Pharmacy Act of 1852 says that "no person who is a member of the medical profession, or who is practising under right of a degree of any university, or under a diploma or licence of a medical or surgical corporate body, shall be entitled to be registered under this Act." The manager to be appointed, though qualified as a druggist, would only veil the real proprietor. We cannot say whether, legally considered, the real proprietors could be secured from liability. The arrangement contemplated is equally contrary to the bye-laws of the medical corporations. Thus the licentiate of the King and Queen's College of Physicians consents to give power, on being admitted, to the President and Fellows to withdraw his diploma if he shall after obtaining the diploma keep open shop for the sale of medicines.

J. S.—We cannot at present re-open the discussion.

"THE MELBOURNE OPERATING THEATRE."

To the Editors of THE LANCET.

SIRS,—As you have formed your opinion (THE LANCET, Aug. 10th, p. 275) from the bombastic remarks of "The Ghost" in *The Speculum*, I should like to give you my experience and opinion.

The building is one-storeyed, and is isolated from all the wards and offices of the hospital, but is connected to the main surgical wards by covered ways, and so it is much more likely to be kept aseptic than when the theatre is situated in the main building. I think I may safely say I have seen more operations performed in the Melbourne theatre than "The Ghost," but I have never yet seen a patient anæsthetised on the floor. It is true he is placed on a stand about eighteen inches high, which makes it a little, but not very, inconvenient to administer the anæsthetic. Though the Melbourne air generally contains more dust than that of London, in my opinion an examination of it would prove it to be much more aseptic than the soot and fog befouled atmosphere of this city; and if it is not so, it is the fault of the sanitary condition of the city, and not any fault in the construction of the theatre. As to light, I have seen London surgeons perform delicate operations in a November fog, in a light in which a Melbourne surgeon would refuse to perform a major amputation. If you had quoted his fantastic scheme for a new theatre, people would have known how to appreciate his remarks. I have calculated his model theatre would cover a space of 190 × 140 feet, without allowing for halls, passages, and store-rooms, and would comprise over seven rooms—a truly Utopian idea. As to the results of the hospital, considering the way the wards are overworked, they are very good. None but urgent cases can be taken in, and many cases are treated and operations done in the out-patient department which are never treated outside the wards here. The general cleanliness of the hospital surpasses anything to be seen in London. If "The Ghost" had turned his attention to the quarters of the resident medical staff and the want of accommodation in the wards, he would have had much better grounds for penning a philippic.

I am, Sirs, faithfully yours,

London, Aug. 19th, 1889. MELBOURNE STUDENT.

THE RECENT MEETING OF THE BRITISH MEDICAL ASSOCIATION.

WE have received from Messrs. Burroughs and Wellcome two excellent photographs, intended as souvenirs of the meeting at Leeds last week. One is a representation of the town hall; the other a view of the lake, Roundhay Park. We are asked to state that Messrs. Burroughs and Wellcome will, on request, have pleasure in sending a copy of the souvenirs to any member of the profession.

Merlin.—1. We think the form of certificate is responsible for the evil complained of by our correspondent.—2. We have no knowledge of the gentleman mentioned.

MEDICAL PRACTICE IN AMERICA.

To the Editors of THE LANCET.

SIRS,—Will any of your readers who have any experience give me information regarding the above? Also, is there scope for practice, and what capital would be required to gain a moderate practice, and the best part to go to?

I am, Sirs, yours obediently,

August 19th, 1889. J. R. P.

LA METTRIE, THE ARMY SURGEON.

AMONG the eminent army surgeons in whom France has been so prolific, there are few more interesting figures than La Mettrie. He studied medicine under Boerhaave at Leyden, and did splendid work at the battle of Fontenoy (May 11th, 1745). "Army surgeon La Mettrie," says Carlyle in his History of Frederick the Great, "of busy brain, expert with his tourniquets and scalpels, is thrice-busy in hospital this night. 'English and French all one to you; nay, if anything, the English better!' those are the Royal orders." Pity it was that the great anatomist and operator did not persevere in the work for which his genius best fitted him. But he was vain of his power with tongue and pen, and though, according to Carlyle, "wisdom of the highest nature was what he drove at," he did so "unluckily with open mouth, and mind all in tumult." He left the army soon after that busy Fontenoy evening, and entered on a crusade to put the whole world right. He attacked the Senatus of the Sorbonne in the wildest controversial way, and did not spare the medical faculty: "Doctor Astrue, Doctor This and That, of the first celebrity, taking it very ill," says Carlyle. So that La Mettrie had to get out of France rather in a hurry, "lest worse befell." He fled to Leyden, and from that safe distance continued his cannonade against the Sorbonne and the French physicians and surgeons; and then he turned his artillery against the Dutch, till Leyden became too hot for him. His "L'Homme Machine" (Man a Machine) is still read for its literary and logical brilliancy, and though, says Carlyle, "tumultuous La Mettrie meant nothing but open-mouthed wisdom by it, it gave scandal in abundance, so that even the Leyden magistrates were scandalised, and had to burn the afflicting little duodecimo by the common hangman." We next hear of La Mettrie at the Court of Frederick the Great, "seldom inexorable when there was worth recognisable," and from that conversation-loving monarch he received a pension which enabled him some time longer to keep up his controversial fire, "not of a malignant incendiary kind," says Carlyle, "but pleasantly lambent." He was first-favourite of Frederick till Nov. 21st, 1751, when he died, rather ignobly, if the jealous chroniclers of the Court are to be believed. According to one of these (Thiébault, whom Carlyle calls "unbelieveable"), La Mettrie was on terms so familiar with the king that he would enter Frederick's room as he would that of a friend, plump down whenever he liked, which was often, and lie upon the sofas; if it was warm, would take off his stock, unbutton his waistcoat, and fling his periwig on the floor. And yet the great monarch found qualities in him invisible to the Voltaires and Nicolais, his contemporaries, insomuch that he penned a handsome *éloge* on him, which was read some time after to the Berlin Academy.

Dr. T. Lucas Benham.—We should have pleasure in publishing a list of well-authenticated cases of cures of hydrophia if our correspondent would care to collect it.

THE FOOD OF THE CHILDREN OF THE POOR.

To the Editors of THE LANCET.

SIRS,—As I see a good deal of the results of the improper feeding of the infant children of the poor in the town in which I live, I intend to have some leaflets printed with short plain directions on the most important points to be given by the registrar to the mother when the birth is registered. If any of your readers have already done this, or would be kind enough to make any suggestions, I should be deeply obliged, as no doubt any hints would be useful.

I am, Sirs, yours faithfully,

Aug. 19th, 1889. PARISH DOCTOR AND M.O.H.

THE TONGA ISLANDERS.

THE British Vice-Consul at Nuknalofa, in the Tonga Islands, in his official report refers to the population of the islands, and remarks that although no census has been taken, it is believed that, like other South Sea aboriginal races when brought into contact with civilisation, with settled forms of government and missionary effort, the Tongans are decreasing in numbers. A severe epidemic of a bronchial character carried off a large number in the spring of last year. They are very subject to lung diseases, and a great number die of consumption. The custom of attending religious services before daylight and leaving warm blankets, either on a rainy morning or with a heavy dew on the grass, with the thermometer perhaps at 50 degrees, is not calculated to lessen the evil.

Therapeutist.—Some qualities of the drug are described in our present issue.

WRINKLES.

To the Editors of THE LANCET.

SIRS,—Will any of your readers inform me if they have any experience of the removal of wrinkles by electrolysis, as practised by Dr. Vernoy of Paris, and what is the *modus operandi* and strength of current employed?

I am, Sirs, yours obediently,

Clapham, Aug. 19th, 1889. NEMO, M.K. & Q.C.P.I.

Medical Diary for the ensuing Week.

Monday, August 26.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, daily at 10 A.M.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
ST. MARK'S HOSPITAL.—Operations, 2.30 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.

Tuesday, August 27.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same days, 2 P.M.

Wednesday, August 28.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M. Thursday & Saturday, same hour.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M.; Surgical Visits on Wednesday and Saturday at 9.15 A.M.

Thursday, August 29.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

Friday, August 30.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, August 31.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year	£1 12 6	Six Months	£0 16 3
TO CHINA AND INDIA	One Year		1 16 10
TO THE CONTINENT, COLONIES, AND UNITED STATES	Ditto		1 14 8

Post Office Orders and Cheques should be addressed to The Publisher, THE LANCET Office, 423, Strand, London, and crossed "London and Westminster Bank, St. James's-square."

ADVERTISING.

Books and Publications (seven lines and under)	£0 5 0

The Bradshawe Lecture

ON THE

DISTRIBUTION AND DURATION OF VISCERAL NEW GROWTHS.

Delivered at the Royal College of Physicians of London,

BY NORMAN MOORE, M.D., F.R.C.P.,

ASSISTANT PHYSICIAN AND LECTURER ON PATHOLOGICAL ANATOMY AT ST. BARTHOLOMEW'S HOSPITAL AND WARDEN OF ITS COLLEGE.

MR. PRESIDENT,—My first duty is to thank you for doing me the honour to appoint me to lecture on this occasion.

The subject which I have chosen is one on which nothing is to be learned in the medical treatises of ancient times. The Hippocratic writings show that the Greeks had observed that cancer sometimes affected internal organs, that it was a disease of adult life, and that in many cases the cancer continued to grow as long as the patient lived,[1] but they contain no rules for distinguishing this disease from similar conditions. The physicians of the middle ages were inclined to neglect observation, but they excelled in definition to such a degree that a reader who goes no further than the first paragraph of their statements on each disease will be inclined to think too well of their knowledge. Dr. John of Gaddesden was the most famous of English physicians before the foundation of this College, and his definition of cancer is: "Cancer est morbus maleficus, tumorem faciens cum duricie, vel ulcerationes faciens cum dolore et fetore et horribilitate."[2] But his further remarks show that in his time cancer was not exactly distinguished from other forms of tumour, of induration of tissues, and of ulceration. This defect continued for more than four centuries after the time of John of Gaddesden, though a vast collection of observations of new growths of all kinds was made by physicians throughout Europe in consequence of the active study of the morbid anatomy of the human body in its relations to clinical medicine, to normal anatomy, and to the anatomy of animals, which was in this country encouraged by your illustrious predecessor, Dr. Caius, and carried on by Harvey, Glisson, Lower, Willis, and many other Fellows of this College. The most famous of them in this part of medicine, Dr. Matthew Baillie, was a contemporary of more than one physician still living. His book, "The Morbid Anatomy of some of the most important parts of the Human Body," appeared in 1793, and received improvements from his hand till Oct. 1st, 1817, when he sent the fifth edition to the press. This admirable treatise, which is so full of precise and original accounts of what the author had himself seen that it can never become obsolete, contains many observations on new growths. It is easy for any pathologist to satisfy himself that Dr. Baillie was acquainted with the appearances of cancer of the œsophagus, stomach, and intestine, of the liver, of the pancreas, and of the bladder, with new growths of the thyroid gland, of the brain, of the lungs, of the ovary, of the peritoneum, and of the pericardium. He had made the observation that such new growths may infect the glands, for he says under the heading "Mesenteric Glands Cancerous" (p. 209): "When a portion of the intestinal canal becomes cancerous, some of the absorbent glands in the mesentery generally become affected with the same disease: this is in consequence of the matter of cancer being conveyed to these glands by absorbent vessels. The glands become enlarged in size, and are changed into hard masses, exhibiting a scirrhous or a cancerous structure." That the defect of definition of cancer from other conditions remained is, however, clear from what Dr. Baillie remarks on "large white tubercle of the liver (p. 231): "Hard white masses are sometimes found in the liver. They are often as large as a chestnut, but I have seen them both a good deal larger and smaller than this size. They are to be found near the surface of the liver in greater number than near the middle of its substance; two or three frequently lie contiguous to each other, with a considerable portion of the liver in a healthy state interposed between them and a cluster of similar tubercles. They consist of a firm opaque white substance, and are generally somewhat depressed or hollow upon their outer surface. The liver in this disease is frequently a good deal enlarged beyond its natural size.

The kind of tubercle which we have now described is much more rare than the other, and resembles more the ordinary appearance of scirrhus in other parts of the body. In one or two instances, however, I have observed a thick sort of pus lodged in this species of tubercle, resembling very much the pus from a scrofulous sore; and therefore I am rather disposed to think that this tubercle may be of a scrofulous nature, but no satisfactory opinion can be formed upon this single circumstance." These tubercles were what we should call masses of carcinoma or of sarcoma, and we can explain clearly how different are their nature and structure from those of scrofulous sores, to use Dr. Baillie's term. The first step towards the exact definition of the structure of cancer and other new growths was the observation of Leeuwenhoek, in 1674, that the epidermis consisted of minute scales placed side by side. In a letter to Oldenburg he says: "I mentioned that I could not otherwise perceive but that the scarf insensible skin consisted of small round scales, and declared my sense of the skin's fabric thus: that continually as it was worn away on the outside, it was supplied from beneath."[3]

I do not propose to take up your time with an account of the successive advances in our knowledge of the cellular structure of the skin and of other tissues of the body, and of the gradual abandonment of the word "epidermis" and growth of the use of Ruysch's word "epithelium," from Leeuwenhoek's description of the epidermis in 1674 to Waldeyer's enunciation in 1867 of the modern doctrine that carcinoma is a new growth originating in epithelium. But as it is on new growths originating in epithelium that most of my observations have been made, I will ask you at once to consider some well-ascertained facts in its structure and natural history.

An epithelium consists of a continuous surface of nucleated cells, sometimes flat and polyhedral, sometimes columnar in shape, and sometimes with intermediate forms, sometimes in one layer, and sometimes stratified. The cells appear under the microscope almost contiguous, and are held together by a very thin structureless interstitial cement substance. These cells are the descendants of those which at a very early period of life were formed first upon the outer surface of the animal as epiblast, and some of which afterwards as hypoblast came to line the inner surface of the animal. Their ancestors, the cells of the epiblast and of the hypoblast, having to cover a smaller area, were much fewer in number. They multiplied by division. This power their descendants in the adult epithelium inherit, and thus throughout life as some cells die, and are shed on the surface, fresh cells are formed and take their place. There is what may be called a regular rhythm of growth. If the epithelium is stratified, the cells of the lower layers divide and supply in regular order and interval of time the deficiencies of the superficial layer. If the epithelium is in one layer, similar lateral changes take place in regular rhythm. The cells of the epiblast and of the hypoblast have another peculiarity. Their series can dip down into the subjacent structures and there continue their growth. The epiblast by this kind of ingrowth forms the stomodeum, which in time becomes the cavity of the mouth, and the proctodeum, which becomes the rectum. The hypoblast has numerous ingrowths which become glands. These ingrowths are numerous and normal in both epiblast and hypoblast. Now and then they occur at irregular points, as when the epiblast dips in and becomes separated from its original surface and forms one of those dermoid cysts containing teeth and hair which so long confused the ideas of anatomists as to the development of the ovum. This power of ingrowth is not displayed normally after its adult condition is reached. Its cells then proceed to succeed one another in a definite rhythm and along a definite line. The powerful effect of heredity is illustrated by the regularity of their plane and direction of growth. Is it never interrupted? May we not regard a carcinoma as a simple interruption of this regular rhythm of growth? What the disturbing influence is we do not know. Probably it is

[1] Προρρητικον, ii., 11. [2] Rosa Anglica, Venice, 1516, p. 125-6. [3] Phil. Trans., 1692-3.

Digitized by Google

not always the same. It seems certain that as regularity of growth is a hereditary quality of epithelial cells, so irregularity may also be inherited by some epithelial cells. Thus the cells of every primary carcinoma are normal epithelial cells growing inward instead of following their normal plane of growth. The stroma in which they are set cannot be considered as the representative of the very thin interstitial cement substance. It is in parts formed by subjacent tissue, carried in with the epithelium, just as the mesoblast in many normal curves follows the epiblast. In other parts it is formed by fresh connective tissue, the formation of which is due to the irritation set up by the epithelial ingrowth. The same method of explanation may be applied to many sarcomata, new growths originating in any of the tissues developed from the mesoblast. Such is the primary new growth. Others appear in distant parts of the body. Are they contemporaneous morbid alterations of the rhythm of cell growth, or are they the immediate descendants of the primary growth? As to settle this point is essential to the study of the distribution of new growths of the viscera, I shall shortly describe three cases which demonstrate what most pathologists would now admit—that the later growths are the descendants of the first growth.

A man aged thirty-seven, by occupation a chimney-sweep, was admitted into St. Bartholomew's Hospital under my care on Sept. 8th, 1883. He had had hæmoptysis for a month before admission, and thought that he had become short of breath in April, 1883. He had a pain in his chest which kept him awake at night. The cardiac impulse could not be felt, but the heart sounds were audible and normal. The breathing sounds were normal. On Sept. 24th a small swelling was observed to have appeared on his left clavicle. On Oct. 3rd his breathing was shorter, and the following were the physical signs in his chest: absolute dulness on the left back from the spine of the scapula downwards; just over the root of the left lung, and there only, bronchial breathing; in front a peculiar hyper-resonant note just below the left clavicle; elsewhere on the left side absolute dulness; right side normal. Three days later I had paracentesis performed, and twenty-seven ounces of clear serum were drawn off. The dyspnœa was but little relieved, and three days later the man died. The day afterwards I examined his body. The pericardium contained blood-stained fluid, and both its surfaces were infiltrated with a dense whitish new growth. At the root of the left lung the growth had invaded the main bronchus. The bronchial glands were infiltrated. There was a small nodule on the sixth left rib. Below the diaphragm the growth was only present in the supra-renal bodies. I examined the new growth microscopically in every part in which it occurred, and in all situations it had the same characters. It everywhere consisted of large oval or polyhedral nucleated cells contained in well-marked alveoli. Precisely such cells cover the surface of the pericardium. Obscurity of cardiac sounds was the first physical sign observed. It was followed by pleural effusion, due to the pressure of the growth as it extended from the pericardium into the lung. The growth on the clavicle was observed to begin to grow some time after the physical signs indicated a growth in the pericardium. Its structure was precisely the same as that of the pericardial growth. No such cells occur in the substance of the supra-renal body, yet the nodule of new growth there had precisely the same cellular appearance as that on the pericardium. I believe the growth to have been primary in the pericardium (1) because the physical signs indicated that new growth began there, (2) because the largest and densest mass of new growth was found involving the pericardium, and (3) because the form and arrangement of the cells of the new growth were identical with those of the normal endothelial cells of the pericardium. As to the growths on the clavicle in the lung and in the supra-renal body, their structure was the same as that of the pericardial growth. In the substance of the lung and in the supra-renal body and clavicle no cellular structure exists normally which is like the structure of the endothelium of the pericardium. The conclusion is obvious that these large polygonal cells grouped together in alveoli in the lung and in the supra-renal body are the descendants of the similar cells of the endothelium of the pericardium. The new growth, due in the pericardium to an alteration of the normal rhythm of growth of the pericardial cells, is in the supra-renal body and lung due to the transference from the pericardium of some of these cells. The pericardium is the mother country of these cells—the masses in the lungs and supra-renal bodies are colonies. I have heard, Sir, that in the midst of your professional labours you have been so wise as to give some of your time to philosophical studies, and I may therefore venture to remind you of a famous passage in which one of the greatest writers and philosophers which this country has produced points out how colonists when they emigrate carry with them to their new abode the part of the character of their original nation predominant at the time of their emigration. Some of the cells of the endocardium which is the seat of morbid growth are carried off by the circulation or in the lymph channels, and form colonies in a region of totally different structure, the supra-renal body, and there illustrate the principle laid down by Burke. They carry with them the power of developing fresh cells of the original form and the tendency prevalent when they left the pericardium for these cells to multiply in irregular groups, instead of in a single layer on an extended surface.

The second example, illustrating the relation of descent between a primary new growth and secondary new growths is afforded by a man aged forty-seven, who was first under my care as an out-patient, and afterwards in St. Bartholomew's Hospital, to which he was admitted on Aug. 25th, 1888. He died on Sept. 22nd in the same year. Three years and five months before his admission his right eye had been removed by operation for a new growth in it, which proved on examination to be a melanotic sarcoma, growing from the choroid membrane, and containing dark pigmented connective-tissue cells of the kind normally abundant in the capillary part of that membrane. In August, 1888, when I saw him first, he had a greatly enlarged liver. The socket of his right eye was empty and showed no sign of disease. His left eye was natural. After death the enlargement of his liver was proved to be due to its infiltration by numerous masses of new growth mainly consisting of dark pigmented connective-tissue cells, precisely resembling those of the capillary part of the choroid membrane, and wholly unlike any normal cellular structure of the liver. Some of the abdominal lymphatics and the kidneys contained similar masses of pigmented sarcoma. Neither kidneys nor lymphatics normally contain any such pigmented connective tissue. The conclusion is surely obvious that the abnormally growing but normally constructed pigmented connective-tissue cells of these masses in the liver, abdominal lymphatics, and kidneys were the descendants of the original new growth starting in the normal pigmented cells of the choroid. Their colonising ancestors had already left the original mass in 1885. The growth in such a case is sometimes said to recur in such and such a part after an operation for its removal, but the phrase is incorrect. It does not recur. It began in the choroid, and thence started pigmented cells, which were already on their way to other regions when the original growth was extirpated in the eye. It was truly extirpated, for no morbid change except atrophy of the root of the right optic nerve was discoverable in the head. If I may again borrow an illustration from history, I would compare the melanotic growth in the liver—surviving and flourishing long after the destruction of the original seat of its cells in the choroid—to the Parsi community of Bombay, which preserves in a colony the race and beliefs of a Persian empire destroyed centuries ago by the Mussulman armies.

A third example of the relation of the secondary nodules of a new growth to the primary new growth is that of a man aged fifty-two, who was a patient of Dr. Gee in St. Bartholomew's Hospital, and whom I had the opportunity of observing in the wards and in the post-mortem room. He died of carcinoma of the uppermost part of the rectum growing from the epithelium lining the small crypt-like glands of the mucous membrane. The epithelial cells of these glands are columnar, and they arrange themselves in conformity with the shape of the glands in circular or ovoid tubules. The primary growth had infiltrated the submucous tissue, and consisted entirely of perfectly and imperfectly developed columnar epithelium, arranged exactly as is the normal epithelium of the tubular glands of this part of the rectum. Before death several nodules had grown so as to be felt on the surface of the liver through the abdominal wall. After death many such were found in both lobes of the liver. These masses in microscopic sections showed the columnar cells and tubular arrangements which I have already described as found in the new growth in the rectum. Just as the cells like those of the pericardial endothelium found forming a mass in the supra-renal body, and as the pigmented cells of the choroid kind

Digitized by Google

found in masses in the liver, are, from their resemblance to those of their original seat and dissimilarity to any cells of the organ in which they were found, believed to be secondary and descended growths, so these columnar epithelial cells arranged in tubules occurring in the liver are to be regarded as secondary to and descended from the primary abnormal growth of the normal columnar epithelium of the tubular glands of the rectum.

It would be easy to multiply examples. I have chosen these three because in each case the clinical history pointed to the new growth having begun in a particular region, and because the microscopic character of the cells of the region of origin were well marked, peculiar, and unmistakable. I wish these examples to illustrate the law that malignant new growths have a primary seat in which the abnormal growth of normal epithelial cells begins, and that the cells of all secondary growths are descended from these. The microscopic characters alone are, however, not always, as they were in these three cases, sufficient, when studied with the clinical history, to establish after death the position of the primary growth. When these, taken together, leave the determination of the primary growth uncertain, it may be usually settled by a consideration of the naked-eye characteristics of the several parts of the growth. If the growth has been comparatively slow, then the densest mass is probably the oldest. If the growth has been rapid, then the oldest mass will probably be that which is softest, in which most degeneration has taken place. It is essential, in the investigation of this point, always to consider together these three circumstances — microscopic structure, naked-eye appearance, and clinical history. The growth into the substance of an organ of a carcinoma or sarcoma always gives rise to the formation of fresh connective tissue. When the growth is slow, much connective-tissue formation is present and the growth is dense. When the growth is rapid, but little connective tissue is formed. Bearing this in mind, the enlargement of lymphatics near the growth must not be taken as a proof that the new growth itself has begun in them; their enlargement is frequently due to simple inflammation. In the same way, it is important, by examining numerous microscopic sections, to guard against the error of mistaking the round cells of the inflammatory process, which are often very abundant round the growth, for the cellular structure of the growth itself. The extensive degeneration which often takes place in the epithelial cells of a new growth on the surface of a mucous membrane adds to the difficulty of determining the nature of the cellular structure of the new growth unless many sections are examined. In the new growths which I am about to mention I have endeavoured to avoid error due to these circumstances. In each case I have examined the body myself, and have observed both the distribution and the naked-eye appearances of the fresh new growth, and have afterwards examined several sections of the primary growth and of the several secondary growths. In nearly every case I have examined microscopically the secondary growth in all places of its occurrence, and I have always done so when the naked-eye appearances left any room for doubt as to whether what seemed a mass of new growth was really so. In a few instances where many organs were the seat of secondary deposit, and where nearly all were successfully examined, accident prevented the examination of some one secondary nodule. With this altogether unimportant exception, the statements as to the nature of the new growths which I shall mention are all based on full microscopical examination. Although for practical purposes we may often be quite sure of the nature, say, of a carcinoma of the œsophagus, still it seems desirable, in establishing sound premisses from which to deduce conclusions as to the distribution and duration of new growths, to deal with only those cases in which the precise nature of the growth has been determined by microscopic examination. My own contribution is a very small one; but if similar collections of observations are made, there will be in time a sufficient accumulation for certainty in these important points with regard to visceral new growths: the directions in which they tend to grow, and to what organs in each case they tend to distribute secondary growths from the primary mass, and the duration of this growth—a period of extreme interest, since, so far as the possibilities of our art are at present, we must admit that it is conterminous with the survival of the patient.

Following the strict method I have described, I have to lay before you the results of the examination of one hundred and twenty-three cases of new growths in the internal organs of the body. Most of my remarks have relation to new growths from epithelium, for of these cases one hundred and two were carcinomata and twenty-one sarcomata, among which I include growths from endothelium, though some of their characters are so distinct that it is well to keep for them the distinctive term "endotheliomata." As to terms, I may add that the term "scirrhus," which in Heberden and all earlier writers was applied to all growing indurations of tissue in soft parts, whether due to new growth or to the process we term "cirrhosis in the liver" and "sclerosis in the brain," has little value as a pathological term for a new growth. Hardness is a common character of widely different new growths, and some carcinomata are softer than some sarcomata. If the term "scirrhus" is still to continue, it ought to be used as a purely clinical expression for any dense and therefore slow-growing new growth. The terms "medullary" and "encephaloid" are open to the same objection, and as they are not useful in clinical observation it would be well if they could be allowed to drop out of use altogether. All three terms date from a time when the origin of new growths was unknown, and refer to points in their description which are not distinctive of their nature. Every new growth should now be described by mentioning the form of its cells and their arrangement in relation to one another or to any intervening tissue. The term "epithelioma" may also with advantage fall into disuse, since it has practically become a synonym for carcinoma. A new growth may become adherent to neighbouring structures and grow into them, and this may be termed "growth in continuity"; or it may give origin to the formation of masses in distant organs, when these are termed "secondary growths." It is of considerable importance to observe this distinction, and I shall do so in the account of visceral new growths to which I shall now proceed, beginning with the alimentary canal and its large glands—the liver and the pancreas, and going on to the lungs, heart, and pericardium, spleen and lymphatics, kidney and brain.

The *œsophagus* is a common seat of new growth in men, a very rare one in women. In fifteen cases which I examined I found that the new growth was in all a carcinoma. All had a well-marked stroma. In five the cells contained in the meshes of the stroma were some of them columnar, suggesting that the morbid epithelium in this case was that of the small mucous glands. In the other ten the cells were polyhedral, or rounded, and of flat appearance, and the morbid epithelium was clearly that which forms the general lining of the œsophagus. In none were there any cell nests, such as are common in cancer of the lip. In four cases the new growth extended from the lower end of the œsophagus into the stomach. In six there was a growth in continuity into one lung. The commonest seat of secondary growth was the liver, in which masses were found in seven out of fifteen cases. Secondary growths occurred in the lungs in five cases and in the heart in five. In four, growths were found in the kidneys; and in three of those in which there was growth in the heart there was also growth in the kidneys. The pancreas, spleen, and supra-renal body were were each affected in one case. The following conclusions are justified: (1) That in carcinoma of the œsophagus the new growth is rarely confined to the œsophagus; (2) that it may grow along the œsophagus into the stomach; (3) that it may grow directly into the lung, and that this is a frequent occurrence; (4) that it may grow directly into the mediastinal glands; (5) that it may, though rarely, infiltrate the dorsal vertebræ; and (6) that it is frequently associated with widespread secondary growths, of which the commonest seat is the liver, and that, after the liver, the lungs, heart, and kidneys are more often affected than any other viscera. It is worth while to point out, in addition, that the tendency of the new growth to cause adhesion of the œsophagus to the lung sometimes leads to perforation of the œsophagus, the passage of food into the lung, and the patient's death from gangrene of the lung, or from pneumonia, before actual infiltration of the lung by the new growth has taken place.

The *stomach* is a common seat of new growth in both sexes. In twenty-nine cases, eight in women and seventeen in men, which I examined microscopically, I found the new growth in all to be a carcinoma. Its stroma was always abundant. The cells in twenty-one of these cases were columnar and spheroidal, with intermediate forms, and probably originated in the layer of columnar cells which line the whole stomach, the pyloric glands, and the peptic

Digitized by Google

glands. In four cases the cells were polyhedral, resembling and probably growing from those which normally occur at the neck of the pyloric and of the peptic glands. Very great degeneration of many of the cells of the new growth was often present, and in a few cases there was copious hæmorrhage into its substance. In twenty-three out of the twenty-nine examples the new growth was densest at the pylorus, and had grown thence in the gastric wall towards the œsophagus, in eleven cases infiltrating the whole gastric wall. In three cases it was most dense, and radiated from what seemed to have been a simple gastric ulcer of long standing. In two the seat of new growth was the cardiac end, and in one the posterior wall only. In one case the growth, densest at the pylorus, had filled the whole gastric wall and extended a little way into the œsophagus. In one case a mass of new growth projected through the pyloric orifice, but in no case was the wall of the duodenum in the slightest degree affected. Growth from the stomach in continuity into the lymphatics along its edge occurred in seven cases, into the liver in four, into the diaphragm, omentum and mesentery, pancreas and transverse colon in two each, and into the œsophagus, ascending colon, spleen, vertebral column, and vena cava inferior in one each. Secondary growths occurred in the liver in fourteen, in remote lymphatics such as the lumbar glands in nine, in the pancreas in six, in the lungs in five, in the peritoneum generally in three, in the kidney in two, in the heart, spleen, and supra-renal in one each. In three cases only the growth did not extend anywhere beyond the stomach. The following conclusions are justified: (1) That carcinoma of the stomach generally grows from the pylorus towards the cardiac end of the cavity; (2) that the growth is rarely continued into the œsophagus, but more often than into the duodenum; (3) that in about one-fourth of the cases the growth extends directly into the lymphatics along one or both curvatures of the stomach, forming dense masses which may often be felt through the abdominal wall; (2) that after these lymphatics its most frequent seat of growth in continuity is the liver; (5) that it may also grow in continuity, though with less frequency than into the liver, into the diaphragm, omentum and mesentery, pancreas and transverse colon, and less often still into the ascending colon, spleen, vertebral column, and vena cava inferior; (6) that in two-thirds of the cases there are secondary growths, and that in one-third these are widespread, affecting one or more regions; (7) that the commonest seat of secondary growth is the liver, and next to it remote lymphatics, especially the glands in the hilum of the liver, the lumbar and mesenteric glands, and those of the mediastinum; (8) that after these the pancreas and lungs are most often the seat of secondary growth, and with nearly equal frequency; and (9) that secondary growths are rare, but may also occur (in the order of frequency) in the peritoneum generally and in the kidney, and least often, and with equal rarity, in the heart, spleen, and supra-renal bodies.

I have examined nine growths in the *colon*, of which four were in the ascending colon, two in the transverse, and three in the descending. As these are purely artificial divisions, I shall treat of the growths as one series. Three were in women, six in men. All were carcinomata. In eight the cells were distinctly columnar. In one, in which the stroma was very dense, I found no well-formed columnar cells, but only spheroidal cells. All had no doubt originated in the columnar-celled epithelium which lines the large intestine and its mucous glands. Two had grown in continuity into the duodenum, two into the abdominal wall, one into the ileum, one into the stomach, and one into the liver. In two, small lymphatics near the intestine contained new growth, but there was no general infiltration of the abdominal lymphatics. The only remote seat of secondary growth was the liver, and that in only one case. The conclusions justified are: (1) That carcinoma of the colon tends to spread by direct continuity, and may thus, according to its situation, penetrate the stomach, duodenum, ileum, or abdominal wall; and (2) that it rarely has secondary growths, and that when these occur they are commonest in neighbouring lymphatics, and may rarely be found in the liver.

New growths of the lower part of the *rectum* are commonly sent into the surgical wards of a hospital, and it thus happens that nearly all the cases I have examined are of the upper part. They are eight in number, three in women and five in men. All were examples of carcinoma; in six the cells were columnar, in two polyhedral, and in one I could find only spheroidal cells. The commonest origin of the cell growth was probably the epithelioma of the mucous glands. In the two cases with polyhedral cells the new growth was nearer the termination of the intestine, one just within the anus, the other a little higher. The one which most certainly belonged to the area of the proctodeum had as widely spread secondary growths as any, and had them abundantly in the lumbar glands, liver, and pancreas. The other with polyhedral cells had neither growth in continuity nor secondary deposit. The remainder had no growth in continuity, unless in one case in which the peritoneum was adherent over a very small area, and here I found none, though I suspected it. Five were without any external growth. In those which had secondary growths the lumbar glands were infiltrated in two, the liver in three, and the pancreas in one, in which both liver and lumbar glands were affected. Even on so small a series it is fair to point out: (1) That in carcinoma of the rectum a majority of the cases have neither growth in continuity nor secondary growths; (2) that the lumbar glands and the liver are the most frequent regions of secondary growth; and (3) that the pancreas is sometimes infiltrated. On reviewing the new growths of the alimentary canal, it is worth note: (1) That the stomach is a more frequent seat of new growth than the œsophagus, and the œsophagus than the colon, and that notwithstanding its greater length, and therefore greater area of epithelium, the small intestine is the least frequent of all; (2) that new growths of the œsophagus lead to the most widespread secondary growths, and new growths of the colon to the least widespread; and (3) that new growths of the colon have the greatest tendency, perhaps owing to their situation, to grow directly into the other parts of the alimentary canal.

The *gall-bladder* and *large bile-ducts* are a seat of new growth in both sexes, and I have examined ten cases, five in each sex. All were examples of carcinoma. Polygonal and columnar cells, with intermediate spheroidal and subspheroidal forms, were present in all cases, corresponding exactly to the epithelial cells lining the ducts and the gall-bladder. In one case the common duct only was affected. In all the others the duct near the gall-bladder, and the upper part or the whole of the gall-bladder, were the seat of growth. Gall-stones were present in only four of the cases, and in a fifth a dead, partly calcified hydatid cyst occupied the fundus of the gall-bladder. In six of the cases the growth extended in continuity into the liver substance for a very short distance. In two it grew directly into the wall of the duodenum, and in one of these into the lumbar glands as well. Of secondary growths, the lymphatics were the most frequent seat, especially the glands in the hilum of the liver, the lumbar and the mesenteric glands. In only two cases was there wide general infiltration of the abdominal lymphatics. In three cases there were secondary growths in the lungs; in one only a separate secondary growth in the liver. In one a scattered growth in the peritoneum. In two cases there was no growth anywhere else. The following conclusions may be stated: (1) That carcinoma of the gall-bladder and large bile-ducts (generally the common duct) usually grows directly into the liver; (2) that secondary deposits, if present, are not widespread; (3) that their most frequent seat is the abdominal lymphatics, but that they may occur, in order of frequency, in the lungs, the liver, and the peritoneum.

The *liver* is a rare seat of primary new growth. I have examined three, two of them in men. All three were examples of carcinoma. Two had large polyhedral cells, which were jaundiced (though there was no general jaundice), and the third had polyhedral and columnar cells. Those with only polyhedral cells may have begun in the ultimate termination of the bile-ducts or in the liver-cells, the one with some columnar cells a little lower down in the bile-ducts. In one case the growth had extended in continuity into the omentum. There were no secondary growths except in the nearest lymphatics, and in a lymphatic on the external surface of the pericardium.

Primary new growth in the *pancreas* occurs in both sexes. Of eleven cases which I have examined, six were in men, five in women. All were examples of carcinoma, with spheroidal and columnar cells closely resembling those of the gland. Growth in continuity into the stomach, gall-bladder, and transverse colon was present in one case, and into the duodenum in another, and in a third into the lymphatics in the hilum of the liver. There were secondary

Digitized by Google

growths in seven cases; in the most widespread example in five separate localities. Next to the neighbouring lymphatics the liver was the most frequent seat, and was infiltrated in six cases, the lungs and the kidney in two, and the peritoneum and heart in one each. The conclusions are: (1) That in carcinoma of the pancreas growth in continuity is rare, but may take place into the stomach, gall-bladder, transverse colon, or duodenum; (2) that secondary growths are not usually widespread, and that their commonest seat is the liver; and (3) that they may also occur in the lungs, kidney, peritoneum, and heart. It is worth mention that jaundice was present in all the cases but one.

Primary new growth in the *lungs* may be a carcinoma or a sarcoma. I have examined eleven, ten of them in men. In all, the new growth formed a dense whitish mass, thickest about the root of the lung. In three the growth was a sarcoma, consisting of densely packed round cells, without any stroma, and probably growing from the lymphatic glands at the root of the lung. The other eight were carcinomata, with dense stroma, and columnar or spheroidal cells. In these the new growth probably originated in the epithelium of the mucous glands of the bronchi. In the three sarcomata there was growth in continuity into the bronchial glands, and in one case into the right auricle. The secondary growths were into the liver and pancreas in two cases, into the brain and supra-renal in one each, and in one into the vertebral column. The distribution of the carcinomata was similar. One grew in continuity into the right auricle; one had penetrated several ribs; one had secondary growths in the brain. There were secondary growths in the pancreas in half the cases; into remote lymphatics in three; into the liver in two; into the supra-renal, kidney, and spleen in one each. In one case only the growth was confined to one lung, and the bronchial glands were not infiltrated. One of the cases illustrated the necessity for minute examination of all details in the investigation of new growths. The patient had sudden right hemiplegia shortly before and up to her death. It seemed probable that a secondary growth had appeared in the brain, as sometimes happens both in carcinoma and in sarcoma of the lung. At the post-mortem examination I found an embolus plugging the left middle cerebral artery, and microscopic sections of this embolus showed it to consist of blood-clot only. The fact that a secondary growth may occur in the brain, in new growth in the lung, deserves notice, and the possibility of direct growth into the heart is also remarkable.

All the primary new growths of the *heart* and *pericardium* (only five in number) which I have examined proved to be endotheliomata, consisting of large polyhedral cells, arranged in well-marked stroma, and so exactly resembling the cells which line the pericardium that there could be no doubt that they were the origin of the growth. Both surfaces of the pericardium were infiltrated. In one of the cases the growth extended to the endocardium. In three there was a continuous growth into one or both lungs. In all but one case secondary growths were widespread. In all, the mediastinal lymphatics were infiltrated, and in two the lumbar glands. In three there were secondary nodules in the lungs; in two there were nodules in the liver, in two in the spleen, in two in the pancreas, in two in both kidneys, and in two in both supra-renals. In two cases there was a secondary growth on a clavicle. It is perhaps not safe to adopt more than two conclusions: (1) That endothelioma of the pericardium may grow directly into the lung; and (2) that its secondary deposits are usually widespread, and may include the liver, pancreas, spleen, kidney, and supra-renal body.

I have seen but one case of new growth primary in the *spleen*. It was a sarcoma of mixed cells, round and elongated without any stroma, and it grew directly into the stomach, diaphragm, and abdominal lymphatics, without any secondary growths.

Two cases of sarcoma primary in the *lymphatics* may be mentioned here. The new growth consisted of small round cells grouped in the meshes of a connective tissue, and was of the variety known as a lympho-sarcoma. It grew in continuity into the outer part of the pericardium in one case and into the right lung in the other. There were no remote growths, except a small nodule in the right lung in the example in which the pericardium was infiltrated.

I have only examined four cases of primary new growth in the *kidney*. Three in adults—two men and one woman—were carcinomata, consisting of spheroidal cells arranged in a well-marked stroma, and in one case in circular alveoli like tubules. One was a sarcoma growing from the pelvis of the kidney in a child aged two years and a half; in this case there were no secondary growths. In all the cases one kidney only was affected. The only growth in continuity was in one carcinoma, and was into the right supra-renal body. In two of the carcinomata there were growths into both lungs and into the liver, and in these cases the lumbar glands were also infiltrated. In the third carcinoma, that with the tubular arrangement of cells, the growth was confined to the left kidney. In two of the cases a ragged calculus occupied the pelvis of the kidney. It deserves note that while in new growth of the heart, whether primary endothelioma or secondary carcinoma, the kidney is sometimes affected; in none of these four cases of new growth in the kidney was the heart affected.

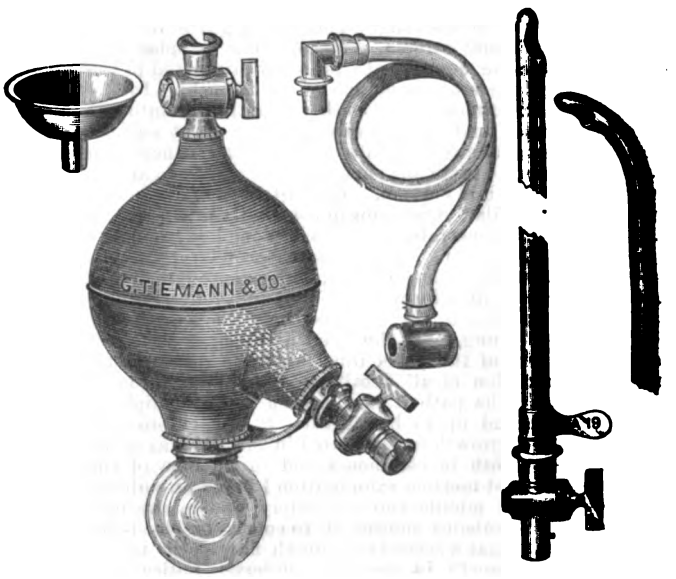
I have examined six cases of primary growth in the *brain*. All were growths of the genus "sarcoma." Three were in the cerebellum, one in the pons Varolii, one in the left cerebral hemisphere, and one in the optic chiasma. In only one was there any secondary growth except in the brain itself, where in two cases there were several. The extra-cerebral secondary growth in this one case was in the right supra-renal body.

I have now mentioned one hundred and fourteen examples of various new growths. In none of these were there any secondary growths in the uterus, ovaries, or testes. I have not accumulated sufficient observations on new growths of the generative system to enter upon that part of the subject. It is, moreover, one in which the difficulty of determining precisely the primary growth and its nature is often very great, owing to the rapid and extensive degeneration which often takes place. I have also omitted, as requiring larger discussion than this lecture permits, cases of widely spread and rapidly growing sarcoma in children, sometimes involving the skeleton, and sometimes almost all tissues but the bones. It remains to consider the duration of the new growths I have described. In each case I have taken from my own note-book when I had seen the patient during life, and from the careful records written from day to day by the house physicians at St. Bartholomew's Hospital, when I had not, the date of the first unequivocal symptom of new growth—as, for example, in cancer of the œsophagus, dysphagia; in cancer of the pancreas, jaundice. This clearly does not indicate the beginning of the disease, but it does mark the commencement of its distinct symptoms, and generally the time at which a physician is first likely to see it. In some of the cases I was unable to determine the duration. I shall mention the longest duration I could make out, and the shortest duration, and the duration of the majority of cases.

In carcinoma of the *œsophagus*, the majority of cases terminated within eight months, the longest case lasted thirteen months, and the shortest two months. In carcinoma of the *stomach* the majority of cases (in both sexes) lasted more than nine months, and half the cases from nine to eighteen months. The evidence seemed conclusive that one case (the longest) lasted sixty months and another thirty-six months; but these were the only ones which exceeded eighteen months. The shortest case lasted four months, and nearly a quarter of the cases lasted less than six months. In carcinoma of the *colon* the majority of cases lasted from ten months to nineteen months, which was the longest duration, and the shortest duration was four months. In cancer of the *rectum* the majority of cases lasted from four months to six months. The longest duration was thirteen months, the shortest three months. The duration of the three cases of cancer of the *liver* was respectively ten, seven, and five months. In cancer of the *pancreas* the majority of cases lasted from five to seven months; the longest lasted twelve months, and the shortest five weeks. In carcinoma of the *lung* a majority of cases lasted from seven to nine months, which was the longest duration; the shortest duration was three months. In the three cases of sarcoma of the lung the duration was respectively twelve months, ten months, and five months. In endothelioma of the *heart* and *pericardium* I could not satisfactorily determine the duration in most of the cases. In two which I observed throughout it was about six months. In the single case of sarcoma of the *spleen* the patient was under my own observation, and his illness lasted seven months. The two cases of lympho-sarcomata of the *lymphatics* each lasted two months. In carcinoma of the *kidney* the longest duration was nine months, the shortest six months. In the

Digitized by Google

sarcomata of the *brain* the duration of the majority of cases was from one to three months—the longest duration; and the shortest duration was four weeks. The large majority of cases of new growth in the viscera thus seem to terminate within a year from the appearance of distinct symptoms. In some cases, a period of doubtful health preceded the onset of undoubted illness, but this period I found so difficult to define that, as a safer assistance in determining the true duration of growth, I have drawn up a table of nine cases of what may be called external new growth (removed wholly or partially by operation). These show longer periods of time. Seven of them were cancers of the breast. A majority of the patients lived for from twenty-four to fifty-one months, and the shortest duration recorded was fifteen months. A man whose eye had been removed for melanotic sarcoma lived for forty-two months. The secondary growths in all the cases of carcinoma were widely distributed. Out of seven, the liver was infiltrated in five, the lung in four, the kidney in three, the spleen in two, and the heart, thyroid, and brain in one each. If it be supposed that after the operation only a very few morbid epithelial cells remained in the body, we have here a measure of how long they take to grow to a wide distribution—a period ranging from fifteen to fifty-one months. The intermediate durations are sufficiently near to make the mean a useful quantity. It is very nearly twenty-six months; or, omitting the single case of fifty-one months, somewhat more than twenty-one months. If this period be added to that determined by the symptoms, it seems likely that it may give an approximation to the true duration of the disease. For practical purposes, however, the determination of the observable period is far more important, and in every inquiry which we make as physicians practical usefulness to sick men ought to be our chief aim.



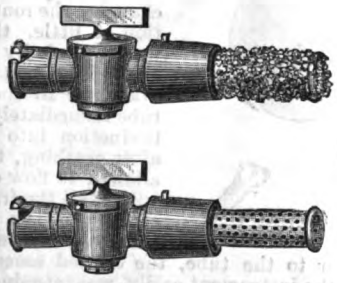
I hope that the observations recorded in this lecture, and the conclusions based upon them, are likely to be of use in diagnosis, as aiding in determining the probable situation and nature of internal new growths; in therapeutics, since treatment can only be safely based on an accurate diagnosis; and most, perhaps, in prognosis. In the Hippocratic writings, prognosis not only means the prediction of the event, but the prevision of the course of a disease and of all the probable incidents and opportunities of treatment likely to occur. I have tried to make this lecture a contribution to prognosis in this wider sense. The prognosis of our day is better than that of the Greeks, for it includes among its premisses the sure observations of morbid anatomy, and if Hippocrates could survey the practice of medicine as it now exists, I do not doubt that he would adhere to the opinion he expressed so many ages ago—that the most important thing for a physician is that he should practise forethought, and always have before his mind what has happened, what is happening, and what will happen in the case which he is treating. *Τὸν ἰητρὸν δοκέει μοι ἄριστον εἶναι πρόνοιαν ἐπιτηδεύειν.*

THE "PERFECTED" EVACUATOR.

BY FESSENDEN N. OTIS, M.D.,
CLINICAL PROFESSOR OF GENITO-URINARY DISEASES IN THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK, ETC.

THE credit of conceiving and carrying to ultimate success the operation of removing stone from the bladder by lithotrity at a single sitting is indisputably due to Professor Henry J. Bigelow of Boston. The method of crushing the stone has not materially changed from that pursued in former times, although we are indebted also to Professor Bigelow for more powerful lithotrites. These at once became a necessity when attacking the large and hard stones, which the field of his brilliant operation quickly embraced. With the heavier instruments now available it is rare indeed to find a stone which in skilled hands is beyond their compass. After the ability to use large evacuating tubes (from 25 mm. to 30 mm. in circumference, and even larger) was demonstrated, the evacuation of the débris seemed easy of accomplishment. The first instrument, a modification of Clover's, devised by Professor Bigelow, answered the purpose admirably in the main, but was soon found to permit a return to the bladder of a portion of the débris after it had been deposited in the receiver—a fault which did not prevent the accomplishment of many notable successes by this method; but Professor Bigelow at once began a series of elaborate and expensive experiments to remove the difficulty. Sir Henry Thompson of London, who soon adopted Professor Bigelow's operation, and contrived instruments of his own for its accomplishment, found the same difficulty to contend with. A sharp rivalry between these distinguished surgeons—to construct an evacuator which should act by the most direct and shortest route, and yet perfectly prevent the return of débris to the bladder—began in 1879, and for the several succeeding years furnished to the journals (chiefly the London LANCET) many interesting illustrations and much animated discussion. After various modifications and expedients had been adopted and discarded during a period of several years, Professor Bigelow, in 1883, presented the instrument, which has remained from that time up to the present (1889) without modification. In presenting his improved instrument to the profession in THE LANCET of Jan. 6th, 1883, Professor Bigelow says: "However otherwise arranged, a satisfactory aspirator should have some device near the catheter to act as a trap for débris, and secure every fragment that has passed it. The chief difference among evacuators now is in the certainty with which they retain the fragments they have aspirated. Any instrument will draw out the fragments, but few hold them securely, for the débris does not always fall into the glass receiver, nor does it always remain in it; on the contrary, it is easily carried back into the bladder. This defect in the action of the evacuator has received little attention from surgeons, although it is the only point connected with the instrument which offers any difficulty whatever. Until recently it has been remedied only by sacrificing simplicity in the apparatus."

FIG. 1.



Professor Bigelow's latest evacuator (1883). Holds 10½ oz. Weighs 24 oz. (troy) empty, 34½ oz. filled.

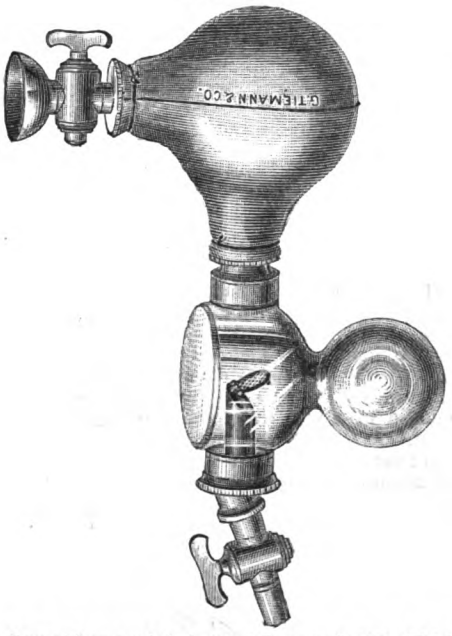
In the latest instrument of Professor Bigelow (Fig. 1) the route to the bladder has been changed to correspond with that of Sir Henry Thompson, in which the evacuating tube was attached directly to the evacuator, without the intervention of tubing, as in Professor Bigelow's previous instruments, thus apparently giving both surgeons the advantage of the same and the shortest route to the bladder. In place of various contrivances, ball, valves, traps, and strainer of previous modifications, a perforated tube was inserted into the lower side of the rubber bulb, and continuous with a stopcock connected directly with the evacuating catheter. This perforated tube or strainer was claimed to

Digitized by Google

prevent effectually the return of débris into the bladder; and, in operation, it was proved to do so; but the strainer, while working perfectly in experiments with crushed coal or coral, when in practical use quickly became so clogged with mucus and coagulated blood that the frequent cleansing of the strainer during operation became necessary. This fact led Sir Henry Thompson to say, in THE LANCET (1883), that "all the perforated tubes and strainers get so blocked with débris (as I found long since) in the human bladder—not with coal in water—as to be practically useless there." As Professor Bigelow had, in THE LANCET of Jan. 6th, 1883, presented a large-sized woodcut illustrative of the absolute inability of Sir Henry Thompson's then latest instrument to prevent the return of débris to the bladder, with ample descriptive text, it might be suggested that his opinions of perforated tubes and strainers had been somewhat modified by personal feeling. The accompanying accurate copy of a photograph of the perforated tube or strainer of Professor Bigelow's improved evacuator, taken at the close of an operation at St. Luke's Hospital not long since, will, however, go far to justify Sir Henry Thompson's statement. (Fig. 2.)

FIG. 2.

Showing tube blocked with mucus and coagulated blood.



In cases free from mucus and pus, and perfectly free from any admixture of blood with the water during operation, there will not be any noteworthy difficulty; but if there is a trace of blood present in the progress of the procedure, the perforated tube will inevitably and promptly become blocked, as in Fig. 2. The instrument was a good one for practical purposes before the addition of the perforated tube; but it was open to the objection, as shown, that débris was likely to be left in the bladder after operations with it. Save under very favourable conditions, or by the frequent cleansing during operation, the objection evidently remains.

Sir Henry Thompson's experiments and modifications finally culminated in an evacuator which equally in action prevented the return of débris, without being open to the objections made against Professor Bigelow's instrument. This improved aspirator was presented in the London LANCET of April 12th, 1884. (Fig. 3.) "The improvement consists in a light, loosely-hanging valve of fine wire attached by a simple hinge to the end of the evacuating tube, which terminates within the glass trap of the instrument. When pressure is made on the indiarubber globe, and the current flows by the evacuating catheter into the bladder, this light valve is driven close to the aperture, and no débris can leave the glass trap. When the pressure is removed, and the current returns from the bladder, the valve floats widely open, and permits the débris to enter unchecked. The wire valve is circular in form, and its border, being flat and thin and about the tenth of an inch wide, is delicately sensitive to the movements of the current, and responds to the slightest impulse of the hand on the indiarubber globe." "But," Sir Henry Thompson further remarks, "I am quite satisfied that with my last published aspirator (the one so elaborately criticised by Professor Bigelow in THE LANCET of Jan. 6th, 1883), as well as with the form now described, no débris returns to the bladder if the instrument is properly used, when, of course, the valve is unnecessary. Few persons are aware that very slight but quickly-made pressure on the globe, sufficing to transmit only six or eight drachms of fluid into the bladder, generally removes more débris than a powerful impulse which transmits at one act all the fluid contents of the globe, or nearly so. When employed in the manner last named the valve becomes useful, and only then is it required."

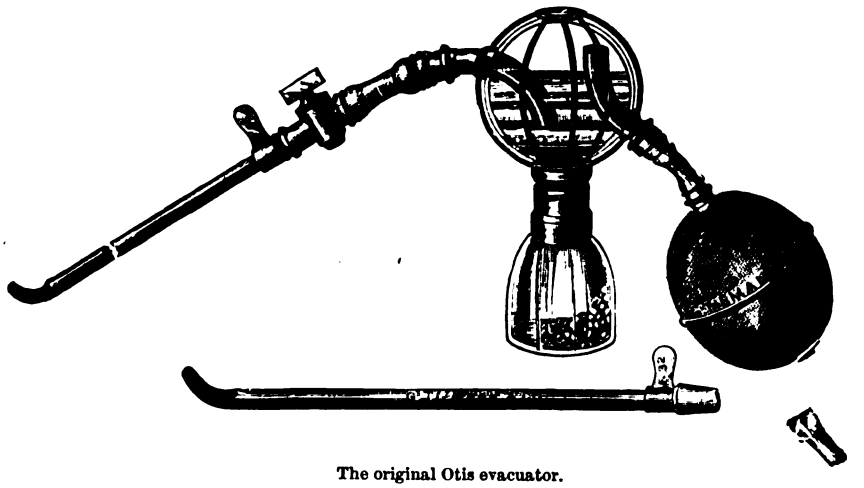
At the commencement of the evacuator contest I was using very satisfactorily the original Bigelow instrument, and was, at the time of the notable discussion at the London International Congress of 1881, under the impression that it was the best then in use. During that discussion, Sir Henry Thompson accorded to me a fair share of the honour of contributing something towards the ultimate success of the operation of removal of vesical calculi at a single sitting. My distinguished countryman, Professor Bigelow, however, neglected to give me the credit of the previous discovery of the normal urethral calibre, through which alone the rapid evacuation became possible. Not desiring to assert my claim as a grievance, I determined, if possible, to invent another evacuator, and, in describing it, to write the history of evacuators in general; in this I proposed, while according honour where honour was due, to take what I believed to be my legitimate place in the preliminary history of litholapaxy.

Two years afterwards—viz., in November, 1883—I presented and demonstrated my first evacuator at a meeting of the New York Academy of Medicine, and read a paper in

FIG. 3.

Sir Henry Thompson's instrument (improved), 1889. Weighs 27½ oz. troy empty, 40 oz. filled.

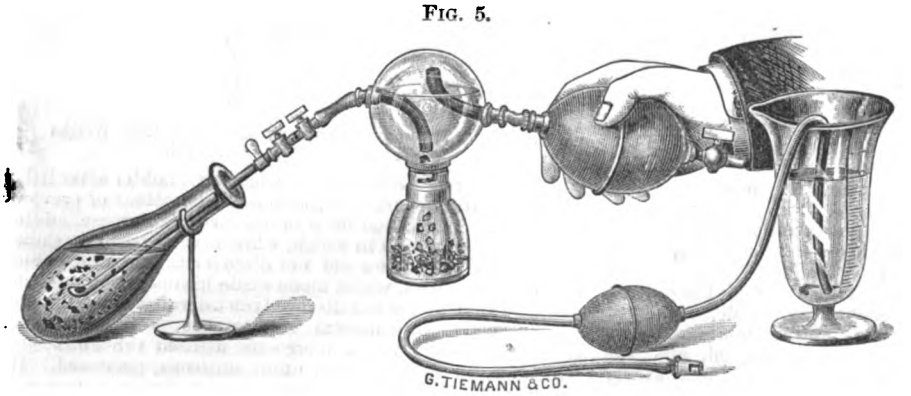
which "the removal of débris from the bladder after lithotrity" was fully considered, with representations of previous instruments which had been in use for that purpose, adding those of my own, and in which, while it was distinctly shown that Professor Bigelow did not discover the increased capacity of the urethra, which alone made his operation possible, and also that he did not discover the tolerance of the bladder to prolonged instrumental interference, yet, as I there claimed, "he did much more—he utilised the knowledge which he, in common with other surgeons, possessed. He had the inspiration to conceive of its value as a factor in a great life-saving operation. He seized my demonstration of an average urethral calibre of 32 mm. in circumference. He joined it with his knowledge of the toleration of the bladder to legitimate surgical procedures, and litholapaxy was born. He had the courage, the surgical knowledge, the skill, the inventive mechanical genius, and the perseverance to carry it, *vi et armis*, to a successful maturity, thus finally achieving one of the most brilliant surgical triumphs of modern times."



My own instrument was constructed on an entirely different plan from those of both Professor Bigelow and Sir Henry Thompson. Having appreciated the difficulties of overcoming the alleged faults of both, I endeavoured to accomplish evacuation without return of the débris, independently of traps, valves, or strainers. This was effected by a simple breaking of the currents to and from the bladder, so that the débris should be released *in transitu*, and drop

Digitized by Google

down into a receiver arranged to be a perfectly dead point. (Fig. 4.)



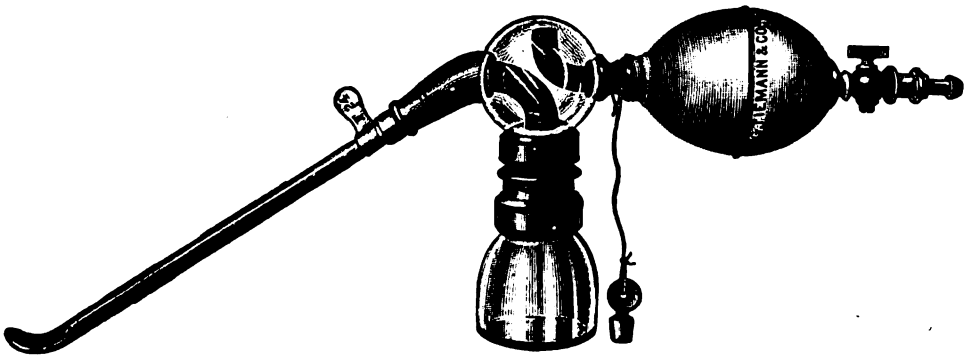
In its practical working it was found fully equal in its evacuating power to the improved instrument of Bigelow, with the advantage that, without trap or strainer, no débris was returned to the bladder. It was found, however, that under circumstances where during the operation it became desirable to introduce an additional amount of water into the bladder this could only be effected with considerable inconvenience, much greater than in Professor Bigelow's or Sir Henry Thompson's instruments. In 1885, therefore, a tap and stopcock were added at the end of the rubber bulb, as shown in Fig. 5, so that, when it was found desirable to introduce additional water into the bladder, this was done with great ease by attaching the discharge pipe of the Davidson's syringe to a stopcock, while the supply end is immersed in a vessel (preferably a large glass graduate) filled with water at a proper temperature. The easy attachment and detachment of the Davidson's syringe allow any desired amount of fluid to be introduced into the bladder without delay or inconvenience. With this addition the instrument did most satisfactory service in my hands during the following two years. The only real embarrassment which was found in the use of this evacuator was from the weight and inconvenience of manipulation of the two stopcocks, which objection obtained equally in the instruments of Sir Henry Thompson and Professor Bigelow. At the suggestion of my son, Dr. Wm. K. Otis, who had noticed the greater lightness of the evacuator of Dr. Ultzmann of Vienna, I substituted hard rubber fittings similar to his; and in the course of experimentation which this change suggested, removal of all intermediate connexions between the glass reservoir, the rubber bulb, and the evacuating catheter was found to decrease the weight and add to the ease in handling the instrument. It was then discovered that a stopcock was not necessary to prevent the water from flowing from the evacuator, this being effected by atmospheric pressure alone in any position which the handling of the instrument required, and that only when laying it down was any water liable to run out. For use in this event a simple plug of hard rubber attached by a string was alone necessary. These important changes decreased the weight to such an extent that when filled my perfected evacuator weighed six ounces less than Professor Bigelow's when empty. The successful elimination of one stopcock, previously supposed to be the most important, and still absolutely essential in the instruments of both Prof. Bigelow and Sir Henry Thompson, directed attention to the possibility of getting rid of the remaining stopcock on the evacuating tube, which seemed desirable in order to prevent loss of water while attaching the evacuator to it after the crushing. It was ascertained in actual practice that, by changing the routine of operation a little, this stopcock was also wholly unnecessary. Instead of attaching the evacuator to the evacuating tube immediately upon its introduction into the bladder after crushing, the fluid was allowed to flow out, carrying with it all the fragments that could thus be washed out; then, deliberately attaching the evacuator to the tube, the desired amount of water for working the instrument easily, was introduced by means of the Davidson's syringe, which was connected with the rubber bulb. The syringe was then attached and the evacuation deliberately proceeded with. It was not found necessary to press the end of the evacuating tube to the extent of depressing the bladder floor so as to make the portion with which it is in contact the lowest point, as advised in using the evacuator of Professor Bigelow, but the current was sufficiently strong to draw out the débris if the tube was simply well introduced into the bladder cavity. Among the tests which were originally made to prove that the receiver was a perfectly dead point, and that fragments once deposited in it were thus entirely out of the influence of the currents passing to and fro during evacuation, was that of filling my evacuator completely as for ordinary use, then detaching the reservoir, emptying it, refilling it with glycerine, and then reconnecting it with the reservoir. A small quantity of crushed coral (which more nearly resembles vesical calculus than coal) was introduced into an ordinary soda-water bottle, and this was half filled with water to which a little ink had been added. On working the bulb, the fluid thus coloured was seen to pass back and forth through the reservoir, but not in the least mixing with the glycerine, while the coral was drawn out of the bladder in the inky current, and, receiving its impulse and direction from the discharge-pipe, was disengaged from the coloured medium and, dropping down through the clear glycerine, was deposited at the bottom of the receiver. This experiment, which proves in a striking manner the perfect retention of the débris in the receiver during evacuation, was subsequently found to work admirably in actual practice; and, in all operations for the last two years where blood was present in sufficient quantity to obscure the fluid, I have used glycerine with great satisfaction. Without it, it

FIG. 4.

The original Otis evacuator.

FIG. 5.

The Otis evacuator, improved.



Digitized by Google

will occasionally be difficult, and sometimes impossible, to tell whether the evacuation of the débris is proceeding satisfactorily without disengaging and emptying the receiver.

The changes which have been made in the old instrument are as follows:—1. Removal of all stopcocks. 2. Removal of tubing between the bulb and globe, and between the globe and evacuating tube, thus making the instrument more compact and the distance from the bladder to the receiver the shortest possible. 3. Introduction of hard rubber in place of metal wherever possible, giving the utmost lightness. 4. Making the tube apertures in the globe oval instead of round (Dr. W. K. Otis's suggestion), and thus giving the greatest security against their fitting loosely and leaking. 5. Increasing the calibre of the evacuating tube where it enters the globe, thus securing a greater rapidity in delivery.

It is now claimed that this latest evacuator (Fig. 6) presents the following advantages over all other instruments now in use:—1. Perfect trapping of all fragments without the use of any form of valves, perforated tubes, or strainers. 2. Shortest possible route of fragments from the bladder to the receiver. 3. Absence of all stopcocks between the bladder and receiver. 4. Ease of filling and perfect control of the amount of water in the bladder during evacuation. 5. Lightness, compactness, power, and facility of manipulation. 6. The fragments being visible from the moment of leaving the tube until removed from the receiver, it can be seen that they do not return to the bladder.

FIG. 6.

The perfected Otis evacuator. Holds 8 oz. Weighs 10 oz. empty, 18 oz. filled.

I may state that the original Otis evacuator was manufactured by Messrs. George Tiemann and Co. (surgical instrument makers of New York), who with much pains and skill have aided me in the succeeding changes necessary to bring the instrument finally to its present state of perfection.

New York.

A STUDY ON LEPROSY:

BEING A SUMMARY OF OBSERVATIONS MADE DURING A RESIDENCE IN PALESTINE.[1]

BY DR. MAX SANDRECZKI,

DIRECTOR OF THE HOSPITAL FOR CHILDREN AT JERUSALEM.

Translated by EDWARD ATKINSON, *Honorary Surgeon to the General Infirmary at Leeds.*

AN article of such a nature as I here present to dermatologists, specialists, and philanthropists cannot pretend to be a scientific dissertation, or even a complete recital of all the phases which the horrible malady with which we are about to concern ourselves passes through. My aim is infinitely more modest. I desire, as simply as possible, to impart to my colleagues the observations and experiences which I have made during my residence in Palestine, and at the same time to gain the attention of both colleagues and philanthropists to the possibility there may be of combating with success the terrible scourge of leprosy.

The disease which bears the name of "leprosy" has been known from the most remote times. We find already in the Bible indications and data, more or less exact, of the leprosy called the "white,"[2] *morphœa, alba, mosaica,* and also of the leprosy named "tuberculous," nodosa, tuberculosa, mutilans,[3] also in Celsus,[4] and Pliny's Lucretia. Nowadays, one meets in Palestine and at Jerusalem (excepting only rare and isolated cases) with none but the tuberculous, mutilating leprosy, accompanied, according to the individual case, with anæsthesia or analgesia. Notwithstanding the total absence in Palestine of medical statistics, it is allowable to estimate at about 600 the number of lepers inhabiting the towns and villages of this country. At Jerusalem they live in common in a domicile assigned to them by the municipality. Immediately that symptoms of leprosy are apparent in a person he is promptly excluded from his village, separated from his family, and must go to the nearest town, in order to live on alms and on what his relatives bring to him. It happened formerly that some individuals suffering from another malady—e.g., from syphilis,—but accused by their enemies of being leprous, were doomed to expatriation. Such events no longer occur, because when a similar case arises the inculpated submits himself to examination by the doctors. There exists at Jerusalem a large hospice for lepers, founded under the auspices of the Moravian Brethren, and destined to collect together, if possible, all the lepers of the country, with the intention of bringing about the disappearance of this affection by means of a process of exclusion and isolation. The founders and patrons of this institute hope to attain their end, which, however, is rather philanthropic and religious than scientific. It is, at the same time, useful to draw attention to the fact that, as the Government has no intention to let these poor unfortunates be shut up, or to separate married people by force, this great establishment has but a very limited *clientèle*, amongst which there are also some syphilitic cases. As to my opinion, I am obliged to declare that the result of my researches gives me the conviction that leprosy is by no means contagious, and that consequently the exclusion and isolation of the patients is both a useless and a cruel measure. If leprosy were contagious in the sense in which one understands it, the staff of the above-named hospice, where men and women devote themselves to the care of the lepers, would be likely to suffer from this daily contact, dressing of wounds, washing of linen, &c. During the twenty-five years the hospice has existed not one of the *employés* has suffered either from any infection or any contagion whatever. Since the existence of this hospice, and by the example given to the public of not fearing the leprosy, lepers are permitted to enter the towns and the bazaars, and it has not been proved that there is any increase of leprosy. The same fact is pointed to in numerous places in the East, where leprosy ought to be followed by an excessive propagation among the lower classes if it were truly contagious. Eleven years ago I had

in my Children's Hospital, for four years, a leprous boy, and although he was always in contact with the other patients and domestics, and often with my own children and myself, there was never any contagion, even though there were always several other cases of leprosy with wounds in the hospital. Medical literature also tells us that there have been persons who have for long together lain in the same bed with the leprous, and have even cohabited with leprous women, to prove whether there were infection or contagion, and the result was negative. In Japan, lepers are free to live and to go where they will, and leprosy, instead of increasing, has even diminished, according to the report of Dr. Sissu, chief physician to the Prince of Satsuma, and of Professor Balz of the University of Tokio.

The heredity of leprosy is not constant; it sometimes appears to be in a manner intermittent—that is to say, neglecting one generation to appear again in the next. It is so among the lepers of Palestine. I have seen many children of lepers who were in no way tainted by the disease of their parents. Chinese physicians only admit one mode of propagation of the disease (*la voie héréditaire ou sexuelle*), but I have examined the wives of lepers in perfect health. Lepers whom I have questioned have assured me that inheritance is not constant, and they have told me that as soon as the leprosy is well developed procreation ceases. As everywhere else, hereditary propagation is difficult to prove, seeing that leprosy is only developed (as a rule) at the age of puberty. I have seen some cases at the age of five and six years. I have never seen it in the newly born. Dr. Zambaco of Constantinople tells us that leprosy shows itself even at birth. If children remain under bad hygienic conditions, which it is well known tend to produce leprosy, it is evident the disease might easily develop without being hereditary of necessity. As to persons favourable to the propagation of leprosy, I am in a position to state that in all Palestine, and especially in Jerusalem, I have never met with a single case among the inhabitants of towns, or of those who belong to the well-to-do classes. On the contrary, in China and Japan, in the Canaries and Sandwich Islands, even the rich are susceptible of becoming lepers. After the Crusades, in the middle ages, there were lepers even among the seigneurs.

Leprosy in Palestine is developed by insanitary conditions, of which I will enumerate the chief: impure air—the tainted exhalations which prevail in the villages and unhealthy habitations of the fellaheen; the water-supply, often stagnant and deteriorated; the oil and fat (used for food), rancid, or salted beyond measure; olives and cheese in a state of decomposition; meat rotten, or coming from animals diseased, or worse still. Add to all this extreme uncleanliness the utter absence of skin-action, and then one may easily explain derangements in the tissues of the skin, in the lymphatic and ganglionic systems, and, in a word, complete disorder of all the nutritive functions. The rapid changes of temperature in this country, the difference between the dryness of the day and the moisture and cold of the nights, necessarily affect the reciprocal action of the skin and of the lungs; but this and its interruption have not yet been sufficiently studied either by observation or experiment. I have, however, been able to prove, in a great number of lepers, the gradual and sometimes complete cessation of perspiration. Excess in venery, which the fellaheen practise, greatly augments, no doubt, their predisposition, by weakening the body. After numerous inquiries, I am of the opinion that chronic intermittent fever plays a part in the development of the disease. Chinese physicians, and Japanese also, mention that, besides the above-named causes, variability of climate is favourable to its evolution. Hindoo specialists also say as much. I have found it stated, in a report upon the lepra caspica, that the people who furnish the majority of candidates for leprosy suffer much from intermittent fever. Sweat contains various acids, urea, and many bacteria. If these excretions are retained by the want of perspiration, is it not probable that they would cause derangement of the tegumentary structures, and is it not remarkable that leprosy shows itself chiefly in those parts of the body which are most exposed to the air. To sum up, then, it must be concluded that leprosy is developed indigenously, spontaneously, under conditions and predispositions known and unknown, especially when there is general organic waste (*déchéance*) of an individual or of a people.

As to the possibility of cure, one may say without fear of contradiction that among adults it is excluded. Throughout the whole extent of the literature which I have studied upon this point I have only found a few isolated cases the authenticity of which seemed to me to be established. The historians of leprosy are in accord in saying that all measures of restraint, such as isolation, exclusion, forbidding to marry, and other cruelties, have not tended to the annihilation of leprosy. Whenever the disease has diminished or has disappeared, it is certainly hygiene and civilisation which have brought it about. If one might believe the sheiks of the villages (statistics again being unfortunately defective), leprosy even in Palestine is in course of receding under the influence of civilisation and of the amelioration of the general circumstances of the population. It is yet necessary to create for the people better conditions of existence, and to establish a sanitary regimen even in the smallest hamlets. Taking account of all these observations and of my own researches, I have arrived at the conclusion that leprosy is curable in children if it is taken in time—that is to say, when it begins to show itself. In order to be able to base my opinion upon a fact, I received into my Hospital for Children, and cared for, a young boy ten years of age attacked by leprosy and already in a somewhat advanced stage. Examination of this boy gave the following results: Colour of the face sickly brownish (*brunâtre malsaine*); the eyelids, nose, and ears tumid; tubercles, of sizes varying from a pea to a hazel-nut, on the forehead, nose, and eyelids, of which some were in a state of suppuration; the eyes weeping; nose running; palate and pharynx sprinkled with small tubercles, and slight points of ulceration; the breath malodorous; and, lastly, a hoarse and nasal voice. On the hands were contracted cicatrices caused by ulcers. His whole system was enfeebled. He suffered from intermittent fever, and did not perspire even when working in the greatest heat. Sensibility of the face, arms, and hands was much diminished, and he complained of severe deep pains in his arms and in his muscles. After a treatment which extended over a space of four years, the young man could be sent home cured. He now earns his living as a labourer, and lives with his parents. The treatment followed may be designated simply as *hygièno-tonique*, internal as well as external: mineral baths, exercise, gymnastics, work in the open air, without the use of any specific. The sheiks of his village recognised the young man as cured, and have satisfied themselves that the malady was arrested. Several of my European colleagues also are convinced of his cure. After the cure the perspiration was abundant, and the intermittent fever ceased.

A German specialist, Professor Staeser, has declared that he attaches no importance to hospices and prisons for lepers with a view to the annihilation of leprosy; but that, on the other hand, asylums for children have every chance of giving good results. A treatment like that of our leprous boy is naturally very expensive; it requires much patience, and lasts for years; however, it seems to me that, all considered, the result obtained balances the cost. If leprous children can be cured and remain healthy, the next generation will most likely be so also. But to advance securely it will be necessary to make repeated experiments, and certainly the subjects will not be wanting. Up to the present time I have received no subsidy or aid, either from the Ottoman Government or from the municipality, to place me in a position to treat other leprous children. My hospital, with 200 in-patients per annum, treated gratuitously, costs me enough already. These lines will perhaps have the effect of attracting the notice of some men of science or philanthropists to this interesting subject. I am obliged to confess that I have not had an opportunity of making a special study of the bacillus of leprosy. The discovery of the bacillus has not hitherto advanced the curing of leprosy. Neither the transmissibility nor the mode of propagation has been demonstrated. Unfortunately we are not permitted here to make dissections, and it is almost impossible to procure objects for the microscope. In conclusion, I would remark that if the bacilli cause leprosy and propagate it from one person to another, how can we explain the long latent period—the repose of the bacillus for years? Is it not probable that the human body, more and more degenerated by years of misery and by every sort of hurtful influence, becomes the soil favourable for the development and culture of the bacillus?

NOTE ON LEPROSY IN NORWAY AND THEIR SPECIAL HOSPITALS.

BY HERCULES MAC DONNELL, M.D.,
SURGEON TO THE COUNTY LOUTH INFIRMARY, DUNDALK, ETC.

HAVING just returned from visiting nearly all the leper hospitals in Norway, a few remarks concerning them may be of interest to the readers of THE LANCET. When I left, in June, the leper craze in England had assumed an acute form; when I returned, a month later, it had apparently died out. It is reported (whether truly or not I am unable to say) that an eminent member of the profession has started for the "land of the midnight sun," with the avowed object of collecting materials for an article in one of our leading monthly magazines on this savoury subject. To my mind, discussion on such subjects in the lay press is to be deprecated. If, however, the public crave such pabulum, it is well that it should be supplied by an eminent peripatetic vendor of such articles; but let us hope that we may be spared pen-and-ink sketches or photographs of the various phases of this loathsome affection.

Having arrived at Bergen on June 19th, Dr. Christie kindly appointed the next morning to show me round the Special Hospital and Asylum. The hospital is pleasantly situated about a mile and a half from the town, in close proximity to one of the general hospitals. There were sixty-two cases under treatment in various stages of the disease. The nursing seemed inefficient, the wards not over clean, and the patients had that peculiarly sad, downcast air which is always visible where large numbers of lepers are gathered together. In all the hospitals and asylums I visited, the physicians were thoroughly conversant with every detail relating to their special subject: not only treatment but pathology and statistics receive exhaustive care. The Government has gone to great pains and expense in publishing returns and maps with coloured areas showing the infected districts and the progress of the disease during decennial periods. By means of these maps the advance which hygiene and segregation have made in diminishing the disease can be traced with rapidity. In 1876 there were some 1300 lepers; the last return shows only 846. Dr. Christie is of opinion that about 10 per cent. of non-tubercular cases are curable. He has given up the gurjun-oil treatment, and relies mainly on the salicylates of soda and potass internally. Excoriated surfaces are treated generally with ointments containing salicylate of soda or iodoform, and solid nitrate of silver is used where fissures are deep and difficult to heal. I saw one remarkable case of elevated flat ulcer on the sole of an atrophied foot, which had resisted all treatment for a period of six months.

Dr. Christie then brought me to the Leper Asylum. It is an old building, with a curious chapel in the central courtyard dating from the fifteenth century. There being no isolation law in Norway, the authorities are unable to compel lepers to leave their homes. They are, however, forbidden to marry, and at certain central places—such as Bergen—asylums are open for their reception, where they are paid 40 ore (5½*d.*) daily. The inmates have to supply their own food out of this allowance; they have each a separate apartment, and are subject to few restrictions. In Bergen Asylum they are permitted to work, and, when not too ill, to vend their wares in the open market. Dr. Christie does not believe in the contagiousness of leprosy, and in Bergen it is quite common to see sufferers walking about and offering goods for sale. In other places—such as Molde—they do not allow lepers the same latitude of intercourse.

At Molde, Dr. Kaurin received me with the utmost courtesy—as, indeed, did all my Norwegian *confrères*. Nowhere did I perceive that any credence was attached to the fish-origin theory. Dr. Kaurin's writings on this special subject are widely known abroad. He has contributed some classical papers to the chief French work on leprosy, and his tabular statistics are most valuable. He holds more pronounced views on its contagiousness than those of his colleagues further south. He does not permit the sale of work, and lays much stress on the necessity of patients remaining a great deal in the open air and having ample ventilation in all wards and day rooms. The climate of Molde is not so severe in winter as Bergen or Trondhjem, and, though the district is one where leprosy is extremely prevalent, the result of semi-isolation and treatment is most encouraging. The hospital contained seventy-four patients. It is a fine building, with large and well-ventilated wards containing from three to nine beds, lofty corridors, and the kitchen and offices scrupulously clean. The entire hospital conveyed the impression of being well managed, that no necessary expense was spared, and that the patients were well cared for. Schooling and instruction in various ways are provided for such of the inmates as desire it. There is a bright well-lit chapel in the hospital, and the grounds for recreation are ample and well kept.

At Trondhjem, the Spedalsk Hospital is situated on a high plateau about two miles and a half from the town. At my visit there were seventy-eight patients under treatment. The building is large, having a long central corridor, off which the wards open. The wards are high and airy, but there was a most decided want of cleanliness throughout. The situation left nothing to be desired; but I cannot say I was impressed with the general arrangements. Much might be done at Trondhjem and Bergen to render the surroundings more cheerful and the lives of the inmates less irksome. There seemed to be a total absence of interest by the external world, and, in consequence, a daily routine dreary and depressing in the extreme.

The three places I have alluded to are the main centres for the treatment and semi-isolation of lepers in Norway. The steps which have been taken have proved most successful, and it is now merely a matter of time for the disease to be almost stamped out. All the specialists agree that hygiene carried out in the homes, with special attention to personal cleanliness and proper food, would hasten this desirable end; but amongst so democratic a people it is difficult to pass any law trenching on the liberty of the subject. The difficulty of inspection and the insistance on sanitary measures are wellnigh impossible, owing to the great distances patients live from centres of civilisation and the total interruption of all communication during the long winter months. The main factors in producing the disease (besides heredity) are filthy habits, bad food (mostly fish, salted or dried), the absence of sunlight for many months, foul air in stuffy and smoky cabins, insufficient heat and clothing, and the almost entire absence of green food or flesh meat. Compulsory isolation can alone deal rapidly with such a condition of things. The Storthing has been appealed to in vain by sanitary reformers for more stringent measures than prevail at present. The existing arrangements are slowly and gradually working a vast improvement. It is probable a time may come when they shall have accomplished all the improvement they are capable of effecting, and a residuum of cases will remain. When that times arrives, the sturdy common sense of the nation will insist on such further measures of restriction as may be necessary to stamp out completely the disease, for one and all are agreed that stamped out it must be.

Dundalk.

ON JOINT SCRAPING; WITH TABLE OF CASES TREATED.[1]

BY H. A. LEDIARD, F.R.C.S. ENG.,
SURGEON TO THE CUMBERLAND INFIRMARY.

ON Nov. 1st, 1882, a boy aged six came under my care at the Cumberland Infirmary with disease of the knee-joint. The case is recorded fully in the writing of Dr. Leith Waters, then house surgeon, and I give a brief abstract of it as an introduction to what is to follow on the subject of joint scraping. The knee was flexed and tender; a sinus existed on the outer side of the thigh, from which from half an ounce to an ounce of pus drained daily; a probe did not enter the joint. The boy was pale and emaciated. The disease was traced to an injury some six weeks previously. On Nov. 18th an ordinary semilunar incision was made as for excision of the joint through the patellar ligament, and the posterior part of the internal condyle of the femur was found softened and carious; it was

[1] Paper read before the Carlisle Medical Society, Dec. 13th, 1888.

Digitized by Google

scraped, the scraping of the softened tissue resulting in the formation of a hollow in the substance of the condyle; the crucial ligaments were softened and infiltrated, but the joint was otherwise in a fair state of health. The wound was stitched up and a back splint applied. At the end of March, 1883, the joint was put up in a stiff bandage, and the boy went home wonderfully changed in appearance for the better. The lad never came back as desired, but during August, 1887, I found him out, and heard that the joint had discharged for eighteen months after he got home, and then healed up. I found ankylosis present at a bad angle. The upshot of the surgical procedure in this case was a surprise to me. I had not intended to stop short of excision of the entire joint; but, finding the disease so localised, it seems that we determined at the time to try what scraping out the diseased part would do.

In the spring of 1887 I heard from Mr. H. W. Page, of St. Mary's Hospital, that a new method of dealing with joints was being tried. He called it "arthrectomy," the chief feature of the operation being that all disease, whether in synovial membrane, cartilage, or bone, was carefully removed with a sharp spoon, and it is entirely due to my conversation with Mr. Page on this subject that I am in a position to draw attention to joint scraping.

It appears to me that in the treatment of joint affections, as in the treatment of many surgical affections, efforts are being made to break away from the routine treatment of past years. Formerly amputation was then the only treatment for diseased joints; afterwards came excision. Short as has been the reign of excision, and hardly perfected in many of the needful appliances, we have been led to believe that excision has been resorted to too freely, and that rest follows the rule of a "complete removal of diseased parts" as essential to success in excision of the knee. Bleeding from the cut surfaces of the bones is sometimes very troublesome and difficult to arrest. Given an ordinary excision of the knee, with a moderate amount of bone removed, good position, and absence of much hæmorrhage, and yet the result is often amputation. This may in some instances be due to the entire disease not having been taken away; bone surfaces are perhaps clear, and much synovial gelatinous degeneration also cut away, but much that escapes the eye may be stitched up in the wound and lead to failure—at least, I am sure that it has been so with me. "All portions of diseased synovial structure that can be safely dissected off should be removed," said the late Mr. Spence, a remark which seems to imply a difficulty in dissecting everything away.

In the operation of scraping out a joint, the principle favoured by Mr. Bryant—viz., "the least sacrifice of parts"—is held in view, and as such should at least command the attention of all surgeons. Tedious as it may be to scrape out a large joint, hand-aching, and very dull to an onlooker, yet the saving of a limb is the goal to be kept in view. Taking the cases seriatim, I will glance at them as briefly as possible. (See accompanying table.)

1. Hannah B——, aged twenty. Knee diseased eight years. No sinus. On opening the joint, the cartilage was almost all gone, and the bone diseased throughout the joint. The case did well. I should add that the crucial ligaments were left. The patient can walk, though the knee is stiff. Osseous ankylosis is present, but there is no shortening. Patella left. (Exhibited to Society.)

2. Jane P——, aged three. Pus in knee-joint, with

and drainage are all that are necessary to cure many cases of diseased joints; this, I take it, is the outcome of Sir Joseph Lister's work. The last suggestion which has been put into practice seems to me a sort of compromise between excision and rest with drainage. The joint is to be laid open and the diseased parts cleared out, with a hope that ankylosis or perhaps even a movable joint may result; at any rate, excision of the diseased joint by a less severe method than that which succeeded amputation. In any case the movement is one which every surgeon will welcome, and it is one which will ultimately mark the last quarter of the nineteenth century.

First a word on the difficulties attending excision of the knee; for difficulties there are which have been recognised on all sides, or else why so much ingenuity displayed upon splints for use after operation? I cannot say how many methods I have seen, from Dr. P. H. Watson's plaster and iron rods to Mr. Morrant Baker's skewers for fixing the bones. The difficulty of fixing the ends of the femur and tibia and obtaining ankylosis in good position is due to the fact that excision thoroughly loosens the entire joint; frequently, in order to obtain good position, more bone is removed than is really needful—as where there is subluxation or semi-flexion. Sometimes several slices of bone require removal before the limb can be put on a back splint, and this means severance of all ligamentous attachment between the bones, lateral and posterior. For subluxated joints it is probable that the bones must still be sliced away, in many cases unnecessarily so far as the disease goes.

I venture to express an opinion that it is occasionally difficult to tell exactly where diseased tissues end and healthy begin, especially where bone is concerned; hence, rather than leave any doubtful tissue behind, the surgeon pulpy disease. Little or no change in cartilage. No sinus. The crucial ligaments were sacrificed during the scraping. The case did well, and osseous ankylosis at a slight angle resulted. Patella left.

3. The next case was an ankle. Mary J. B——, aged five. Entire ankle diseased, the joint being soft and swollen, with numerous sinuses, which discharged pus freely. The entire joint was scraped out, the astragalus included. The child was very strumous and weak. She ultimately did well, and had a sound joint, though the foot was much shortened. (Exhibited to Society.)

4. The next case was knee No. 3. Elizabeth S——, aged nine. The knee was subluxated, and had numerous sinuses. Limb attenuated. General health not broken down. On scraping, pulp and pus were present; cartilages destroyed; osseous surfaces soft; patella scraped away; crucial ligaments gone; femoral epiphyses scraped away. This case was in the balance for a long while, was finally amputated on Aug. 17th, 1888, and recovery resulted.

5. The next case was another knee. Mary Jane G—— (date Aug. 29th, 1887). No sinuses. Knee enlarged. The child was puny, and had spinal curvature. On scraping, pulpy disease was present; no pus; commencing ulceration of cartilage; bone subjacent red and soft; epiphysial cartilages exposed; one crucial ligament left standing. The case took a long time to recover, but did well. The child is paraplegic from spinal disease.

6. The next case was a hip in a delicate boy of eight years of age. There was a large abscess of the hip-joint; no sinus existed. The joint was scraped out. Head of femur soft; scraped away. Acetabulum scraped out. The case hung in the balance for some months, but death occurred

Digitized by Google

from brain disease in March, 1888. This was the first hip case operated on.

7. The seventh case was another knee. Frederick G——, aged twenty-two. The disease had existed eight years; no sinus. On scraping the joint I cut away the patella at once. Cartilages of joint diseased and loosened; underlying bone soft; crucial ligaments left. The case did not do well, and amputation was performed on June 6th, 1888.

8. The next case was the second hip operated on—an unfavourable one for any treatment. An abscess had been opened in the thigh, and the scraping was secondary to this by two months. The head and neck of the bone were scraped away, and the acetabulum scraped out. I thought it possible that it might even be perforated. The case did badly; abscesses formed repeatedly; high temperature was kept up, and death by hæmorrhage ended the case in October, 1888, five months after the scraping.

9. This case was the second ankle. Abscesses of the joint had been opened previously. The limb was wasted and the boy rather hectic. His age was twelve. The ankle-joint was filled with pulp and pus; the osseous parts were soft, and the cartilages gone. The astragalus in this case also was scraped away. The case did fairly for a time, but continued pain and failure to heal necessitated amputation on Sept. 12th, 1888, recovery ensuing. (Died later on with phthisis.)

I have thus operated on six knees, have lost no patients, but had to amputate two of them. I have operated on two ankles, one of which did well, and the other was amputated. I have had two unsuccessful and fatal cases of hip disease, where scraping was tried. These two cases would not have done well or better by ordinary excision, and were certainly unsuitable for hip amputation.

Evidences of failure after scraping will be found, clinically, in continuation of more or less elevation of the temperature, general failure of the patient's nutrition, persistence of pain on palpation of joint, and failure in obtaining a certain amount of ankylosis. Thus, the ankle scraped out on June 11th, 1888, was amputated on Sept. 12th following, the joint being as loose as a healthy joint, and perhaps looser. The temperature was always up during a part of the twenty-four hours. There were numerous discharging and unhealthy-looking sinuses; there was tenderness on pressure all over the joint; and the nutrition of the limb was declining. It is somewhat difficult to say when interference is called for in cases where scraping has been tried; but I think that six or eight weeks will probably show how matters are likely to turn out. It is true that I have one case which was not healed for a long time, but there was not that association of those evidences of failure which I have already alluded to. The gradual stiffening of the joint, absence of pain, a normal or nearly normal temperature, and an improved condition of general health are the symptoms which are to be looked for where success is to be expected.

If this method is proved to be of permanent value, and if the joints scraped out remain sound and good, the question arises naturally, to what joints is scraping limited? If the knee and the ankle are joints to which scraping can be applied, what about other joints which are so frequently diseased? It appears to me that at the elbow scraping would be followed by ankylosis, which would render the arm probably useless; and I question whether the free mobility obtained after excision of the elbow in the usual manner could ever be obtained by scraping. This is, however, an open question, and I have not as yet been tempted to scrape out an elbow joint. My two cases of hip disease are not encouraging, but I can say this, that the operations caused far less shock, hæmorrhage, and disturbance of parts than excision would have done. I am not sanguine that movement will be obtained even after partial scraping of a joint, and am inclined to think that ankylosis is the end to to be kept in view.

In conclusion, I desire to state distinctly that the number of cases operated is insufficient to justify any dogmatic assertion as to the future of scraping, but that, as a substitute for excision, it is very hopeful and worthy of trial; that the shock of the operation is not to be compared to that of excision; that the hæmorrhage is less than that of excision; the loosening of the joint is markedly less; the retentive apparatus necessary is but slight compared to that needful after excision; and the pain of dressing subsequently is trivial by comparison. In some instances where the surgeon is prepared to excise, he may, after the joint is exposed, find that the disease is limited to one part of the joint, as in the first case I treated by scraping, and if this is so the case may be conducted to a happy issue without subjecting the patient to the greater risk of entire excision of the joint.

Carlisle.

FULMINATING PYO-HÆMOTHORAX IN AN INFANT AGED EIGHT MONTHS.

By ANGEL MONEY, M.D., F.R.C.P.,
ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN.

THE rarity of this affection in infants under the age of twelve months, and the difficulty of distinguishing it at the outset from simple intense broncho-pneumonia, constitute the *raison d'être* for the publication of the case.

The patient was a female child, aged four months when first seen on Sept. 14th, 1888. The interest of the case does not really begin till the morning of Jan. 20th, 1889, when I was called to see the child because of the state of her breathing. She had suffered from a catarrh during the past four or five days, but on the night of Jan. 19th she was in a state of sound sleep, with a normal temperature, and breathing 24 to the minute; this proved to be a calm before the storm. On the 20th, at 9 o'clock, the breathing varied from 56 to 72 per minute, and the expiratory sound was panting, with a well-marked pause between inspiration and expiration (so-called expiratory respiration). The temperature was 104·2°; the lips pale and slightly blue; the alæ nasi working, but not the sterno-mastoids; the pulse was 168. *The child screamed at the slightest touch, and especially when lifted up* in such a way as to stretch the trunk; the right back and side were harder than the left; there were dulness, tubular breathing, and sharp râle at the right base behind. This side was ordered to be poulticed and an ice-bag applied to the head. The abdomen was normal. There was no retraction of the head, but the child had vomited once. On Jan. 21st there was no improvement, the dulness at the right lower half of the chest had increased, and there was some sensation of resistance on percussion; the rate of the pulse and breathing had increased; the heart's apex beat was in the fifth space, a quarter of an inch within the nipple line; the left sterno-mastoid was working very vigorously; the right side did not move so freely as the left; the supra-sternal notch and lower sides of the chest receded during inspiration; the abdomen apparently moved equally on the two sides; certainly there was no want of expansion during inspiration over the lower abdominal region. The case progressed from bad to worse, and on Wednesday night (23rd) matters seemed to be rapidly coming to an unfavourable climax; the whole of the right side was dull, and there were dulness and crepitation over the left lower lobe. On Thursday morning an exploring syringe was introduced in the right lower axilla and a sanguinolent fluid withdrawn; twelve ounces were at once evacuated by aspiration; after this the child, and the breathing, and the pulse were much improved, but towards the afternoon grew worse again, and it was evident from physical examination that air had gained access to the pleura, and that the lung had not expanded. Mr. Bilton Pollard then used the aspirator with marked temporary relief, and with the further withdrawal of a few ounces of the same sanguinolent fluid. But the relief was only temporary, and the next day it was decided to lay open the thorax and relieve the pressure caused by the pneumothorax on the lung and mediastinum. This was done with great benefit; the child recovered consciousness to a considerable extent, and the pulse and breathing were greatly improved. On Saturday (the 26th) vomiting and diarrhœa became more frequent, the brain again began to fail, the anterior fontanelle sank, and the child died at 3 P.M., in a state which Marshall Hall would have called "hydrocephaloid."

The necropsy was most instructive. The disease was limited entirely to the thorax, and there were no tuberculous formations either in the lungs or mediastinal glands; the pericardium and left pleura were healthy; the lower lobe of the lung was consolidated—*collapse-pneumonia* over its lower half; the right lung was much reduced in size, and occupied the groove by the side of the vertebræ; its

Digitized by Google

substance was hard and collapsed in the upper half, but friable and evidently pneumonic in the lower half. On section, muco-pus was seen in the tubes, and several small collections of pus were seen in the periphery of the consolidated lower lobe; one of these was in direct communication with the pleura by means of a widely patent fistula. The whole of the pleura was lined with a greyish-yellow lymph, and the subcutaneous and muscular tissues of the thoracic wall were infiltrated with a sanguinolent serum.

The history of the case was most probably this: After a catarrh severe broncho-pneumonia set in, and in places proceeded to the formation of small abscesses; one of these burst into the pleura, and set up pyo-hæmothorax of fulminating intensity. Relief naturally followed the removal of the positive intra-thoracic pressure, but the bronchial fistula in the lung allowed of the development of a pneumothorax of such severity as to jeopardise life by its intra-thoracic pressure on the mediastinal contents.

Harley-street, W.

A CONTRIBUTION TOWARDS THE DISCUSSION ON THE EMPLOYMENT OF ALCOHOL IN MEDICINE.[1]

BY A. G. BARTLEY, M.D., M.R.C.S.

MY opinion is adverse to the use of alcohol, and I might proceed to give grounds for this opinion; statistics, quotations from authorities, as well as facts, I might supply myself, so as to make my paper more or less exhaustive. My aim is, however, less ambitious. I have called my paper a contribution merely. It is, in short, an account of certain incidents in my experience which bear upon the question; and these I relate as briefly as possible and in the order of their occurrence. I will begin by relating an incident which first directed my attention to this subject, and which will show that I had taken up a strong ground in this controversy even before I was aware there was such a controversy at all.

After I took my degree in medicine I passed at once into the army, and my first cases of independent medical practice were in a battery of artillery in the Punjab. After a year or so with this corps I served two years in an infantry regiment without a senior surgeon, all this time acting to the best of my lights, but entirely independent and uncontrolled. At the end of this period, and about my fifth year of service, a senior surgeon joined the regiment with power of superintendence. He was an able and a kind man, and it was not at all in a spirit of unfriendliness that, going into dinner one night, he said to me, "I was in your ward this afternoon and found a bad case of delirium tremens in which you had omitted to order stimulants; however, I have made it all right." I replied, "I have no case of delirium tremens at present." He said, "Yes, a bad case, which will probably not survive, and so you had better take care." After some consideration I at length made out the case he referred to, and replied, "That man has no delirium tremens and will certainly be at duty in a week." We thus had a difference of opinion. I begged him, however, to leave the case in my hands, which he did, and the man was at duty in fair health in a week. It was, in fact, a discovery to him, an old soldier, that delirium tremens could be treated successfully without stimulants; and, I must add, it was a discovery to me that, although I knew there was such a disease in the regiment, I had actually treated cases of the ailment myself without knowing it. That delirium tremens can be, and ought to be, treated without stimulants is now a commonplace of practice. I speak of the year 1866. At that time the treatment consisted chiefly in administration of stimulants and opium, and I take no great credit to myself for breaking away from the traditions of the profession. I simply did not treat the disease by name. It would now be called "alcoholic poisoning." I looked on recovery as a matter of course, recorded the case as debility, sometimes from drunkenness, but more generally omitted the remark as likely to draw down the attention of the commanding officer to the offender. On the occurrence of the above incident, however, my attention was directed to the subject. I continued my treatment. My two colleagues continued theirs, and, although we were seldom without a case of delirium tremens, no case of any severity occurred among my patients. I need not say that the matter was often warmly debated. In those days Aitken's Practice of Physic was, as it still is, the chief authority in the medical service, and it was with keen delight that in the new edition of that year I found the treatment of this disease laid down: that, as it proceeded from an irritation of the nervous system by alcohol, the first condition of cure was to remove the cause, to forbid alcohol, and to give food in all possible ways, as the patients were dying of starvation—in fact, the treatment I had been pursuing. Aided by this book, I had the pleasure of making a convert of my senior.

The next three years are barren of incident. I served in the Channel Islands the greater part of the time with a battery about one hundred strong, and quite isolated. After this I returned to India, and was put in medical charge of the Artillery Division at Mooltan. It was in this station that I studied the heat fever, in which I was led to adopt a modification of treatment, which included, I may add, an avoidance of alcohol. I early made observation of another troublesome and prevalent Indian ailment—diarrhœa. Patients admitted to hospital with diarrhœa very rapidly recovered by dietetic means alone, and without drugs. The climate of the Punjab is dry, very different from that of Bengal, where, we know, diarrhœa does not always tend to cure itself. In truth, the diarrhœa was curative, proceeding from some improper ingesta, very frequently a symptom of alcoholic poisoning. On coming to hospital, milk and arrowroot were given as diet, and, with rest and quiet, in a day or two the man was well. Similarly among the children diarrhœa, which was in any case rare, proceeded from something unwholesome they had eaten, or from fever. That arising from the former cause cured itself, and fevers in the hospital, cooled artificially, quiet, and darkened, seldom lasted over the second day. So that a child brought to hospital almost insensible with vomiting and diarrhœa would be quite lively next day, and without any special treatment other than cold applications. Thus, in addition to delirium tremens, which was very rare, two other important Indian diseases, diarrhœa and heat fever, were treated by sanitary measures, any drugs employed being mere adjuncts, and alcohol would only have marred the cure.

There were many cases of acute chest disease in the cold weather. On admission to hospital, they had plainly one thing in common with those suffering from alcohol; they were exhausted from sheer want of food. It was the first and main point of my treatment that this should be met by prompt feeding, most generally by repeated cupfuls of arrowroot and milk. I gave nitre or other neutral alkaline salt, and morphia for hacking cough. The tongue began to clean at once and the temperature to fall, and the haggard and worn patient got refreshing sleep and began to convalesce. In fact, the cases ran parallel with the former ailments I have mentioned, and I soon ceased to employ with them any form of alcohol. They usually passed through a crisis, sometimes extremely severe. The temperature became subnormal—at least, as evidenced by the thermometer; the face shrunken, with feeble pulse. My practice was, at first, to give hot wine-and-water in this stage. However, I found that the stage was very transitory, and that hot milk-and-water was quite as restorative; the patient soon went to sleep, and normal warmth returned.

Hepatic disease is not so frequent in the Punjab as it is found down country, nor by any means so severe. I cannot recollect any deaths due to it directly during my stay, or any case of hepatic abscess. Minor congestions and enlargements were a frequent cause of sickness and invaliding. The treatment a few years earlier consisted in blistering, stimulants, and a mercurial course. Some time in 1863 a surgeon in Burma, whose name I cannot now recall, recommended ammonium chloride. This I tried, and thought it acted very favourably. About 1866 an immense change for the better was brought about by the introduction of podophyllin. It was called the vegetable mercury, having quite supplanted that metal, which indeed became on all hands, in all diseases, quite decried. At the time I now refer to (1870) I began to discontinue the use of podophyllin in hepatic disease, finding Epsom salts far more active and rapid in effects. I remember getting the idea from a translation in the Sydenham Society series of some German researches on the effect of certain saline springs, and made for myself an artificial mineral

[1] A paper read before the Æsculapian Medical Society.

Digitized by Google

water. This, the equivalent of the present white mixture, eased the pain and reduced the size of the liver, just as we are now familiar with, but which was then to me a real discovery. After a few days of this treatment the patients were very much the same as convalescents from chest disease. They needed time and rest and suitable food—in short, nursing,—and had a chance of regaining health. Hepatic disease is, however, ineradicable. It soon recurs in the great heat of the climate and in men not very abstemious, and few once ailing with it serve long in hot climates.

Thus in one after the other of these important diseases experience was altogether against the employment of alcohol. It must be borne in mind that I began with no theory. I gave alcohol in pneumonia and hepatitis, while rigidly withholding it in fever and diarrhœa. I delayed the alcohol, however, in those diseases to a later stage, until the temperature was nearly normal, and at length discontinued it altogether, finding that it retarded the cure and prolonged convalescence. I lost some cases of course, and among others one from delirium tremens, an old soldier who had frequently suffered before, and it was at first a matter of great pain to me to think that if I had followed the usual routine of treatment the cases might have ended differently. My colleagues, I knew, would probably have held so. However, my confidence revived in watching their practice. I had not the mortality or the severity of forms of disease in hospitals around me. I have seen two waiting men attending on delirious cases, holding the patients in their beds, and preventing their injuring themselves, just as I had seen in the old regiment typical cases of delirium tremens; but I had no such cases, and I had no doubt then, nor have I now, that the delirium arose from the free use of stimulants combined with want of food.

After the regimental system had been abolished I found myself superseded in charge of the corps of artillery with which I had served four years, and was attached to a regiment of infantry. The surgeon-major in charge went on leave soon after I joined, and as I was the next senior, according to the new regulations I assumed charge, although quite a new comer. It was then for the first time I became aware how much I had diverged from the ordinary practice—at least, as it was then in the service. The surgeon of the regiment next in rank to myself soon after I joined consulted me about a bad case of hepatitis, with high fever, foul tongue, and diarrhœa. He had given a variety of drugs which I do not remember. I found, however, that he was giving large quantities of food: jugged hare, strong soups, and six or eight ounces of port wine daily. I said I thought the man was getting too much food to digest, recommended milk diet, to stop the wine, and give salines. He replied, to my astonishment, in a nervous way, he would ask —— his opinion. Now this man he mentioned was only a short time in the country. He was ten years my junior, and six or seven years his junior. I said no more, and went about my business. A few days afterwards, however, the matter cropped up again, and he spoke with an astonishing degree of bitterness on the subject. He said he had once before met a man with these views, and he proceeded to refer to a case of mine which he had visited for me on the previous day as likely to die of hectic from want of support. I pointed out to him reasons why the ailment was not hectic, and assured him the man was not in danger. In truth, my case was severe Peshawur fever which resisted quinine, and the diagnosis was doubtful, as the man had originally come to hospital for treatment of a stricture. And, I may add, the man did not die. I saw him often years afterwards at Woolwich. I was greatly surprised at the degree of irritation this surgeon displayed, and became aware that the administration or withholding of alcohol was not merely a scientific question, but one for faith and belief, with strong feeling attached thereto. His case of hepatic disease died; so did at least one other in the two months I had charge of the regiment. My colleague did not again seek my advice in his difficulties, and he was clearly not converted, for, I regret to say, he died himself from the disease in the following hot weather.

A few months after my transfer to this regiment I came home in a troopship, and there again my divergence of treatment left me utterly isolated. I was third in order of seniority on board, and was put in medical charge of the women and children. It was the last troopship of the season, and carried only invalids and soldiers' families. Of the latter there were about seventy, with an average of perhaps two children in each. On the day after leaving Bombay a case of measles was found on board. I took the case into hospital, and every precaution to isolate it was adopted—unavailing, however. The sixth day afterwards six cases were reported. After another six days thirty more were found infected, and put under treatment; and I think that every child on board passed through the disease. The only number I can now recollect is that, after discharging all convalescents, thirty-six cases were sent to Haslar Hospital on arrival at Portsmouth. There must have been from eighty to one hundred cases in all. All these I treated myself in the hospital, restricting myself to this duty at first with the idea of isolation, afterwards in order to control the treatment, for which I was personally responsible. I gave no stimulants, and met every case of high temperature promptly by wet towels to the chest and abdomen, and by giving for food very dilute Swiss milk *ad libitum*. This treatment met with deep disapproval on the part of the mothers, who were all strangers to me, and accustomed to very different treatment. Towards the end of the voyage I found the women were not unsupported in their disapproval. They carried their complaints to the various officers commanding detachments, and thus officially to my senior, the surgeon-major in charge. Now this surgeon-major had been unlucky. He had treated only two children on board, one of them his own son. They were both dead, whereas I had lost no cases, and so, although there was a difference of opinion between us, I had not much difficulty in arranging that the treatment should be left entirely in my hands. I will summarise the result. I was the only medical officer on board who gave no alcohol. I treated personally the largest number of cases, and I alone lost no patients. Moreover, of three children who died on board, two, as I have said, were treated by the senior medical officer, and the third by my assistant. I will give particulars of this, as it is a most illustrative case. It was not a case of measles, and was treated by him in the women's quarters, and I first heard of it when he told me the child was dying. I asked him to let me try to save it, which he gladly did. I put it in hospital with my measles cases. I stopped the wine, very much to its mother's disgust, stayed with it almost an hour, feeding it with milk-and-water, which it took greedily, and left it fully assured it was out of danger. The child lived for a week, and was slowly improving. I gave it no drugs, as it had no symptoms. At the end of this time I told my assistant, whose patient it had nominally remained, to take it again to the quarters, as the hospital had become so crowded. He did so, and, notwithstanding all he had seen of my practice, he put the child at once on brandy, and it died in a few hours. I will make no further comment on these occurrences except to say that perhaps a more crucial experiment could not be devised.

I reached Portsmouth in April, and expected to find the alcohol question a matter of keen debate in England. I need not say I was in this disappointed. I found matters running in the old groove. This is several years ago. We know matters are now righting themselves. To continue. During three years' tour of duty at home I avoided discussion, and, as far as possible, all consultations. I have, however, one instructive instance to bring forward from that period. In the family of a sergeant of the commissariat two well-grown lads, the eldest about ten years old, had caught measles and were very ailing. The mother frequently suggested that the boys should have stimulants, which I refrained from. Now it happened that this sergeant was married without leave, and his wife and family were not recognised. My attendance on them was therefore voluntary; not only so, but her acceptance of my attendance was voluntary, and I found before many days that the children were taking stimulants under the direction of some private practitioner, and I ceased attending. The father, however, was displeased at this, and in a day or two begged of me to call. I did so, and found a great change for the worse, in the eldest especially. To me the cause was patent; besides that, the room smelt strongly of brandy. I did not mention this, but said to the mother as kindly as I could that the boy had no more chance of dying than she or I had if she would follow my directions. She was obdurate, however, and I did not call again. In a day or two afterwards the father came and told me the boy had died. This is the last instance I will bring forward from my military service.

I may mention a case which occurred since my coming to North London, a case of unusually large pleuritic effusion.

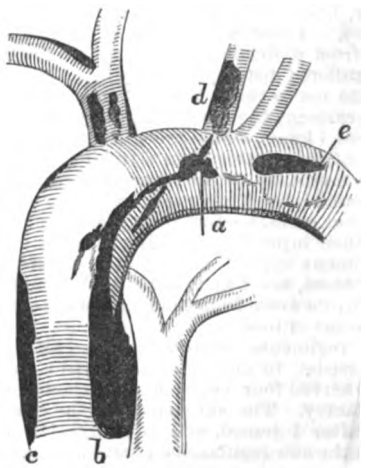
Digitized by Google

In consultation with a physician, specialist in chest disease, the fluid was evacuated, and the patient made a rapid recovery. This physician some time afterwards remarked to me what an excellent case it was—what a remarkably rapid convalescence. I did not emphasise in my reply, as you may suppose, that which it is my duty now to do, that I had carefully omitted the six ounces of port wine daily he had prescribed for my patient. I did once succeed in converting a hospital physician to my views—a *rara avis in terris*. I one day undertook to stand in the middle of his largest ward, and from that position to point out every patient therein who had been taking stimulants for three or four days at least, and I succeeded. To me the paleworn aspect of the patient is unmistakable.

With this I end my paper. It is not for me to go into statistics on the point, such as may be found, I dare say, in books or hospital reports. I know that such statistics are scant, for the question has not yet become a matter of calm scientific investigation. It is still one of the "fads" of the day, which the practical physician has not time to trouble about. Nevertheless, the reform is irresistibly advancing. No one can overlook the unmistakable diminution of the consumption of alcoholic liquors in hospitals. This is probably due in great measure to the greater temperance of the general community—a change of fashion rather than a reform of practice. It has been said long ago that the evils wrought by a theory have never in history discredited the theory; and certainly this would seem to be true in the practice of medicine. The melancholy history of the use of calomel and of opium in India is a saddening illustration. A few men here and there question the theory, and gain adherents chiefly among the young. The older men are not so much converted. They die out, and by-and-by the world awakes and exclaims how foolish the last generation was.

Stoke Newington.

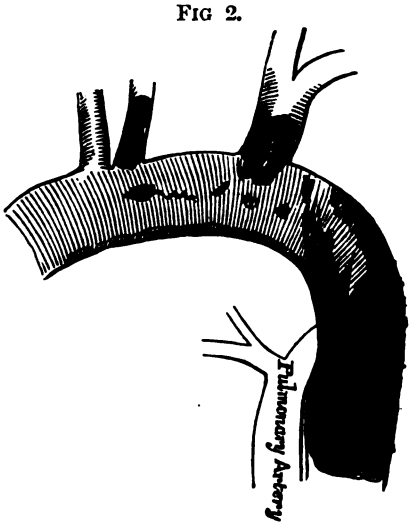
DISSECTING ANEURYSM OF THE TRANSVERSE AORTA RUPTURING INTO THE PERICARDIUM.



BY F. W. JOLLYE, M.R.C.S., L.R.C.P. LOND.

THE following case may be of interest, as showing that a dissecting aneurysm commencing in a part of the arch of the aorta beyond the pericardial sac may nevertheless travel backwards and burst into it, causing death.

J. P——, an old man of seventy-six, who was suffering from senile decay, with occasional attacks of bronchitis, but with no symptoms of cardiac mischief, was in his usual health until getting up about 8 A.M. on Feb. 13th, 1889, when he felt a sudden præcordial pain and was a little giddy. These symptoms passed off, and he felt as usual until about 9 A.M., just after drinking some tea, when he again complained of epigastric pain and faintness. He was held in the chair by two persons until I saw him, about twenty minutes afterwards, when he was collapsed, his pulse very feeble and irregular, hands cold and livid, and quite unconscious. He was immediately laid on the floor, hot-water bottles applied to his feet, and brandy administered in small doses gradually for twenty minutes, when consciousness returned. His heart sounds, on auscultation, were irregular, feeble, and muffled. I left strict orders that he was on no account to be allowed to move his head off the floor or to go upstairs (as he was constantly asking to do), and he obeyed these instructions until 2 P.M. (nearly five hours afterwards), when he suddenly sat up and said he would go upstairs, but immediately fell back dead.



Necropsy.—Abdominal cavity natural. On opening the thorax, an immensely distended pericardium, triangular in shape, apex upwards, presented itself. On opening the pericardial sac, I should say about from half to three-quarters of a pint of blood-stained serum escaped, and a blood-clot covering the right auricle and ventricle, and extending round to the right and behind, was removed, and found to weigh ¾ lb. On looking at the heart and vessels from the front, there was seen to be a blood-clot under the outer coat of the aorta at the base, especially marked between the aorta and pulmonary artery, and from this a clot extended up to the base of the internal carotid and for an inch up its wall. There was also a small clot under the outer coat of the innominate and the third part of the arch. Looking from behind, the external coat of the arch was found ruptured close to its base, and blood-clot extended from the rupture upwards under the external coat nearly to the origin of the innominate. On opening the outer coat and washing away the blood-clot, no rupture of the inner wall could be found near the base; but, on splitting up the arch, a small clot was found protruding from a rupture of the internal coat, about three-quarters of an inch long, and lying obliquely on the anterior wall just below the origin of the internal carotid. This rupture was situated in a raised, calcareous, yellowish plaque; just beyond this there was another small stillate rupture in a similar calcareous patch. The whole arch was much dilated, and the inner surface was mottled with yellowish patches of various sizes, raised above the surface, some being calcified, others still soft. (See Figs. 1 and 2.)

FIG. 1.

Anterior view of the arch of the aorta, showing the staining by blood-clot between the external and middle(?) coats of the vessels. *a* Corresponds to the external coat seated over the rupture of the middle and internal(?) ones (the external coat is not ruptured here). The track the blood has taken can be traced downwards to the base of the aorta (*c b*); the blood-clot does not surround the whole of the anterior half. There are also effusions of blood staining the first inch of the internal carotid, slightly the innominate, and a few stains beyond the subclavian (*e*). The greatest collection of blood-clot in front was between the pulmonary artery and the aorta (*b*). (Reduced ½ diameter.)

FIG 2.

Posterior view of the arch of the aorta, showing the blood-clot surrounding the posterior half of the base of the aorta for about an inch, and also the internal carotid artery and a few other scattered clots. The external coat ruptured over the lower part of this blood-clot on the posterior surface, allowing the blood, to the amount of a pint, to collect in the pericardium. (Reduced ½ diameter.)

Remarks.—I think there can be little doubt that the internal coat gave way whilst getting up, and that the

Digitized by Google

blood gradually dissected its way down to the base of the aorta under the external coat, and that under the increased pressure caused by the drinking of hot tea this coat gave way at its weakest spot—viz., near the base. In this case the dissecting aneurysm did not start from an atheromatous ulcer, as it may do in some cases, but from an erosion of the intima by the sharp edges of the calcareous lamellæ, which are brought to bear on this coat by the contraction of the atheromatous patch, due to the loss of some of its softened-down constituents. The primary lesion, as is usual, was in the anterior wall of the arch. According to Dr. Hayden,[1] a dissecting aneurysm of the first part of the arch usually bursts into the pericardium; but, on the contrary, when the second part of the arch or any point of the aorta beyond this point is the seat of the primary lesion, separation of the coats is usually found to extend along the remainder of the length of the vessel and over the whole or greater part of its circumference, whilst the blood has re-entered through an opening in one or both common iliac arteries. Dr. Duffin has kindly referred me to some similar cases published in the Pathological Transactions, but these I have not at hand to refer to.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

SUPPRESSION OF URINE FOR NINE DAYS AFTER PARTURITION; DEATH.

By F. F. BOND, M.D.

I WAS called to see Mrs. H——, aged twenty-seven, on Jan. 9th, at 2 P.M., and was informed that she had been delivered of a stillborn child at 5 A.M. the same morning, being attended by a midwife. She had advanced to seven months. It was her third pregnancy: the first had been normal, and the child living; the second was only seven months, and the child dead. The woman was subject to epileptic attacks, and had a very nervous temperament. The confinement had been very speedy, and was followed by rather severe flooding, which, however, soon abated. I found her suffering from very intense "after-pain," otherwise her condition was good. For the pain I prescribed a mixture of bicarbonate of soda and opium. The progress of the case was as follows:—Jan. 10th: Pain better; some vomiting; very little lochia. Pulse 82; temperature normal. Passed no urine. I sent a simple effervescing mixture, with instructions to let me know at night if no urine had been passed.—11th, morning: The patient had passed no urine. She had not sent because there had been no uneasiness. Pain and vomiting ceased; temperature and pulse normal; tongue clean. Passed catheter, but found only a few drops of urine in the bladder. Evening: Very intense pain over the loins; very little lochia (not offensive); per vaginam no tenderness or resistance to be felt. Again passed catheter; still no urine. Breasts rather full. Ordered hot fomentations to the loins and vulva, a strong calomel and jalap purge, a morphia and belladonna suppository, and an effervescing diuretic.—12th, morning: Has passed no urine; only one free stool. Pain over loins very intense; brown fur on tongue, rather dry; pulse 90, and temperature normal; restless; very little lochia. Passed cathether; still no urine. Ordered Simpson's bath; also to take ten minims of antimonial wine and thirty minims of tincture of jaborandi in effervescing draught every three hours. Evening: Much easier; perspiring profusely; no urine; a vesicular rash over the body.—13th: Pain over loins, but not very severe; passed fair nights; easy; no urine; one stool; tongue clean; pulse 80, and temperature normal; rash drying up; will take very little food or medicine. Ordered another Simpson's bath.—14th: Much the same as yesterday.—15th: Not so well; vomiting and retching; very restless; pulse and temperature as before; bath had acted well; tongue lightly coated with brown fur. Ordered a simple effervescent mixture, also counter-irritants to the epigastrium and loins, and to repeat the bath.—16th and 17th: Much the same; declines both food and medicine; very restless; still no urine; pain over loins continued, but not very severe. The bath was employed each day, which acted fairly well.—18th, 9 A.M.: Much worse; pulse 84; tension much increased; temperature normal; vomiting and retching; very drowsy; delirious occasionally; breath smells of urine for first time; sordes on lips and gums. She gradually became worse, convulsions set in at 2 P.M., and she died about 6 P.M.

Unfortunately very little could be done in this case; the patient would not take medicine, and only very little food. The Simpson's bath had acted very well indeed, and probably kept the patient from succumbing earlier than she did. The cause of the suppression of urine is very obscure; I am rather inclined to believe it was the result of impacted calculus in both ureters, though there was no history of any previous attack of the kind. If it were so, it must be very rare, and rarer still its coincidence with parturition. Unfortunately a necropsy was not allowed.

REMARKABLE ACTION OF ANTIPYRIN IN RENAL DISEASE.

By M. H. FEENY, M.R.C.S., L.R.C.P.E., L.M.

I REGRET that absence in continental travelling has compelled me to hold back, through so many months, the report of a case so striking and important as the following. It came under my care in the summer of last year, while acting as honorary medical officer to the Cottage Hospital at Clevedon, Somerset. On the card over the patient's bed was written "J—— B——, aged twenty-nine; Bright's disease." The matron informed me that the case was regarded as hopeless. The patient was admitted on March 3rd, 1888, with the following history. Her father, having enjoyed good health till a few days before his death, died of inflammation of the lungs at the age of sixty-eight. Her mother died at the age of sixty-six from chronic rheumatism and liver disease. She had had seventeen children, of whom five died in infancy, but the remainder grew up strong and healthy. The patient had been in good health till two months previously. She was then seized with a diphtheritic sore throat, and was soon after ordered to Clevedon for change of air. On the journey she caught cold, dropsy quickly supervened, and she was admitted into the hospital on March 3rd. From this date till the following June the case was carefully nursed, and the routine *rôle* of medication was adopted. Still the malady made steady progress, and on June 14th, when I saw her for the first time, I observed the following condition. There was extreme general dropsy—the abdomen, face, and extremities distended with dropsical effusion; great pain in the back, especially the lumbar region; intense headache; failing vision; heart action weak and irregular; difficulty of breathing, owing probably to a pushed-up diaphragm and pleural effusion; skin sallow, tense, and shining; urine scanty, of high specific gravity, and loaded with albumen; anæmia and general prostration. The condition of the eyes was very characteristic, the lower lids forming two distended translucent pouches. But the state of the ocular conjunctivæ was very striking. These were, to a large extent, raised from the sclerotic in transparent bladders of effusion, producing the condition called chemosis, and seriously endangering the circulation of the cornea. For some days I saw the case each morning, as a matter of form, as I passed through the wards. She took little notice of what passed, having evidently abandoned herself to despair. From previous slight but inconclusive evidence of antipyrin in renal cases, and with a view to relieve the distressing headache, I decided on the use of the drug. I ordered three grains twice a day, with strict injunctions to observe carefully the action of the heart. The need for this precaution was quickly demonstrated by increased irregularity, fainting, &c. On the third day the dose was reduced to three grains daily. From this date general amelioration of the symptoms was observed, and constant steady progress reported. After a few days a tonic supplemented this treatment, and in the course of three weeks a great change was observable; the dropsy was much less, the intense headache

Digitized by Google

relieved, the appetite improved, and the patient much brighter and more hopeful. By the beginning of August she was up and about, visiting her friends. All traces of dropsy had disappeared, the general health was good, and there remained only a small quantity of albumen in the urine. On Aug. 13th she was discharged for a convalescent home. This was a very striking case, and it attracted much local attention.

Just a word about another case of a different type. While spending some of the winter months at Arcachon, a clergyman, aged sixty-four, consulted me. He had been in failing health for some time, and his French physician was treating him for diabetes. I found a large quantity of sugar in the urine. I again decided on the antipyrin treatment, and, strange to say, the same cardiac intolerance manifested itself. I reduced the dose to three grains daily. At the end of three weeks the patient's health was much improved, and the quantity of sugar reduced to one-fourth. Hurried away in my travels to the Riviera and Italy, I lost sight of the case. It afforded, however, another strong link to the chain of evidence in favour of antipyrin in renal disease.

Leinster-square, W.

SUCCESSFUL TREATMENT OF A CASE OF DYSENTERY BY STRONG ENEMATA OF ALUM.

BY JOHN HEPBURN, L.R.C.P., L.R.C.S., L.S.A. LOND.

IN the following case the above treatment proved so eminently successful that I have thought it worthy of publication.

On June 4th I was called in to see J. G——, aged twenty-seven, female, whom I found was suffering from a severe and well-marked attack of dysentery. The patient stated that she had that day returned from the country, where she was in service; her illness had lasted six weeks, during which time she was under the treatment of local medical men; but as her condition was gradually becoming worse, she had been advised by them to return to her home. She complained of violent purging (about twelve stools in the twenty-four hours), accompanied by pain and tenesmus, the stools being liquid, very offensive, and bloody; she also suffered from constant nausea and vomiting. Lead, opium, bismuth, ipecacuanha, Dover's powder, and many other astringents were tried in various combinations, but with very little success. On June 10th, as she was no better but gradually becoming weaker, I thought it advisable to try some other plan of treatment. Accordingly I ordered her two enemata daily, each containing half an ounce of alum to the half-pint of water. The first injection brought away a good deal of "dirty stuff," presumably shreds of tissue and sloughs, and caused a certain amount of smarting pain; this, however, subsided after a short interval, the patient reporting that she felt much more comfortable; her condition then began immediately to improve, the tenesmus becoming less, the stools not so frequent and more solid, and the sickness ceasing. The second injection caused less pain, and the improvement continued. The same treatment was followed on the next day (June 11th). She was now so very much better (the stools being only three in number in the twenty-four hours, with only streaks of blood) that on the ensuing day the enemata were omitted; but on the 13th she relapsed, the stools becoming more frequent. I then thought it advisable to resume the injections; accordingly two were administered on the 14th, the same good results following them as on the former occasion. This treatment was continued till the 17th, the patient improving day by day. From the 17th till the 21st one injection a day was found sufficient, and, finally, on the latter date they were left off altogether, the patient having made a perfect and uninterrupted recovery from the 14th.

That the favourable termination of the case was entirely due to the enemata I think is sufficiently proven: first, by the good result obtained from the first two injections and rapid relapse on leaving them off on June 12th and 13th; secondly, by the absolute recovery of the patient in seven days after an illness lasting over eight weeks, during seven of which purging, with tenesmus and bloody stools, nausea, and vomiting had existed in varying degrees of severity.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

ST. MARY'S HOSPITAL.

TWO CASES OF NEPHRO-LITHOTOMY; RECOVERY; REMARKS.

(Under the care of Mr. PEPPER.)

IT is only during the last ten years that the operation of which the cases given below are examples has been performed, and calculi removed from a kidney when the symptoms of stone in it are subjective, and there is no evidence of abscess or fistula in the loin. During that time, however, our knowledge of the surgical treatment of renal diseases has advanced rapidly, and many patients formerly condemned as incurable have been restored to health. In the first of Mr. Pepper's cases there was no hæmaturia, to the absence of which he draws attention in his remarks. Although not a constant symptom, it is an important one in the diagnosis of renal calculus. Wright[1] says: "My own conclusion is that renal hæmaturia is the only single symptom of anything like cardinal importance, and that this, if the trouble is of more than a year's standing, and there is no evidence of nephritis, and there is no tumour to be felt, makes the diagnosis of calculus fairly certain." It will be also noted that the stone was not easily felt on exposure of the kidney, and that, although the opening through which it was extracted was made in the anterior part of the pelvis of the kidney, and not through the renal substance, there was considerable hæmorrhage. Jacobson[2] recommends the choice of this part of the kidney for the incision; he continues his remarks on the subject of hæmorrhage at the operation as follows: "Another and, I think, a preferable method of exploring in doubtful cases is to open the pelvis or the thinner kidney tissue close by, and to pass a finger into the organ," &c. The arrest of the hæmorrhage is usually accomplished by the means employed by Mr. Pepper, but has required plugging of the renal incision.

CASE 1.—Walter G——, aged twenty, a note-paper folder, was admitted into St. Mary's Hospital on Feb. 24th, 1888, for pain in the left side. He first commenced to have pain in this region four or five years ago. The pain was paroxysmal in character, and at first he used to have an attack about every three months. The attacks increased in frequency and strength, and a year ago he noticed the pain radiating to the left thigh and testicle. Shortly before admission the attacks had been of almost daily occurrence, each lasting about an hour. They were often brought on by carrying a heavy weight or running. At times there was a thick, light-brown sediment in the urine, which clung to the vessel. The pain when most severe was accompanied by violent attacks of vomiting. There was not known to have been hæmaturia at any time.

From the date of admission to Feb. 28th he was kept in bed, and during that time had one attack of pain. The urine was faintly acid in reaction, sp. gr. 1020, with a trace of albumen and slight deposit of urates, but contained no blood.

On Feb. 28th he was placed under ether and turned on his right side, with a large pad underneath him to render the left lumbar region prominent. An incision about five inches in length was then made, beginning just below the tip of the twelfth rib and extending backwards and slightly upwards towards the transverse process of the first lumbar vertebra. The different layers of the abdominal wall were then divided and the perinephritic fat exposed. The abdominal wall in front was pressed forcibly inwards to raise the kidney nearer to the surface of the wound. The perinephritic fat was next torn through, and the kidney, and with it the descending colon, exposed. The kidney was

[1] Med. Chronicle, vol. v., p. 462. [2] Operative Surgery.

Digitized by Google

found to be very movable, and was explored with the fingers both in front and behind. No stone was detected, but the pelvis of the kidney was found to be dilated. The kidney was again manipulated with the fingers, and at last a hard nodule was made out at the upper end. This was the stone firmly fixed in one of the calyces. An opening was then made with the finger-nail through the pelvis in front and the finger introduced. Many ineffectual attempts were made to remove the stone with numerous forceps, but it remained firmly embedded. At last it was removed with the fingers and a director, the difficulty in its extraction being partly due to the close proximity of the last rib to the iliac crest. There was considerable hæmorrhage from the kidney substance, which was checked by pressure with hot sponges. The wound was irrigated with perchloride of mercury solution (1 in 2000), drainage-tubes inserted in front and behind the kidney, and the edges of the wound drawn together with silver sutures. Iodoform and wood-wool pads were used as dressing. The patient stood the anæsthetic well. The calculus was composed of uric acid. It weighed 70 grains, was oval in shape, measured 1 in. by 3 in., and was covered on the surface with splendid crystalline spicules.

After the operation the patient rapidly recovered. For the first few days there was blood and albumen in the urine, but this soon passed off. On April 1st the wound was nearly healed and the patient was allowed to get up; on the 5th the wound was quite healed; and on the 16th he left the hospital quite well. The temperature never rose above 99·4°. The patient was quite well twelve months after the operation.

CASE 2.—C. W——, aged thirty-four, a factory manager, was admitted on July 14th, 1889, into St. Mary's Hospital, under the care of Dr. Broadbent, for symptoms of renal calculus. The family history was good. The patient was unmarried, and, with the exception of rheumatic fever a year previously, had had no serious illness. He had lived a healthy life, and a few years ago went in extensively for athletics, but at last broke down whilst in training. Five years ago he was passed as a good life by an insurance company. The patient had suffered from attacks of pain in the left lumbar region ever since he was a boy. An attack would come on suddenly every two or three months, and in the intervals he would be quite well. A long walk would often bring on the pain. He never experienced pain in other parts than the left loin. He never noticed any blood in the urine, but his mother told him that he used to have attacks of pain when a child, and that then there was hæmaturia. Since last November, three months after he had rheumatic fever, the attacks of pain had become more frequent and severe, and had remained so. The last and most violent was on July 13th, 1889, and continued from 11 A.M. to 8 P.M., leaving him prostrated. He had noticed that he was free from pain whilst lying down.

On admission he was well nourished, but with an anxious expression. There appeared to be a slight fulness in the left lumbar region, which was tender on pressure. There was no undue frequency or difficulty in micturition. The urine was acid, sp. gr. 1020, and contained blood, pus, and one-fourth albumen.

On July 18th the man was placed under chloroform, and Mr. Pepper performed lumbar nephro-lithotomy. The kidney was easily exposed and the stone readily felt. Some difficulty was found in removing the calculus, which filled the pelvis of the kidney, and had one large spur firmly fixed in a calyx. The drainage and dressing were as in the preceding case.

After the operation the patient was troubled with sickness for two days, and on July 22nd he became slightly jaundiced. The urine for the first few days contained a good deal of blood. The drainage-tubes were removed—one on the 16th and the other on the 30th. The temperature was 100° on the 19th and 100·2° on the 20th; since then it had been normal. At the present time (Aug. 12th) the wound has nearly healed, there is no escape of urine from it, and he is practically well. The urine is normal, with the exception of a few pus cells occasionally.

The original calculus was oval, almost black, and with a mulberry-like surface, and was evidently composed of oxalate of lime; it subsequently became much enlarged and irregular in shape, from incrustation with phosphates. In neither case was there any suppuration in the wound.

Remarks by Mr. PEPPER.—In the first case the absence of hæmaturia is remarkable, considering the frequency of the attacks of pain and their violently paroxysmal nature. This seems to show that the pain is caused more by distension of the kidney, owing to the ureteral orifice being temporarily blocked by the calculus, than to the movement of the latter. In the second case it will be noted that the pain did not radiate. It may be further mentioned that in neither case was there any retraction of the testicle. (For the above notes I am indebted to the surgical registrar, Mr. Crowle.)

TOTTENHAM HOSPITAL.

A CASE OF HYDATID CYST OF THE LUNG; DEATH; NECROPSY.

(Under the care of Dr. ADOLPH RASCH.)

HYDATID OF THE LUNG is a disease very uncommon in this country, and the following is a typical example of it, both as regards situation—the lower part of the right lung—and local signs. Fagge[1] says: "Pulmonary hydatids are almost always migrated parasites of the liver. Clinically, hydatid disease of the lung is scarcely likely to be suspected until one or more of the daughter cysts have been expectorated." This applies more especially to those cysts which are deep seated, but, as regards the expectoration of the small cysts and portions of membrane, it must be recollected that it is much more common for a hydatid of the liver to be discharged in this way than for a hydatid having its primary seat in the lung. In either case the expectoration may be similar at first, but when derived from a hepatic cyst it usually becomes bile-stained. Thomas of Adelaide[2] states that he has observed in most cases of hydatid of the lung "an alteration of the percussion note, which becomes markedly tympanitic over a greater or less area around the tumour." In a case of hydatid of the lung recorded by Fagge, where the fatal result was due to hæmoptysis, the blood came from a branch of the pulmonary vein; this had become obstructed and dilated into a cylindrical tube as large as a lead pencil, and had afterwards opened into the cavity that had before lodged the hydatid, although this cavity was shrinking. For the account of the case we are indebted to the house surgeon, Mr. R. Philip Brookes.

T. L——, aged twenty-two, a coalheaver, was admitted into the hospital on Feb. 26th, 1889. He stated that four years ago he had pleurisy on the right side, but that his present illness commenced seven weeks before admission with shooting pain in the right side of his chest and cough. He had lost flesh of late, and had night sweats, but had never brought up any blood.

On admission he was a fairly nourished, muscular man. His lips were blue; he had dyspnœa and spasmodic cough, with copious muco-purulent expectoration. Urine acid; no albumen. Examination of the chest showed the movements on the right side to be diminished, and there was bulging of the intercostal spaces, with absolute dulness over the front and back, the dulness behind extending down to the level of the tenth dorsal vertebra, below which there was a narrow zone of resonance extending outwards, in which moist crepitation could be heard. The breath-sounds and vocal fremitus were absent over the dull area, but a distinct creaking synchronous with the respiratory movement could be heard all over. On the left side of the chest the movements were increased, the breathing was puerile, and there was no dulness over the lung. The apex beat of the heart was in the sixth interspace, in a line with the anterior fold of the axilla; no murmur was audible. The edge of the liver could be felt an inch and a half below the ribs.

During the ten days the patient was in the hospital there was no perceptible change in his condition. His temperature was of a hectic type, varying between about normal in the morning and 101° in the evening. On March 8th he had a sudden attack of hæmoptysis and died.

At the necropsy, on opening the thorax, a large hydatid cyst was seen occupying the right side of the chest, and extending for an inch beyond the sternum to the left. The pleural cavity, with the exception of the diaphragmatic surface, was entirely obliterated by dense fibrous adhesions, which formed the capsule of the cyst. Towards the apex this capsule became gradually thickened to the extent of about an inch, the thickened portion being composed of

[1] Principles and Practice of Medicine, vol. ii., p. 557.
[2] Australasian Medical Gazette, June, 1888. Sajous, vol. i., 1889.

Digitized by Google

compressed lung of an ashy-grey colour and tough consistence. Against the vertebræ another portion of compressed lung was found; while covering the surface of the diaphragm was a layer of lung from half an inch to two inches deep, which was not airless, but contained several small suppurating cavities with ragged edges. It was from one of these cavities that the hæmorrhage had proceeded. The hydatid membrane had not been ruptured and was everywhere in contact with the fibrous capsule, no hæmorrhage having taken place between them. Numerous small apertures existed in the fibrous capsule, which communicated with the large bronchi. There were no daughter cysts. The clear fluid which the cyst contained showed a trace of albumen, and in the sediment hooklets and echinococcus heads were found. The left lung was hyperæmic; no cavities or tubercle. There were no signs of hydatid disease in any other organ.

EDINBURGH ROYAL INFIRMARY.

A CASE OF SUICIDAL PENETRATING WOUND OF THE NECK; TRACHEOTOMY; RECOVERY.

(Under the care of Mr. MILLER.)

THIS case is one of those which, requiring prompt treatment, usually come under the care of those resident in the hospital to which the patient may be admitted. There are so many elements which enter into the consideration of such cases that it is a matter of congratulation when the patient is discharged well after the infliction of a wound which penetrates the air passage. For not only is the wound a serious one as regards danger from hæmorrhage, and the lung complications which are apt to follow its infliction, but the man is usually in a bad state of health, and frequently suffering from chronic alcoholism, delirium tremens, or mental disease. In one of the earlier additions of a text-book on surgery (1870) we read of the treatment of wounds of the neck: "Plasters to the skin are inadmissible, and so are sutures." The treatment adopted in this case proves their utility, and also the advantage of early tracheotomy. There is a difference of opinion as to the advisability of employing sutures in wounds of the neck. Walsham[1] says: "The wound should not, as a rule, unless quite superficial, be approximated by sutures or strapping, but by position." Bryant[2] continues: "But it must be left to the surgeon's judgment to decide when they may be necessary according to the exigencies of the individual case." Keetley[3] writes: "If these sutures will not interfere at all with drainage, use them. In most cases sutures are not necessary." Erichsen[4] recommends a few stitches introduced at the sides, but not in the centre of the wound. Pick[5] says: "Sutures are in ordinary cases unnecessary, for the edges of the wound can be kept tolerably in apposition without them; and, as primary union can hardly be anticipated, there is no motive for sewing the edges together. They are therefore rarely used in such cases." He speaks doubtfully as to their usefulness when the windpipe has been opened, alluding to the "traditional horror" of them in such cases. There is now, however, with our present system of antiseptic treatment of wounds, much less risk of septic inflammation, and, provided escape for any air which may be expelled from the air passage be secured, with ready exit of discharges to the surface, the judicious application of sutures will do much to shorten the duration of treatment and diminish the size of the scar resulting from such injuries. Due attention must always be given to the position of the head, whether sutures be inserted or not, as this is an important aid to the treatment. We are indebted to Mr. Alexander Miles, the resident surgeon, for the account of the case, which was treated by him.

The patient, S. J——, a retired publican, aged thirty-six, was admitted into Ward 6, Royal Infirmary, Edinburgh, on June 19th, 1889, at 10.15 A.M., under the care of Mr. A. G. Miller. About an hour previously to his admission he had attempted to commit suicide by cutting his throat with a large, rather blunt bread-knife. The incision in the skin and superficial fascia measured about five inches from side to side. It was almost transverse, but more of it was on the left than on the right side of the middle line. At the left angle of the wound there were marks as if the knife had been drawn across the skin more than once. Only the anterior jugular vein and some branches of the superior thyroid vessels were injured. On the left side the sterno-hyoid and sterno-thyroid muscles were completely divided, and on the right the anterior belly of the omo-hyoid in addition. The thyro-hyoid membrane was completely severed and an opening made into the pharynx. The patient was seen soon after committing the deed by a surgeon, who introduced a small tracheotomy tube between the vocal cords through the opening in the pharynx, and then sent him to the hospital.

On admission the wound was thoroughly washed out with corrosive sublimate solution (1 to 2000), and all the bleeding points secured. The tube was removed from the larynx and the high operation of tracheotomy performed through an incision carried downwards at right angles to the self-inflicted wound. The opening into the trachea included the cricoid cartilage and the three upper rings. A middle-sized tracheotomy tube was introduced. The wound in the pharynx was then closed by stitching the several edges of the thyro-hyoid membrane and the muscles together with five or six catgut sutures, the margins of the wound being inverted. The superficial wound was brought together by horsehair stitches and a small tube introduced for drainage. The wound was afterwards dressed with wet boracic lint and corrosive wool. The patient was then put into a bronchitis steam tent, and fed by means of a nutrient enema of beef-tea, eggs, and brandy every three hours.

The man was very anxious that his life should not be saved, and threatened to renew the attempt to destroy it if he got an opportunity. He, however, remained very quiet during the day, and did not interfere with his dressings in any way. After the operation the pulse was fairly strong, 100, regular; temperature 98·8°. At night the temperature was 99·4°; pulse 96, still good. His urine had to be drawn off, as he had passed none since he came in.

June 20th.—The temperature remained about 100° all day. Pulse good, 96; respiration normal. The edges of the superficial wound are adherent.

21st.—Patient rather worse to-day. Breathing somewhat rapid and shallow. No cough. No pain in chest. No physical signs of pneumonia to be made out. Pulse weak and rapid, 140. Temperature 97·8° at night. As he could now breathe quite freely by the mouth, the tracheotomy tube was removed and the wound allowed to close up. Superficial wound in neck healed; some of the stitches and the drainage-tube removed. The patient was fed by the nasal tube. A dose of paraldehyde (ninety minims) given to produce sleep had little effect.

22nd (morning).—Patient rather better to-day. Pulse and respiration more satisfactory; temperature 100·2°. In the evening the temperature began to rise and went up to 102·4°; pulse very rapid (148), small and feeble; respiration 20, full and regular. The patient's general condition is worse than it has yet been. An ounce of brandy and five minims of tincture of strophanthus were given every three hours.

23rd.—Patient much improved to-day. Pulse slower, stronger, and fuller. The temperature came steadily down to subnormal. In the evening the patient was fed by the mouth for the first time.

24th and 25th.—Patient steadily improving.

26th.—Wounds in neck entirely healed up. Patient takes his food, and sleeps fairly well, but is still very melancholic and anxious that his life should be ended.

27th.—He was removed to-day to a lunatic asylum.

MORLEY HOUSE CONVALESCENT HOME.—This institution, situated at St. Margaret's Bay, near Dover, was founded for the sole benefit of London workmen, by members of which class it is also managed. It provides thirty-eight beds, four of which are maintained in the wing recently added for postmen by the gift of the salary accruing to Lord Wolverton when Postmaster-General. The Home is supported by collections at London workshops and grants from the Hospital Saturday Fund, in addition to the endowments arising from the gifts of the late Samuel Morley and the generosity of Lord Wolverton. On Saturday last about 400 working men from the metropolis visited the home, and, after inspecting the arrangements made for the comfort of the inmates, participated in various sports provided for their entertainment.

Medical Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Diagnosis and Treatment of Small Submucous Fibro-myomata of the Uterus.

A MEETING of the Obstetrical Section was held on May 24th.

Dr. BAGGOT exhibited a Myoma of the Uterus which had been removed that morning in the Rotunda Hospital by Dr. Macan, the means of removal being supervaginal amputation. Also two Ovarian Tumours, which were removed in the same institution. In the last two cases the patients had made perfect recoveries.

Dr. HORNE exhibited an Ovarian Tumour removed by Dr. Coppinger from a woman in the Mater Misericordiæ Hospital. The patient was about eighteen years of age. About six months ago, while running, she tripped over a stone trough and fell, striking her left side against it. At the time she did not feel much inconvenience, but on the following day she had a good deal of pain in the left lumbar region, and was obliged to go to bed, where she remained three days. She sought no medical advice at that time. At the end of two months she began to suffer from pain immediately under the left ribs, for which she sought medical advice. The doctor who examined her found a tumour lying immediately below the spleen. But what she remarked about the tumour was that when she stood up it fell down; but when she lay down in bed at night it rose up out of the pelvis, immediately under the left ribs. She only had pain at night, which prevented her from sleeping. As there was some doubt whether it was an ovarian tumour or a displaced or cystic kidney, Dr. Coppinger made an incision in the abdomen so as to see the tumour, which was not very much larger than an orange. He first made an incision of about two inches long. The growth was then high up under the left ribs, and he (Dr. Horne) had to press it down to the wound, where it was punctured by Dr. Coppinger, and removed without difficulty. It had a very large pedicle, which had allowed it to move freely over the abdomen.

The President (Dr. W. SMYLY) remarked on the diagnosis and treatment of Small Submucous Fibro-myomata of the Uterus. So long, he said, as the rule was generally accepted that in every case of severe uterine hæmorrhage not connected with existing pregnancy the cervix should be dilated and the cavities explored with the finger, the diagnosis of these tumours presented no difficulty; but since the introduction of the curette had rendered this painful and somewhat dangerous preliminary in the larger number of cases superfluous, it became of much interest to ascertain whether these new growths could be diagnosed without previous dilatation. Four cases were detailed showing that this was the case. The necessity for dilatation was indicated partly by the condition of the cervix and partly by feeling the new growths by sound or curette. In his opinion, dilatation of the cervix uteri was necessary only in order to remove small tumours, polypi, or portions of retained ovum. Large tumours should not be removed per vaginam, and hæmorrhage alone was not an indication. The method of dilatation which he now adopts is to commence with iodoform gauze, and, if necessary, complete the process with Hegar's dilators. The iodoform gauze is easily employed; it may be left *in situ* for three or four days, and is, therefore, especially adapted to the wants of the busy practitioner. In all the cases the tumours were removed by means of Schultze's spoon forceps. With this instrument diseased tissue alone is attacked, and, with ordinary care, no harm can be done; enucleation, on the other hand, is much more dangerous and difficult.—Dr. J. BYRNE said the great difficulty was to dilate the external os, and, after that had been done, there was as great difficulty in dilating the internal os. Iodoform gauze was a great improvement as a gynæcological appliance for the purpose.—Dr. MACSWINEY said the paper had dealt with several points of great importance to the specialist. Dr. Smyly objected, apparently on good grounds, to the practice of frequently dilating the os or cervix, except where he recognised a submucous, fibroid, or other polypus, or where there was ovular membrane, and he wished to know how would Dr. Smyly determine that the hæmorrhage was due to a tumour or some other condition.—Dr. KIDD observed that Dr. Smyly had said that some authorities preferred the knife to Hegar's dilators. In the case of a woman who had not borne children, if the knife were used, the difficulty of the operation would be enhanced by the hæmorrhage. He said one of the advantages of Hegar's dilators was that they did not occasion anything like the amount of hæmorrage that would occur if the cervical canal and os were opened with a knife sufficiently to admit of fingers being introduced into the uterus.—The PRESIDENT, in reply, said that the difficulty there sometimes was of distinguishing between incomplete abortion and the existence of fibroid tumours was one of the things that had induced him to write the present paper. In the fourth of the cases that he had narrated, the woman had been fourteen months married, had had an abortion, and her uterus was large and flabby; and therefore it was natural to suppose that the case was one of incomplete abortion. As to treatment in such cases, if the abortion took place before the fourth month, he would not use the dilator, but would simply scrape and wash out the interior of the uterus, and then inject it with either perchloride of iron or liniment of iodine. If the placenta had formed, the best course was to dilate and remove the placenta with the finger. It was common to split the cervix as far as the vaginal junction; but the division of the internal os with a knife was not very popular. He had no doubt that there would be more hæmorrhage when a knife was used than with a dilator, but he had had no experience of the two cases. Hegar's dilator was an excellent instrument when the os was already somewhat dilated; but if the cervix was rigid, the dilator was very apt to lacerate it, and in such a case it was better to begin with iodoform gauze, which was a very simple thing to use.

Notices of Books.

Die Chirurgische Behandlung von Hirnkrankheiten. Von ERNST VON BERGMANN. Zweite, vermehrte, und umgearbeitete Auflage. Berlin, 1889. Verlag von August Hirschwald.—This is an enlarged and revised edition of an article which originally appeared in von Bergmann's "Arbeiten aus den Chirurgischen Klinik der Königlichen Universität, Berlin." Although only two years have elapsed since this article was first published, considerable additions have been made in this second edition. These consist in additional cases, and also in an enlargement of the scope of the article. The subject is divided into five parts. In the first the Operative Treatment of Encephalocele is discussed. Two good cases of the removal of nasal or sincipital encephaloceles are given, one by von Bergmann and one by Schmitz of St. Petersburg. From these cases and from general pathological and clinical considerations, von Bergmann is strongly of opinion that sincipital encephaloceles ought to be submitted to a radical operation. This section is entirely new. Then follows a valuable article on the Pathology, Symptoms, and Treatment of Cerebral Abscess, which is well up to date, and contains accounts of his own cases and of others recently published in this country, in America, and on the Continent. The third section is devoted to a similar discussion of the Surgical Treatment of Intra-cranial Tumours. Trephining for Epilepsy is the subject of the fourth section, and the fifth and last is a brief article on Puncture of the Lateral Ventricle and Operations for the Diminution of Intra-cranial Pressure. In a case of severe tubercular meningitis marked by coma, slow pulse, Cheyne-Stokes respiration, fixed dilated pupils, and twitchings in one arm, von Bergmann trephined the frontal bone and tapped the lateral ventricle. The immediate effects were excellent; consciousness returned, the pupils reacted to light, the pulse and respiration became more natural, and all went well as long as the cerebro-spinal fluid continued to escape through the puncture. But this drain ceased, the serious symptoms then recurred, and the child died. Although not successful in saving the patient's life, this case was a strikingly encouraging one, and it shows that there is some

Digitized by Google

ground for hoping that tubercular meningitis even may be successfully dealt with by the surgeon. The whole pamphlet is admirably done and well worthy of careful study.

A *Guide to the Use of the Mineral Waters of Buxton.* By W. H. ROBERTSON, M.D. Twenty-third Edition, revised and enlarged. Pp. 65. Buxton: C. F. Wardley. 1889.—*Buxton: its Baths and Climate.* By SAMUEL HYDE. Pp. 134. Manchester and London: John Heywood. 1889.—The fact of Dr. Robertson's Guide having already gone through twenty-two editions, covering an issue of above 30,000 copies, may be taken as satisfactory evidence that it has been found to supply an acknowledged want. It contains full analyses of the waters and all the requisite information as to the means provided for their use, the cautions necessary to avoid injurious results from them, and the general regulations as to diet &c. which should be observed by persons taking a course of them. Dr. Robertson states briefly the diseases in which benefit may be expected, the cases in which the use of the waters is contra-indicated, and the means which should be adopted to fit the system, as far as possible, to derive the fullest benefit from them. It seems a useful guide, but a good index would add to its value.—Mr. Hyde's book seems more intended for the use of the public in general. It consists of two parts, the first giving a description of the locality in which Buxton is situated, its waters, and the several forms of bath in common use; and the second, a description of the town, its neighbourhood, and the excursions which may be made from it. As regards climate, Buxton appears to have a low average temperature, a high annual rainfall (about fifty-one inches); in winter much snow and frost, and no great amount of bright sunshine; but it is free from fog, and has a dry, pure air. Notwithstanding climatic drawbacks, Mr. Hyde is of opinion that it might be advantageously used as a winter health resort in cases of phthisis, instead of Davos-Platz and other Alpine resorts. The information he gives as to the various kinds of baths, and the chapter on "Massage, its Principles and Practice," may be found useful. But invalids and seekers after health should never forget that they are powerful for evil as well as good. "A popular notion prevails very widely that baths can be taken as a rule with impunity, and that it is not necessary to apply to them the usual principles which regulate the use of remedial agents. It must never be forgotten that baths follow the law as to action of all remedies for the relief of disease. They must be both prescribed and dispensed according to certain rules which should regulate the treatment of every case according to its individual merits." Mr. Hyde enumerates some of the diseases in which the waters are found beneficial, but we cannot find any caution as to those in which they may prove injurious. The book has the advantage of a good index.

Beiträge zur Pathologischen Anatomie und zur Allgemeinen Pathologie. Redigirt von Dr. E. ZIEGLER. Band V., Heft 1. Jena: G. Fischer. 1889.—With a new volume the editorship of this excellent publication passes solely into the hands of Professor Ziegler. It fully maintains its previous high quality, as shown by the contents of this first part:—1. C. Nauwerck and W. Barth (Tübingen): Pathological Anatomy of Landry's Paralysis. 2. C. Nauwerck and H. Eyrich (Tübingen): Verrucose Aortitis. 3. L. Caporaso (Modena): Regeneration of the Spinal Marrow of the Tail of the Newt (written in Italian). 4. W. Sachs (Königsberg): New Growths arising from Lymphatics in the Eye. 5. R. Schattenberg (Marburg): A Circumscribed Porencephalic Defect of the Brain in an Adult. 6. D. Fischer (Marburg): Lumbo-dorsal Rhachischisis with Spinal Curvature &c. 7. A. Kirchberg and F. Marchand (Marburg): So-called Fœtal Rickets (Mikromelia Chondromalacia).

Defects in Plumbing and Drainage Work. Described by FRANCIS VACHER. Illustrated; pp. 83. Manchester and London: John Heywood. 1889.—This volume, to a great extent a reprint of papers which have appeared in the *Health Journal*, treats of all questions relating to domestic sanitary fittings, drainage, and water service. It is divided into eight sections, in each of which Mr. Vacher first states the conditions under which the work treated of should be carried out with reference to sanitary considerations, and then gives a number of examples of the manner in which it too often has been, and still is, but never ought to be done. It contains many examples of what the author truly styles "perverted ingenuity," and curious particulars of ill-designed and scamped work. It makes one shudder to think of the risks to health and life people are compelled to run constantly from ignorance, carelessness and cupidity. Mr. Vacher has been careful to point out "what to avoid" in house construction, and, we may add, house-hiring. The book deserves to be studied by householders, medical officers of health, sanitary inspectors, and plumbers. One practical lesson we would deduce from it is: the imperative necessity for a careful skilled inspection of a house before coming under an obligation to rent it. It is difficult to estimate how much sickness and sorrow would be avoided were such a course invariably adopted

Die ersten zehn Jahre der Myringoplastik nebst Angaben verbesserter Methoden zur Heilung von alten Löchern im Trommelfell. Von Professor D. E. BERTHOLD im Königsberg. Berlin, 1889. Verlag von August Hirschwald.—It was in the year 1878 that Dr. Berthold first published an account of his attempts to close old perforations of the tympanum by a plastic operation. At that time he had used the rabbit's cornea for the purpose. Since then he has made two alterations in his method; first he substituted human skin for the rabbit's cornea, and now he uses the thin membrane lining eggs, and subsequently applies outside it spirits of turpentine. In this *brochure* he describes these different methods, refers to the cases published by other surgeons, and finally relates all his own completed cases. It is a method well worthy of the careful attention of aural surgeons, and they will no doubt be glad to have Dr. Berthold's facts thus put at their disposal.

MEDICAL CIVIL SERVANTS AND THE PENSION BILL.

To the Editors of THE LANCET.

SIRS,—The letter of your correspondent "Q" shows the need for a union of medical men holding civil appointments, and as I have been assured that a well-considered plan for such a union would be likely to find favour among those who are chiefly concerned, I should be glad if you would permit me to lay before the readers of THE LANCET the following outline of the proposed objects of such a union, and to state that I shall be glad to receive any suggestions or criticisms from those interested in the matter.

Proposed Association of Medical Civil Servants.

Objects.—1. To unite medical men holding office under the State as medical officers of health, Poor-law medical officers, medical coroners, police surgeons, post-office surgeons, also medical M.P.'s, in a society for mutual assistance. 2. To obtain the establishment of Poor-law dispensaries in towns wherever practicable, and the improvement of the position of medical civil servants generally. 3. To obtain the opening of Poor-law infirmaries and hospitals for purposes of medical study. 4. To advocate the appointment of a Minister of Health. 5. To watch all Bills brought before Parliament affecting the status or duty of medical civil servants.

I am, Sirs, yours faithfully,

H. NELSON HARDY.

Southville Park Villas, Dulwich-grove, S.E., August, 1889.

THE LANCET.

LONDON: SATURDAY, AUGUST 31, 1889.

EVERY fresh contribution to the pathology of malignant new growths is to be welcomed, as enabling us to gain further insight into the manner of their propagation and the best means of dealing with them. It may be long yet before any tangible result can be realised, although it is obvious that the aid given by microscopical investigation has been very considerable. For it is now practically certain that in their origin these formations are emphatically local; that is, that they are the product of a disturbance in the normal cell-nutrition of the particular organ or part where they arise. We have been forced to abandon the notion once so widely held, that the appearance of cancer was the expression of a general, constitutional, or blood state, and must look now to determine what it is in the individual that predisposes the tissues to undergo this remarkable alteration. For, in rejecting "constitutionalism" as the full explanation of the cancerous manifestations, it seems impossible to ignore the existence in many cases of some "predisposition" or defect in growth or nutrition, if the origin of cancer is to be adequately explained. But there is another and most remarkable property possessed by malignant growths, which is special to them, and to which they owe their destructive and fatal character. This is the property of infectiveness within the body, so that parts distant from the primary centre may become the seat of formations similar in kind to those of the original growth. Many have been the hypotheses put forward to explain this "malignancy," some of them highly ingenious and suggestive. The latest endeavour to bring cancer under the prevalent bacteriological doctrines (which seem to have explained so much that has hitherto been obscure in the pathology of infectious disease) has not been successful. It is, however, conceivable that the cancerous cells themselves may be the actual parasites, but how and why they can come to be so transformed from the normal cells of the body are points which are quite inexplicable, and hardly reconcilable with what is known in biological science. The opinion held by Dr. NORMAN MOORE, as expressed in his Bradshawe Lecture, is evidently akin to this. At any rate, he sees in the secondary formations the direct descendants of the primary growth, and happily pointed his remarks on the colonising character of cancer cells by reference to the migrations of human families. We believe, too, that in this he was within the truth; for, in spite of some cases in which long intervals of time have elapsed between the total extirpation of the primary tumour and the appearance of distal visceral growths, the histological characters of such growths, which often far exceed in extent the primary formation, reproduce the features of the latter; and, remarkable as the existence of "latency" is, there is no escape from the conclusion that the two sets of new formations are genetically connected.

The Bradshawe Lecture was based entirely upon the facts in morbid anatomy gleaned by the lecturer from his experience at St. Bartholomew's Hospital. Necessarily, therefore, some of his conclusions respecting the mode of invasion of certain organs, and the proclivity to distal dissemination of certain growths, may be modified by the study of a larger number of instances than he was enabled to cite. But, in the main, especially as regards some varieties—e.g., cancer of the œsophagus and stomach,—his conclusions are, no doubt, concordant with general experience. His observations bear out the general belief that the liver is the organ which is the most frequently infected secondarily, no matter in what region the primary cancer occurs; but it is especially remarkable, as showing how limited such growths are, that in only one of his nine cases of cancer of the colon was this gland involved. The comparative infrequency of the association of calculi with cancer of the gall-bladder and of the kidney is remarkable. But what will most strike the pathologist is, perhaps, the large series of cases of primary cancer of the lung, and of those of the heart and pericardium, which he was enabled to record. Such experience is, we venture to think, wholly exceptional; but it must be remembered that some of the former class were more, strictly speaking, mediastinal than pulmonary in their origin. With respect to nomenclature, Dr. MOORE perfers to deal simply with the two great varieties—carcinoma and sarcoma,—holding that the former include epithelioma, and not apparently regarding the view that carcinoma is a perverted *glandular* growth rather than a mere epithelial one. There is more reason in his discarding the time-honoured subdivisions of scirrhus, medullary, and colloid, which belong, as he pointed out, to the pre-microscopic era of morbid anatomy. The great preponderance of carcinoma over sarcoma in visceral new growths is striking; and it would have been still more obvious had the lecturer been enabled to include uterine cancer in his series. His deductions at the close of the lecture as to the probable duration of malignant growths in various parts of the body were also of interest; but on this head allowance must always be made for the site involved, the local destruction of an organ essential to the maintenance of life leading, of course, to a shorter duration of the disease than when this is implanted in a less vital region. His calculation of the duration of growths, from the period of extirpation of external cancers to the time of death from secondary involvement of viscera, gave an average period of rather more than two years; but in rare cases a far longer immunity even than the fifty-one months (the longest noted by Dr. MOORE) has been observed. The facts adduced in this lecture are capable of ample confirmation, and it would not be difficult for a collective analysis to be made by the co-operation of hospital pathologists based on the lines laid down by Dr. MOORE. For the purpose of accuracy, however, such an inquiry would have to be, as in all his cases, based upon the histological examination of the growths observed. At any rate, the attempt is worth making, in order that our knowledge of the natural history of cancer should be as secure and definite as it is possible to make it.

THE surgery of fractures of the neck of the femur cannot be said to be in a satisfactory state. These injuries are very common, and their results are serious. Not uncommonly life itself is lost, and permanent weakness and

Digitized by Google

lameness are a usual result. The progress noted in other departments of surgery has not reached this, and the want of special interest in the subject has no doubt been due to the difficulties besetting exact diagnosis and really successful treatment. The old classification of all fractures of the neck of the femur into intra-capsular and extra-capsular has been pretty generally given up. It is now recognised that, while such a classification may represent the actual facts in a minority of cases, it is inaccurate in the majority; and, further still, it fails to indicate the important and essential differences met with in these fractures. Instead of concentrating attention on the relation of the fracture to the capsule of the joint, the impaction or non-impaction of the fragments is now laid stress on, and this for an important clinical reason. Impacted fractures, unless becoming unimpacted, are found to unite by bone, and so to be attended with less serious results than the other kind. The great thing to avoid in such a case is any manipulation which can separate the two fragments, and therefore examination of the injured part should always be conducted in such a way that this accident cannot happen. Latterly Dr. SENN of Chicago has been trying to apply this knowledge to cases of unimpacted fractures. He first of all resorted to some experiments on animals. Having made subcutaneous fractures of the neck of the femur within the capsule, he drilled the fragments and fixed them in direct apposition by a steel pin and a bone nail. When this was done firm bony union was obtained. The attempt to apply this treatment to human subjects was felt to be an extreme measure, ill-adapted to the old and feeble patients in whom this accident is generally met; and it has now been shown to be wholly unnecessary, for the same end can be obtained by simpler and milder measures, to which no objection on the score of severity can be urged. The object aimed at is to reduce completely all unimpacted fractures, and to hold the fragments in such firm contact that a kind of slight impaction is produced and bony union obtained. For this purpose he fixes the limb in its corrected position by a plaster-of-Paris splint carried from the toes up the limb and the trunk as high as the eighth rib, and down the opposite thigh as far as the knee. An interval is left in the plaster case over the great trochanter, and a pad worked by a screw on a steel arch attached to the splint is applied over this interval. When the plaster is set, pressure is made in the line of the neck of the femur by screwing down this pad. By this pressure the two fragments, which by the perfect reduction of the fracture have been brought into apposition, are pressed together, and are held as securely as if they were transfixed by a pin. In the *Journal of the American Medical Association* for August Dr. SENN describes fully this mode of treatment, and he details several cases in which he has applied it. He recommends that the same means should be employed when the fracture is impacted, as a security against disimpaction under the influence of the rarefying ostitis which accompanies union. Only, in cases of impaction no manipulation should be made to separate the fragments, and no efforts made to restore the length or the position of the limb. By this treatment it is stated that bony union can be confidently anticipated, that patients can be got up within a few days of their injury and so avoid all risk of hypostatic pneumonia, and that in many cases complete restoration of the function of the limb can be secured in the minimum of time. In its present form it seems to be a method that deserves careful trial, and if in other hands it is found as practicable and as successful as in Dr. SENN'S, that enterprising surgeon will have conferred a great benefit upon a large class of aged sufferers for whom surgery has hitherto done but little.

THE Report of Lord CAMPERDOWN'S Committee has been published, and the *précis* of their recommendations, which has already appeared in the daily press, has been read, no doubt, with much interest by the medical officers of the Public Services. It would be premature to forecast, much less definitely pronounce, what their verdict will be. Meanwhile, we will endeavour to summarise as succinctly as we can the impressions that we have ourselves formed in regard to those recommendations. The recent history of the Army Medical Service can be put into a nutshell. The circumstances under which the Committee was appointed are pretty well known. Until the appearance of the Warrant of 1879 THE LANCET used to teem with communications of complaint from army medical officers, and the unpopularity of the service was attested by the fact that it was being emptied at one end by retirements, and no candidates could be obtained to fill their places at the other end. What would have been the result had become tolerably obvious: the Army Medical Service threatened to resemble a derelict ship. The authorities had to do something. A new and most satisfactory Warrant appeared. Coincidently with the publication of that Warrant the popularity of the service was restored, and for years subsequently complaints from medical officers were "conspicuous by their absence" as far as our columns were concerned; candidates were forthcoming in adequate numbers and of excellent quality. Then came the action of the military authorities in regard to the question of relative rank. It was abolished, for no possible reason that we can see; and why this was done has never been explained, and probably never will be. All that is known is that the head of the department was never consulted before that step was taken. The illogical and anomalous character of the proceeding was rendered more conspicuous by the fact that to this day the rank, position—all, indeed, that appertains to the Naval Medical Service—remains about what it was, and is regulated by "relative rank," and the officers are well contented.

On the action taken at the time by a considerable number of army medical officers there is no need to dwell. Our opinion was not apparently in accord with that entertained by the majority of those officers, especially by those of the junior rank. We have no desire to deny it. The question is, was the majority right? And will the recommendations of this Committee—probably appointed mainly to consider this rank question,—in respect of the hybrid military titles suggested by them, content the medical officers, improve their status in the service, add to the dignity of their professional calling, and enhance their prospects, material or social, or will they not? But let us suppose that these titles—by which we shall have surgeon-lieutenants and surgeon-captains, and a deputy surgeon-general will henceforth be known as a surgeon-colonel—are deemed satisfactory. What about the other recommendations? The Army Medical

Digitized by Google

Service is not a corps, be it remembered; it still remains a department. For our own part we regard this Report as unsatisfactory and impracticable; and we think the Medical Service will regret that the Committee ever sat, for all the good it will do. The medical officers in the upper rank are, it is proposed, to serve for two years longer than they do now, by which the promotion of all the rest would be retarded in all grades of the department. A medical officer now enters with the rank of captain, whereas he would hereafter rank as lieutenant for the first three years of his service. This is to apply to the Army Medical Department, but not apparently to the Indian and Naval Medical Services! This, however, is probably simply an oversight on the part of the Committee, as such a regulation would cut off a supply of candidates for the army. It is recommended that medical officers should commence their service in, and be attached to, regiments for some definite period, a recommendation to which there can be no objection, except this—that it has hitherto been deemed financially impracticable; and the late reductions in the Medical Service have, it seems to us, rendered this still more so. If the civil medical element of this country is to be utilised to an increased extent, as suggested, it follows that this period of home service for medical officers will be shortened, instead of increased. Surgeon-General BALFOUR'S remarks in his protest on this subject are very pertinent. The substitution of officers on full pay to fill half-pay appointments will surely prove more costly. Some of the recommendations are no doubt fair and just enough, and meet with our entire approval; but they do not, after all, go to the root of the matter—at any rate, in this respect: that there is, literally, no reward for professional services, or for scientific attainments or professional culture, however conspicuous.

One word in conclusion. The Report of Lord CAMPERDOWN'S Committee is published; but what about the evidence on which the Committee drew up their recommendations? Is that to be published?

THE disclosures which have resulted from the appointment of a Commission of Inquiry into the Sweating System as carried out in this country must have prepared the public mind to receive with welcome any reasonable and effectual measure of reform. The Bill recently introduced into Parliament by Mr. BAUMANN does not therefore come altogether as a surprise, notwithstanding the drastic nature of some of its provisions. We may remind our readers that it proposes to extend the operation of the Factory and Workshops Act of 1878 to establishments hitherto exempted—namely, to domestic workshops (i.e., those in which members of the resident family are alone employed), and to workshops which do not give occupation to children and young persons. These it will at once be seen are the very shops in which sweating is most prevalent. Hitherto the right of mere entry by factory inspectors has been so carefully guarded by restrictions as to be of little real service, and the remedial power entrusted to these officials in dealing with any proved nuisance has consisted in an appeal to the local sanitary authority. By the terms of the new Bill it is proposed to allow the inspectors a right of free access to any dwelling used as a workshop, and authority to set in motion for themselves the legal machinery available for the correction of abuses. While deprecating the necessity for any such legislation as is contemplated by this Act, we confess that, in the absence of any spontaneous movement among tradesmen towards a voluntary adjustment of the existing difficulties, we can suggest no other alternative. We have repeatedly maintained, and we still maintain, that legislation in such matters, unless it be accompanied by active supervision, is of little value. It may seem to some that the Bill interferes unduly with the relations between employers and employed. This, however, is not the case. Its introduction is a simple consequence of existing mismanagement, and a protest which has long been called for in the mere interest of public health. Where the principle of "live and let live" is mutually recognised, the Bill will be practically inoperative, and employers who chafe at its restrictions will usually be found to be such as have rendered themselves liable to its needful control. A short Bill which proposes to limit the hours of underground work in mines to eight hours daily is likewise at present under consideration. The purpose of its promoters is good, but it is, perhaps, open to doubt whether a reduction of the nine hours' limit would result in any real advantage either to the health and well-being of the workmen or the interests of trade.

THE Infectious Diseases Notification Bill has been run through Parliament in a way that is not fit. The principles it involves and the details which it enacts were alike deserving of more consideration than it was possible for them to receive from members in the last weary days of a long session. It has been known for weeks that the Minister in charge of the Bill insisted on the dual notification, and that he would rather give up the Bill than pass it without making the medical attendant a party to notification. We have done our part to save the medical profession from this inconvenient and irksome duty. We have done this as much in the interest of the public as in that of the profession, believing that it was better to require of the medical man simply the certification of the nature of an infectious case, leaving the whole business of notification to be done by the householder. This plan should, at any rate, have been tried first. Had it failed, the profession would willingly have agreed to the dual system. But the Government have forced the Bill through in a way which we regret. Sir WALTER FOSTER, who raised the question of single notification, saw the way in which the Bill was to be passed, and abandoned the conflict, perhaps too quickly. Of course medical men will do their duty and obey the law, but it would have been better policy to have shown a little more regard for their feelings and their views of what is at once right and expedient. A minister at the tail end of a session is master of an obedient majority, but their obedience should not be abused; and it is within our knowledge that members of Mr. RITCHIE'S own party do not approve of this Bill or the way in which it has been passed. One suggestion of ours he showed himself willing to adopt, that it should be made of general obligation, and not dependent on the action of local authorities. But this concession, in the hurry scurry of legislation, had to be abandoned, and we have the anomaly of neighbouring communities being at liberty either to accept or reject this notification system, so that the good of notification in one place is largely neutralised

Digitized by Google

by its absence in another. Mr. RITCHIE was willing to let off any place as regards adopting this measure, but he would on no account exempt the medical man from the duty of notification where it is adopted. This, we repeat, is much to be regretted.

One thing is remarkable in this legislation: the slight resistance which politicians of advanced views have been able to offer to its fundamental principle—viz., the right of the community to insist on knowing the affairs of individuals and families where these are likely to involve in any degree the health of others; in other words, the subordination of the individual to the community. This is of course the fundamental principle of society, but it is ever undergoing fresh development. National education, vaccination, isolation, and notification of disease are all illustrations of the same principle. Strange to say, the inhabitants of Leicester are quite ready to enforce notification and its consequence—isolation,—while they shrink from compulsory vaccination. We have ourselves no hesitation in accepting the principle that individual liberty must give way where such doubtful advantages as the freedom to have small-pox and scarlet fever are the only badges of liberty. And it will involve no misfortune to the world if many other rights claimed by well-meaning but discordant individuals are curtailed in the interests of society.

Annotations.

"Ne quid nimis."

THE STUDY OF THE HISTORY OF MEDICINE.

MR. LLOYD OWEN'S address on the Value of the Historical Study of Medicine (*Birmingham Medical Review*, July) points to the profit and pleasure obtainable from such a study, which assists in maintaining definitely the idea of continuity with the past, and he regrets the lack of opportunity afforded in our medical centres for the pursuit of this subject. A just estimate of the failures of the past would, he maintains, correct the "restless and unwholesome desire for novelty which is one of the weaknesses of the present age"; and we are inclined largely to agree with him. An infinity of trouble and ingenuity would be saved if the medical profession could take more to heart the lessons gained in bygone days, in matters of practice as well as in matters of theory. Even the Asclepiadæ (500 or so years B.C) were careful to select salubrious sites for their temples, where the treatment of the sick and clinical instruction were carried on. In very early times also the profession had to be protected by legal safeguards from unqualified practitioners; but Mr. Lloyd Owen thinks that the physicians of those days were less devoted to the service of man at their own risk than at present. He singles out from the writings of Hippocrates the statement that all diseases are "alike divine, for each has its own nature, and no one arises without a natural cause"—an idea which, had it been fully grasped by his successors, would have made the progress of medicine far more rapid. He alludes also to the advice given by Hippocrates to make the basis of preliminary education as wide as possible; so that in urging this now we are only following in the path of the ancients. Specialism, he shows, is as old as medicine itself, for "Herodotus tells us that among the Egyptians each physician applied himself to one disease only. All places abounded in physicians—some for the head, others for the eyes, others for the teeth, others for the parts about the belly, and others for internal diseases." The influence upon medicine of prevailing philosophies is illustrated by its association in mediæval times with alchemy, Rosicrucianism, and magic, which gave way to rational and experimental methods based on anatomy, physiology, and the natural sciences. Mr. Lloyd Owen deserves thanks for directing attention to this neglected subject, which he claims to have real, practical, and also moral advantages; and he urges the establishment in every University and every medical school of a professorial chair of the History of Medicine, suggesting that such a course might most fitly be taken by the student in his final summer session, or, failing that, that it should form part of a post-graduate course. The suggestion is one which merits the fullest consideration, and we would urge the universities to institute such professorships. There are several members of the profession who could most ably discharge the duties of such chairs.

DEATH OF A HOUSE SURGEON FROM DIPHTHERIA.

WE regret to have to record that another house surgeon, Mr. Charles Brown, M.R.C.S., L.R.C.P., has succumbed to an attack of diphtheria contracted during the course of his duty. He had held the post of house surgeon at St. Thomas's Hospital for nearly the full period of time for such appointment, and had become out of health in consequence of close application to the duties of his office, so that he fell a more ready victim to the disease, which assumed a very malignant type. He had assisted in the performance of tracheotomy in a case of diphtheria two days before his illness developed, and had been in attendance on the case afterwards. On the morning of the 21st he suffered from sore-throat, but was able to do his work, and assisted at another tracheotomy for diphtheria; about midday, however, he became suddenly very ill, with frequent vomiting, rigors, intense headache, and pains in the limbs. In the evening the temperature was 102·5°. On the 22nd there was great œdema of the palate and fauces, and membrane was visible in the pharynx. On the 24th he was unable to swallow on account of the pain and swelling in the throat. By the 25th the membrane was spreading across the palate, and there was a discharge from the nose. He coughed up a cast of the trachea and shreds of membrane. Air did not enter the lungs well; there was some lividity of the face, and a trace of albumen in the urine. In the evening he was better, and was able to swallow fluids well, but rapidly became worse at 11 P.M., and passed into a state of unconsciousness with stertor and laboured breathing. Early on the following morning (the 26th) laryngotomy was performed, but no improvement followed the operation, and he died at 3 A.M. The illness throughout was of a malignant character and attended with much loss of strength. He was under the care of Dr. Hadden, who, with Dr. Turney (house physician), was in constant attendance. Mr. Pitts performed the operation. Mr. Brown had been a prosector to the Royal College of Surgeons, and had held other offices at St. Thomas's Hospital, having been assistant demonstrator in Practical Surgery, clinical assistant in the Throat and Ear Departments, and assistant house surgeon. His death has cast quite a gloom over the hospital, in which he was so well known and highly esteemed for his excellent qualities, both professional and social. Our readers will recollect that last year we had to record the death of a house surgeon at Guy's from this cause. Diphtheria is a serious risk to men holding such appointments, who are necessarily exposed to the disease, and we would urge on those having authority the wisdom of sending the house surgeon away at once when evidently suffering from the effects of too close application to duty. A suggestion of rest and change

Digitized by Google

of air, much as it may be needed, will not come from the house surgeon, who would rather go on as long as he is physically able to perform his duties.

A correspondent (C. T. Q.) writes in reference to the above sad event as follows:—"Other and weightier pens may bear their witness to the excellence in professional work of the late Charles Brown, to his steadfast, honest, and brilliant student career, and to his success as house surgeon to St. Thomas's Hospital, at which post he met his death. But as one very closely associated with him for many years I would speak of his character as a man. To all alike—staff, colleagues, and patients—he was the same, courteous, gentle, and sympathetic, and amidst the rivalries, fierce at times in a great hospital, was only regarded with friendship and admiration. His more intimate friends cannot yet realise that they are robbed of his genial presence, and that his voice, so often charming us with a wit peculiarly his own, is stilled for ever. He had exceptional musical talents, exercised first in the choir of the Chapel Royal, Whitehall, later on as organist at St. Mark's Church, Wandsworth, and quite recently in the same capacity in the Hospital Chapel. At one time Music had nearly claimed him as a student; but Medicine won him, heart and soul; for her for many years he lived, and for her he died."

WARM BATHS IN TYPHOID FEVER.

DR. ANUSCHAT advocates, in a communication to the *Deutsche Medicinal Zeitung*, the employment of warm baths in typhoid fever in place of the cold water, to which the patients often evince such a great objection that they refuse to re-enter the bath. He disputes Brand's doctrine that the good effect of the cold bath is due solely to the low temperature, as in that case it would be equally advisable in all acute fevers. Dr. Anuschat believes the beneficial effect to be due to the water rather than to its temperature, and his view is confirmed by the results of 150 cases which he has treated with the warm bath. He administers three baths daily, from fifteen to twenty-five minutes each, at 95° F. if the temperature of the body is between 100·4° and 100·2°, at 93° if the body temperature is 102·2° to 104°, and at 90·5° only if the temperature of the body is higher than 104°. In most cases a perceptible improvement takes place in three days, with decrease of fever, but the good effect of the warm-bath treatment is most plainly seen in the almost entire absence of secondary symptoms and the much shorter duration of the illness. Of 150 patients, 145 were less than four weeks confined to bed, and most of them less than twenty-one days. When the temperature of the body falls below 99·5° the bath is administered less frequently. The treatment—medicinal, dietetic, and stimulant—recommended is much the same as that generally prescribed.

THE CRUELTY TO CHILDREN BILL.

AFTER a somewhat uncertain course the Prevention of Cruelty to Children Bill has passed both Houses of Parliament, and has received the Royal sanction. The new Act, if administered with reasonable energy, should prove a most useful measure. It increases greatly the power of the law in dealing with the careless or wanton ill-treatment of children. A special and heavy fine and a term of imprisonment will be exacted in any case where the life of a child so used has been insured. The responsibility for any proved instance of cruelty will rest upon the temporary custodian of the child, whether a relative or not. On the other hand, it will be lawful to transfer children from the custody of a harsh guardian to various other persons defined by the Act. So much for the general treatment of the children. Another important section is that which deals with their occupation. Child-begging will be held to be an offence on the part of parents or guardians, and juvenile hawkers will be placed under the control of local authorities, the liability for offences against the terms of this Act resting upon the employers of these children. No child under ten years of age will be allowed to labour for profit, except in particular cases where the employment of younger children in theatres under the supervision of factory inspectors is permitted by special licence. Any person observed ill-treating a child in any way is liable to summary arrest, and incurs the statutory penalty. Children who are called upon to give evidence against their parents in respect of cruelty may be removed from their custody pending the hearing of their case. A statutory oath will not be required of them. The evidence of one parent against another will be accepted, and the accused may give evidence on his own behalf. This brief recapitulation will suffice to show that we have here an Act both temperate and effective, and one which cannot fail to add greatly to the now very stinted happiness of many young lives.

ACCIDENT INSURANCE.

THE two actions in which the Accident Insurance Company has successfully resisted claims made under its policies will redound, no doubt, to its immediate advantage, inasmuch as it escapes a present liability for sums amounting in the aggregate to £2000; but we should think that it will suffer, and not it alone, in public estimation, as the result of the exactitude with which it has stood upon its rights. In one case (Cornish *v.* the Accident Insurance Company, Limited) the claim was resisted on the ground that the policy-holder had incurred obvious risk, the fact being that he had incautiously crossed a railway passing over his land immediately in front of an approaching train which it is supposed that he did not see until too late. It is of course quite reasonable that the Company should refuse to take a risk of this sort if the limit of its responsibilty is clearly understood. The class of accidents to which the negligence of the sufferer contributes is perfectly distinct from that still larger class of such as arise from circumstances wholly beyond his own control, or as consequences beyond the range of calculation of his own acts. If the parties to the insurance contract choose to exclude the former class of accidents from their agreement, there can be no reason why they should not do so. But such a policy is probably a very undesirable one for ordinary purposes. Negligence is an item in so many accidents that the policy-holder who is not protected against its consequences is but very indifferently secured. On the other hand, wilful negligence or the fraudulent submission to personal injury is not only very rare, but generally capable of all the proof necessary to secure a company against any unreasonable risk. In the second case (Cole *v.* the Accident Insurance Company, Limited) death had ensued from the inadvertent drinking of a solution of corrosive sublimate. The accidental character of the occurrence was not disputed. The policy-holder had gone with a lighted candle into a stable for the purpose of taking a dose of some medicine kept there. The candle had been blown out by a gust of wind, and the deceased, groping in the dark for his medicine, took down a bottle of horse-lotion in mistake for it, and dosed himself, as already mentioned, with corrosive sublimate. The plea in this case was not obvious risk, but poisoning, for it appears that the Company's policies contain a proviso to the effect that the Company shall not be responsible in the case of death from poison. This seems to us to be an absurd condition, and one that no sensible person would knowingly accept. In delivering judgment in favour of the Company, the Master of the Rolls is reported (*The Times*, Aug. 10th, 1889) to have said that "he had a prejudice against this policy, and

Digitized by Google

it was an honest, right, and judicial prejudice. When he saw a policy which ordinary people would consider insured them against accident, and when he saw that the policy was drawn in such terms that it would not secure them against almost every kind of accident, it was a policy not to be praised, and people ought to be warned against insuring under policies in that form. This policy was one that might deceive persons of ordinary intelligence." These are undoubtedly strong comments, and we notice that they called forth a disclaimer from Lord Justice Bowen, who said, "As he was unable to agree with the observations made by the Master of the Rolls upon this policy, he considered it a matter of justice to the Company to say so"; but, for our own part, we are bound to say that we strongly feel what the Master of the Rolls so forcibly expressed.

ENTERIC FEVER IN NEW SOUTH WALES.

MANY places in our Australasian colonies have for some years past suffered much from enteric fever—the disease which, of all others, is typical of an imperfect sanitary administration; and several colonies have decided that very stringent measures as to water-supply, sewerage, drainage, and excrement disposal must be taken in order to get rid of this highly preventable scourge, which is so fatal in its influence on life at the young adult period, when life can least be spared. One recent contribution dealing with this subject comes from Dr. Ashburton Thompson, deputy medical adviser to the Government of New South Wales, who, together with Mr. George H. Stayton, Government engineer, reports on enteric fever in New Town and Macdonaldtown. To those acquainted with the conditions which favour the spread of enteric fever the report will only cause amazement that, under conditions of life so different from those which we have in this country inherited from an ignorant age that is now passed, circumstances so obviously tending to the maintenance and diffusion of this filth-disease, can have been allowed to grow up in such abundance. It almost seems that the Government have not as yet even secured proper powers for dealing with such matters in a comprehensive and systematic manner. If this be so, it is to be hoped that the force of Dr. Thompson's trenchant and timely exposition and warnings will be recognised in such manner that preventive measures may be put into operation without further delay.

NO ONE RESPONSIBLE.

THE story elicited at a coroner's inquest at Grove Park, Lee, affords an illustration of the manner in which responsibility for conditions fatal to health and life is shifted about from one person to another. An infant has its milk mixed with water from a filthy pond; it has diarrhœa and dies. It then transpires that all the family drink the water, that all have been suffering from diarrhœa more or less, and that the water is used in other households also. Mr. Larkin, having frequently had to attend people who were sick and who used this water, very properly brought the matter under the notice of the coroner, and at the inquest no one seems to have regarded himself as the person responsible for a condition that ought to have been notorious to all concerned. The water was found to be green in colour, and full of tadpoles, animalculæ, and filthy impurities; but the sanitary inspector for Lewisham, who said he had been in office for ten years, knew nothing about it. Evidently no house-to-house inspection, with the corresponding record of local sanitary conditions, is made in this district. Then came the representative of the nobleman to whom the property belongs, and he, too, knew nothing about it; and, indeed, he disclaimed the intention of making any speech "of the nature of a defence." The medical officer of health had also apparently no knowledge of the matter, for it was announced that his attention should be drawn to it, and the inspector added that a sample of the water should now at last be submitted to an analyst. So far as our knowledge goes, the sanitary authority, their officers, and the landlord all have a very definite responsibility in the maintained use by cottagers of such a water-supply, and this the more so because of the occurrence taking place within a few miles of London-bridge, and in a place where the Kent company's service is available. The danger as to improper water-supply does not appear to have been limited to the cottages alone, for the attention of the inspector of dairies and cowsheds under the London County Council has now been directed to the matter, and it was only on this assurance, coupled with the promises made by the sanitary inspector and representative of the landlord, that the jury decided, on the advice of the coroner, to close the inquiry by finding a verdict in accordance with the medical evidence.

WILD FLOWERS BY THE (RAIL)WAYSIDE.

WE are pleased to notice in that bright and pleasant little periodical, the *Selborne Magazine* (for August), a contribution from our friend Mr. Henry Smith, who has frequently shown how devoted a lover he is of nature, and whose contributions to natural history are known in some circles as widely as his surgical performances are known amongst his professional brethren. The article in question is descriptive of the varieties of wild flowers to be seen on railway embankments, and contains some suggestive remarks as to the operation of the law of natural selection in the kinds of plants met with according to the nature of the soil and situation of the embankment or cutting. As Mr. Henry Smith observes, the tedium of a long journey may often be relieved by the observation of the floral display that passes before the traveller's eyes, and he is justified in his preference for the wild profusion of the "negligence of nature" to the trimly cultivated garden. Railway travellers cannot do better than follow his example, and cultivate their powers of observation in preference to limiting their range of vision to the pages of a book or newspaper. The same number of the *Selborne Magazine* also contains an instalment of "Reminiscences of Charles Waterton," by another well-known member of our profession, Dr. George Harley.

THE LUNGS AND LIVER IN PHTHISIS.

DR. PLESHIVTSEFF (*St. Petersburg Dissertations*, 1888–9, No. 85) has weighed and measured the lungs and liver in eighty cases, forty-eight of which had died of phthisis. These weights and measurements are, in the tables he gives, all reduced by calculation to a common standard of height—viz., 100 centimetres. Thus, in the body of a woman 150 centimetres in length, all the weights and measurements are reduced to two-thirds of their actual value. In this way a fair comparison may be made between bodies of different sex and size. The total volume of the lungs in phthisical subjects was found to bear to that of non-phthisical subjects the ratio of 2414·8 : 2107·5; the volume of the liver in the two classes of cases had a ratio of 1404 : 1270. The lumen of the aorta was greater in the phthisical cases than in the others in the proportion of 65 : 79, and the circumference of the bronchi in the proportion of 70·8 : 81·1. Another table gives the ratio of the circumference of the bronchi and pulmonary artery to the volume of the lungs, and of the circumference of the portal vein and of the hepatic artery to the volume of the liver. The mean results obtained were that, in the phthisical cases, the bronchi were 1·29th and the pulmonary artery

Digitized by Google

1·34th of the lung volume. (The one measurement is linear, the other cubic, but this does not affect the comparison which the author wishes to draw.) In the non-phthisical cases the fractions were 1·25th and 1·29th respectively. The mean circumference of the portal vein was 1·36th of the volume of the liver in the phthisis cases and 1·30th in the others. The hepatic artery was also relatively smaller in the phthisis cases, being 1·46th in them and 1·32nd of the volume of the liver in the others.

REPUTED CASE OF HYDROPHOBIA.

THE great interest which has been taken in the subject of hydrophobia outside the medical profession was sure to lead to simulation of the disease, at all events as regards some of the more marked symptoms. A recent example of this was quoted as a real case, arising under circumstances of a peculiar character. The main facts appear to be that a man, who had taken "three two-penny-worths of gin, suddenly fell down in the hotel and became very violent." About half-past five he began to breathe heavily, when the sound resembled the growling and barking of an infuriated dog. He snapped at and tried to bite the persons surrounding him. He was then conveyed in an ambulance to St. Thomas's Hospital, where he continued violent, vomited, and had attacks of shivering. When admitted to that hospital there was slight inspiratory stridor, and falling water irritated him; once there was opisthotonos. After two days in bed and treatment with bromide of potassium he quite recovered. The possibility of hydrophobia was only suggested to the hospital authorities, as the man said that he had been bitten by a mad dog seven weeks previously. Six weeks before this there had been another similar attack treated in the infirmary. He appears to have been placed in the strong room, but left at the end of three days. He said that he had had three other fits at long intervals. We recollect having seen a man enter a crowded out-patient department on his hands and feet, barking like a dog; the other patients scattered themselves to the right and left to escape the supposed madman, and were much surprised to see him walk away in a few minutes, quite recovered from the attack.

SCOTTISH FISHERY.

THE seventh report of the Fishery Board for Scotland shows that this important industry continues to develop, and upon the whole satisfactorily. It may well be doubted, however, whether better improvement might not be looked for than the Board is able to report. The problem of feeding the multitudes cannot be solved without the help of the fisherman; and, though much has been done in recent years to aid and extend the fishery industry all round our coasts, we cannot but feel that, alike on the part of the public and of the Government, there is some lack of appreciation observable in reference to the inestimable boon of proffered food which the sea tenders on our shores. For example, reference is made in the present report to a systematic extension of the telegraph system to remote fishing districts which the present Board has undertaken, and the district of Barra is particularly mentioned by way of illustration. Here we read that in 1884 the cable was extended to Castle Bay, Barra, under a guarantee given to the Postmaster-General by Lady Caithness and the Board, "which has cost the Board upwards of £500 a year for their proportion of the loss consequent upon the extension." The report goes on to show that this cable has been invaluable to the fishermen at a time of emergency during the past year, as may well be supposed. With the fact stated, and with the substance of the comment upon it, we have no fault to find, but it does appear to us that the pointed reference to £500 a year in connexion with so necessary a part of the equipment of the fishing village betrays a little disposition towards cheese-paring, which is, indeed, characteristic throughout of the relations of the Government with the fishing community. Were fish a costly luxury, the men who win it would receive more respect and consideration than they do; but, since its cheapness is its greatest merit, there is something both ungracious and blind in the tardy and apathetic attention which the craft of fishery receives at the hands of the public and their official representatives.

FAITH CURES AT LOURDES.

MORE miraculous cures are reported from Lourdes. Two of these in particular have lately attracted attention; in one case a navvy paralytic in consequence of an accident, in the other a girl blind for two years, having, it is stated, recovered the use of their suspended functions. We are not disposed to deny the possibility of "miracles." On the contrary, we will venture to assert that in some sort or other they happen every day, and almost everywhere; for while the world endures we are certain to hear the true saying that "wonders will never cease," and a miracle professes to be nothing more than a wonder among the processes of nature. The wonders of the grotto at Lourdes are similar to those with which faith healers in this country have made us familiar. It will be noticed that they have arisen out of the same fertile soil—the mutability of a diseased nervous system. It must not be forgotten that nerve pathology includes many cases in which the distinction between functional and organic disease is by no means well marked. Yet the difference is an important one. Under the former title are included a variety of unstable morbid changes capable of rapid and even total transformation; under the latter, a group in which the possibilities of improvement are inversely proportional to the organic alteration. Such evidence as can be gleaned from the practice of the faith cure, equally with the clear testimony of scientific fact, forbids us to doubt that the wonders wrought at Lourdes owe their occurrence mainly to the influence of the sufferer's will, refreshed by hope and acting on the sources of non-organic paresis. Such an explanation is acceptable both by faith and science. It does not destroy the "miracle." The wonder still remains, but its mechanism is seen to be natural, and thus, in the words of the apostle, "the things which are invisible are understood by the things which are made."

PATHOLOGICAL CHANGES IN THE RETINA IN CEREBRAL AFFECTIONS.

DR. I. S. FELSER, late chief of Professor Adamiuk's ophthalmological clinic in Kazan, who has recently been engaged in researches on the pathological anatomy of the eye in St. Petersburg, publishes some of his results as a graduation dissertation (*St. Petersburg Dissertations*, 1888–9, No. 61). The cases he examined post mortem included examples of several cerebral affections. A number were cases of meningitis (tubercular and simple), and in all of these there was effusion into the sheath of the optic nerve, with œdematous neuro-retinitis. There were also cases of chronic meningitis, of arterio-sclerosis of the brain, and of cerebral hæmorrhage. The results of the examinations appeared to show that all diseases of the brain and its membranes, with impairment of its general structure, are accompanied by signs of acute inflammation with œdema of the optic nerve and retina. Chronic inflammations of the cerebral membranes were found to produce diffused chronic retinitis. Arterio-sclerosis of the cerebral vessels was found to extend to the vessels of the optic nerve and retina, and always to induce peripheral œdema of the latter,

Digitized by Google

this œdema being considered by Dr. Felser to arise from chronic venous hyperæmia, on account of the general interference with the circulation. Where there was arteriosclerosis of the brain together with extravasation of blood into the substance of the brain, there was always found extravasation into the retina, due to the formation of capillary aneurysms of the branches of the central artery. The so-called "Stauungspapille" (choked disc) are to be explained by the compression exercised on the optic nerve at its exit by the accumulation of pathological fluid under its sheath.

ANATOMICAL APPEARANCES RESULTING FROM POISONING BY ARSENIC.

AT the close of a paper on the above subject, read before the Massachusetts Medico-Legal Society (*Boston Medical and Surgical Journal*, Aug. 8th), Assistant Professor F. W. Draper, M.D., makes the following instructive remarks:—

"Is post-mortem diagnosis of arsenical poisoning an easy matter? That is to say, assuming ..... that we are in the presence of a dead body of whose clinical history we know nothing, are the revelations of the autopsy sufficiently characteristic and unequivocal to warrant one in concluding readily that the death was by arsenic? The answer is in the affirmative, upon the single condition that the data are studied in their associated relation, and that their collective significance is the evidence which guides the examiner. There is no single organ whose testimony is sufficiently conclusive to control the diagnosis, with the possible exception of the finding of deposits of the poison upon the gastric mucosa, with a marked degree of inflammatory redness beneath and around them; but, short of this, the condition of the stomach, however striking its inflammatory character may be, is suggestive only, the various degrees of irritant effects being explainable by numerous causes other than arsenic. But when, in addition to the presence of gastritis, the pathologist finds fatty degenration of the heart, kidneys and liver, a fluid and dark condition of the blood, and subendocardial ecchymoses, he may with clear conscience testify in court that he is of the opinion that the death was by arsenic. In this conclusion he would probably be confirmed by the results of a properly conducted chemical examination of the viscera. Indeed, without the gastric and enteric data, or with only an insignificant and equivocal degree of inflammatory reddening of the mucous membrane of the digestive tract, the concurrence of fatty changes in the heart, kidneys, and liver should arouse the examiner's suspicions, and suggest to him the propriety of seeking the chemist's aid to verify his surmises."

CLIMATOLOGY AT THE VATICAN.

WITH an enlightened liberality not always associated with the tiara, the Pope has taken steps to put the Meteorological Observatory at the Vatican on a thoroughly scientific basis, and has entrusted the undertaking to the Padre Denza, one of the leading climatologists in Europe, who will also assume the direction of the establishment when completed. As subordinate coadjutor, the Padre Laix will take the next position on the effective staff of the Observatory, which will thus be entitled to rank as the best equipped institution of the kind in Italy. To enter on his new office, the Padre Denza must resign his post as Director of the Royal Italian Observatory at Moncalieri, near Turin, and in this transference of his services from King Humbert to Pope Leo "political meteorologists" have already found food for congenial speculation. The Pope, however, in matters of pure science has more than once evinced his absolute unconcern as to their presumable bearings on policy. In fact, he has just authorised the Padre Denza to represent him at the Meteorological Congress to be held next month in Paris, thus dissociating himself from other European potentates (Catholic as well as Protestant) who decline to recognise the claims of science when put forth concurrently with the celebration of the anniversary of the French Revolution.

TONGUE-TIE.

DR. TASSIUS of Berlin, in a communication to the *Memorabilien*, makes himself responsible for some novel views on the propriety or otherwise of incising the frænum of the tongue. He says in his introductory remarks that the little operation has often been performed without considering that other and deeper causes, especially those connected with the general development, may be accountable for the faulty development of speech than the mere size of the frænum. He considers that this tiny and admirably constructed organ is a correct regulator of the various movements of the tongue, and that, if the same be too hastily interfered with, the more delicate movements may be for ever destroyed—a momentous fact for those who are destined to become public singers. He advises his medical brethren, therefore, to proceed very cautiously, and not to operate at too early an age, as much improvement may result from the advancement of general development. Only in those cases in which the frænum is so abnormally large and tendinous as to cause a fissure in the tip of the tongue may the incision be made at once, but it should be calculated almost mathematically what proportion the depth of incision should bear to the fissure. The author deprecates, therefore, the use of scissors, as not to be depended on, but advocates the employment of a small knife, the incision to be made from below upwards. Where the frænum is of a fleshy character, and it is, consequently, certain that the child will never gain distinction in singing or elocution, there is, according to Dr. Tassius, no cause at all for immediate interference, unless the deformity causes a real impediment. It is far better to leave such cases—at any rate, for some time—entirely to the *vis medicatrix naturæ*.

THE DOCK STRIKE.

THERE seems to be a pretty general agreement of opinion that the present strike of dock labourers is not merely a fretful outburst of wanton discontent, but is founded to some considerable extent on the existence of real grievances. We have already shown, in the report of THE LANCET Special Commission, Dec. 8th, 1888, that the life of these men is, in a greater degree than that of many workmen, one of hardship, irregular employment, and insufficient pay. Accidents are exceedingly common, and often serious. In a good many cases they might, with better oversight of the modes of working and of the gear employed, be avoided; and they are often also the preventable consequences of sheer weakness in men irregularly occupied, underpaid, and therefore underfed. In these circumstances, it is easy to understand why the sympathy which is felt for this class of workmen exists as a general impression in different sections of the community. Many persons, who may not be able fully to appreciate the import of their specific demands, feel that, at all events, some substantial concessions are necessary. In this, doubtless, as in every question, the interests of both parties in the matter have to be considered. Some allowance is due to the dock companies as well as their *employés*. Neglect and accident will occur under the best management; irregularity in work may be a consequence of personal incapacity or sheer laziness; and wages must to some extent be regulated by considerations of a dividend. Still, after every allowance, it must be admitted that grievances do exist, and it is to be hoped, as much for the companies' credit as for the good of their workmen, that these will be remedied by adequate and

Digitized by Google

early concessions on the part of the former. The one objectionable feature in all strikes—the practice of preventing by intimidation or by force the employment of substitute workmen—has not been so offensively prominent on this as on some other occasions. A tendency towards its adoption has, however, been more than sufficiently apparent, though, we may reasonably expect that, in view of the consenting attitude of public feeling, the purpose of legitimate combination will not be crossed by a method so violent and unjust, and so fruitful in ultimate failure.

DEATH OF DR. HABERSHON.

THE public, the profession, and the College of Physicians will deplore the loss of Dr. Habershon, whose death occurred at Brook-street on the 22nd inst. The illness to which he finally succumbed first made its appearance some twelve months ago in the form of repeated attacks of indigestion. In November last he was prostrated by a serious attack of hæmatemesis. In spite of this, he recovered sufficiently to resume work. In April, however, the close attendance upon and death of Mrs. Habershon led to a renewed period of ill health, which culminated in a return of gastric disturbance. Frequently recurring hæmorrhage, dislike of and inability to retain food, quickly reduced his strength, notwithstanding all that the kind care of his medical friends could devise. His death occurred from exhaustion, and within a few days of his sixty-fourth birthday. Thus has passed from us one whom we could ill afford to lose—one who had made his mark amongst his contemporaries, not only as a well-known writer and a shrewd and careful observer, but as a man whose high principle, rectitude of conduct, and sterling friendship gained him alike honour and respect throughout a long and brilliant career. We hope in an early issue to give further particulars of his life.

BILLROTH ON THE DANGERS OF CARBOLIC ACID.

THE following letter of Dr. Th. Billroth of Vienna has been published: "I have lately seen four cases, in which fingers which had suffered a most insignificant injury became gangrenous through the uncalled-for application of carbolic acid. Carbolic acid is now much less used in surgery than formerly; we have only gradually become acquainted with its dangers. The acid may not only cause inflammation and gangrene, but also blood poisoning, and so may even prove fatal. It is useful only in the hands of a skilful surgeon, and ought never to be used without his advice. The best lotion for recent injuries is the ordinary lead lotion, which can be bought at any chemist's. The best antidote in carbolic acid poisoning is soap, which should be taken immediately and repeatedly until all symptoms of poisoning have disappeared."

THE DERBY GUARDIANS AND THEIR MEDICAL OFFICER.

IT would be gratifying to be able to assure ourselves that the relations between boards of guardians and the gentlemen whom they have chosen to take charge of the medical interests of the parish poor were generally of so happy a kind as those which appear to subsist between the Derby board and their medical officer. At a recent meeting of this board, Mr. Gentles took occasion to refer to the lengthened period (twenty-one years) for which he had, with uninterrupted satisfaction to himself, served them in the capacity of medical officer. During that time, he said, he had paid no less than 110,000 visits. The Rev. W. H. Tetlow, with the hearty concurrence of his fellow-guardians, congratulated Mr. Gentles on the attainment of his majority in the service of the board, and expressed his confident hope that the cordial understanding which had heretofore reigned between themselves and their medical officer would be maintained in the future.

LEPROSY AT THE CAPE.

THE September number of *Blackwood's Magazine* opens with a short descriptive article upon Robben Island, near Cape Town, which is inhabited by a population that consists "approximately, of 130 lepers, 230 lunatics, 30 convicts, and 160 police and ward-masters." There are two resident medical men, the senior of whom is governor. The writer gives a somewhat too realistic description of the leper wards and their inmates, and, be it noticed, cites the opinion of the doctor who accompanied him in his visit—that he has "no shadow of doubt" as to leprosy being contagious. On the testimony of this writer, the "hospital" consists of nothing but crazy sheds, destitute of commonest furniture and fittings, and over-crowded with the sick from this dreadful disease. The article is headed "Wanted, a Father Damien"; but even a man of that devoted type would have hard work to secure the comfort and decency which the authorities of this colony of Great Britain seem according to the writer of the article to refuse to these poor outcasts. We are willing to believe that this may be only one of the many examples so common in our midst of the evil that is wrought by "want of thought," for it would be impossible that the sufferings of the leper should fail to awaken sympathy even in the official breast. Allowing, too, for the unconscious exaggeration of a visitor brought face to face with a leper colony, the article contains statements which should lead to immediate steps being taken to investigate the alleged deplorable conditions existing in the place.

GRAVES'S DISEASE.

A CASE of Graves's disease in the Academical Hospital at Upsala, under the care of Dr. I. Aug. Hammer, tends to confirm Benedikt's view that the cervical branch of the sympathetic is not affected in this disease. *A priori* it seemed probable enough, as exophthalmos had developed more rapidly on the left side, and at the same time sensibility over the superior cervical ganglion of the left side existed, together with long-standing headache affecting the left side, and partaking of the character of paralytic hemicrania. The result of microscopic examination was, however, quite negative. In twenty-two post-mortem examinations in Graves's disease published from 1860 to 1887, the sympathetic nerve was found quite normal in fifteen; in the other cases, either unilateral atrophy of the nerve elements—especially of the ganglion cells—was found, or the connective tissue was hypertrophied, or these two conditions coexisted.

SEA-BATHING FOR CHILDREN.

IT would be needless and vexatious alike to children and parents who yearly enjoy a holiday at the coast if we were to picture in graphic detail all the possibilities of injury which there, as elsewhere, abound. Sunstroke, the risk of catching cold, of falling into the sea from piers, rowing boats, or sailing boats, and many more accidents both within and out of doors, need not now receive from us a more than passing mention. Sea-bathing is in itself a fertile theme. There is in this connexion one point in particular to which we would direct attention. A contemporary writes at some length in condemnation of the common custom of ducking and forcibly bathing young children in the sea. He objects to this, not unreasonably, on the ground that the beneficial effect of bathing depends chiefly on its influence as

Digitized by Google

a cardiac tonic. This advantage, he observes, is largely discounted by nervous depression when a child, already scared at the sight of what seems a wild waste of water, is further terrified by rough-and-ready immersion. There is truth in his argument that there need be no difficulty in bathing even such children if their education in the art be carried out by more persuasive methods. In cases of this kind any known constitutional timidity should have ample consideration. At the same time it is most necessary to distinguish between this and mere passionate disinclination. In the latter case a disappointment of the will is itself a useful lesson in obedience. More than this, there are even children of naturally diffident character, but otherwise healthy, for whom a prescribed sea-bath under moderately rigorous management provides an ultimately useful tonic. In all such cases much will depend upon the judgment of the persons immediately responsible. It follows, from the above remarks, that any who may be thus placed should study closely the characters of their children, and guide their conduct accordingly.

EFFECTS OF ALCOHOL IN MODERATE QUANTITY.

DR. MOGILIANSKI (*St. Petersburg Dissertations*, 1888-9, No. 87) has investigated, in a painstaking manner, the effects of alcohol as a beverage on persons who are and who are not accustomed to it. He selected as his subjects nineteen healthy young men, mostly students, and estimated the constituents of their food and also their urine and fæces for several days with and without alcohol. He found that the temporary use of moderate quantities of alcohol in those accustomed to it improved the appetite and increased the assimilation of nitrogenous principles; but that in persons not habituated to its use the assimilation of nitrogen decreased. Alcohol appeared to diminish the assimilation of fat. The destruction of the albuminoids in the body always decreased with moderate doses of alcohol, and frequently even with small ones. No diuretic action was observed; indeed, the amount of urine passed by the subjects while they were taking alcohol was less than when they did not take it. The quantity of alcohol given per diem—usually in the form of vodka—varied from 60 to 140 cubic centimetres.

BURIAL REFORM.

THE Rev. F. Lawrence, the indefatigable Secretary of the Church of England Burial Reform Association, informs us that it is their intention to ask for an interview with Lord Salisbury. The object of this is to urge upon the Prime Minister the importance of taking steps for the protection of the public against the dangers involved in the continued general use of such cemeteries as Brompton, Tower Hamlets, and others. The returns recently furnished of the numbers interred in these and other metropolitan cemeteries, which were obtained at the instance of the Association and published in THE LANCET of Aug. 17th, show that the dead lie in and around London to an extent which it is almost appalling to contemplate. Were they all properly buried it would be serious enough; but when it is remembered that a vast proportion are not really buried at all, but boxed up in lead coffins and deposited in vaults—in other words, entombed in such manner as to cause, sooner or later, noxious emanations of poisonous gases,—it becomes manifest that the subject is one for legislation. The Association has already done an excellent work in drawing attention to the evil, which is intensified in the cemeteries and other burial grounds near large centres of population. But, though intensified there, the evil is not limited to urban districts; over-crowded cemeteries, church- and chapel-yards, may be found in localities where they would be least expected. The Home Secretary has ordered the churchyard of Wetheral, a most picturesque village near Carlisle, to be closed at the end of this year; and it is an indisputable fact that in this same churchyard, so far back as thirty-five years ago, human remains were disturbed and turned up in reopening old graves and in digging fresh ones. It ought to be generally known that any disturbance of a human body once buried, except by an exhumation order from the Home Office, is contrary to law, and the appearance of bones in digging a grave is *primâ-facie* evidence that the burial ground is already full enough, and should be closed. We hope, therefore, that the Burial Reform Association will enlarge the sphere of its inquiries.

FAT IN THE FÆCES OF DYSPEPTIC CHILDREN.

DR. W. T. TSCHERNOW of Moscow publishes in the St. Petersburg *Medicinische Wochenschrift* his analysis of the fæces of dyspeptic infants, which he found to differ both physically and chemically from the fæces of healthy infants. Dyspeptic fæces contain 85 per cent. water and 15 per cent. solids, and nitrogenous, fatty, and inorganic salts. The solids of normal fæces consist of from 25 to 30 per cent. fat, 30 to 32 per cent. albuminous matter, 10 per cent. salts, and 28 per cent. carbo-hydrates; while the solids of dyspeptic fæces contain 45 to 60 per cent. fat, and 14 to 25 per cent. albuminous matter. The carbo-hydrates do not differ very much. In dyspeptic fæces fat increases at the expense of albuminous matters. This proportion was observed alike in children at the breast and in those fed on artificial food. All dyspeptic fæces contain, as above mentioned, more fat than normal fæces, and the quantity of fat does not depend on the degree of indigestion. Dr. Tschernow concludes from these results that Demme's and Biedert's so-called "fatty diarrhœa" was simple dyspepsia.

THE WEST-END FEVER OUTBREAK.

DR. CORFIELD has made a further report on this outbreak, in which he states that he has learned that a few more households have been attacked with enteric fever, but that no prevalence of the disease now exists. He adverts to the inspection being made by Dr. Barry of the Local Government Board, but apart from referring to the infection, which simultaneously affected a number of houses, as one brought from outside, he gives no clue to his opinion as to the vehicle through which the infection was communicated. It is significant that the vestry decided to discuss the report *in camerâ*.

SEWERAGE SCHEME FOR YORK.

WE are glad to learn that the Corporation of York have applied for a loan for £101,000 for the purposes of constructing an efficient system of sewerage for the city. York has long stood in need of this both as regards the defective nature of the existing sewers, their failure to reduce the subsoil water to a proper level, and the faulty method of sewage disposal. The scheme has been announced at the public inquiry which has been held to involve a process of chemical treatment at the outfall, with a view to passing a sufficiently purified effluent direct into the river.

CONGRESS OF DERMATOLOGY AND SYPHILOGRAPHY.

AMONGST the numerous Medical Congresses which have recently been held in Paris, that on Dermatology was one of the most successful. At its last session on Aug. 10th it was resolved that the Congress should be a triennial one, the motion being supported by Dr. Unna of Hamburg, Dr. E. Schwimmer of Buda-Pesth, and Mr. Malcolm Morris

Digitized by Google

of London. A vote was also taken as to the place where this International Congress of Dermatologists should meet in 1892, when the choice fell on Vienna, for which fifty-two votes were given; London received thirty-seven votes, and Hamburg one. Another result of the meeting has been the formation of a French Dermatological Society, with M. Ricord as its President.

FOREIGN UNIVERSITY INTELLIGENCE.

Christiania.—Dr. Torup of Copenhagen has been offered and has accepted the chair of Physiology.

Halle.—Dr. Erich Harnack has been promoted to the post of Professor of Pharmacology.

Kharkoff.—Dr. Kulshiski has been appointed Extraordinary Professor of Embryology and Histology.

Kiel.—Professor Weber of Breslau has been offered the Professorship of Physics.

Montpellier.—M. Granel has been recommended by the Professorial Council for the vacant chair of Botany, and M. Imbert for that of Medical Physics.

Zurich.—Professor Lang of Jena has been offered the Professorship of Zoology.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following eminent foreign medical men are announced:—Dr. Arthur Böttcher, Professor of Pathological Anatomy in Dorpat, and formerly co-editor of the *St. Petersburger Medicinische Wochenschrift*, at the age of fifty-seven. Professor Böttcher had published many researches on the Pathology of the Liver, Kidney, and Gall-bladder, and had obtained the Baer prize of the St. Petersburg Academy of Sciences for an elaborate research on the Structure of the Labyrinth of the Ear.—Dr. P. Koch, Chief Medical Officer of the Congo Free State.

THE Government of New South Wales has appointed a committee, consisting of Sir Charles Nicholson, Bart., M.D., D.C.L., Sir James Crichton-Browne, M.D., LL.D., F.R.S., the Hon. H. N. MacLaurin, M.D., LL.D., and Sir Saul Samuel, to select designs for four large stained glass windows, which are to be placed in the Medical Hall of the University at Sydney. The windows are to contain sixteen full-length figures, and it is desired that these should represent the Fathers of Medicine and the most eminent members of the medical profession down to the present time, so that the youths of the colony entering on the study of medicine may be perpetually reminded that their science and art have had an illustrious history.

VENICE, to the great satisfaction of her population, resident and migratory, is to undergo a complete sanitary rehabilitation. The works to be commenced with this object will spread over ten years, and the first provisional estimate of the outlay amounts to some four millions and a half francs. In conjunction with this purely hygienic undertaking, a plan for remodelling the city architecturally will also be carried out, for which a period of thirty years is computed to be necessary.

CONGRESSES, for medical and surgical objects particularly, seem to multiply in Italy. On Sept. 1st will meet at Ancona the "Congresso Medico Marchigiano" (Medical Congress of the Marches), and the programme, an extensive and varied one, will occupy the remainder of the week. Other professional Congresses, also purely provincial in their objects and membership, are announced for the autumn months.

CATCHING AND "CRIMPING" FISH.

BY J. LAWRENCE-HAMILTON, M.R.C.S.

No. II.

AS compared with other vertebrates, it is stated that the relative proportion of myosin or muscle clot, one of the chief albuminoid bodies or proteids in muscle, is greater in fish than in land animals. The coagulation of the myosin causes the contraction of the muscular fibres in fish to be long retained even after death, and is supposed to give the flesh of fish transversely gashed or *crimped* a firmer and crisper taste, whilst some observers declare that the specific gravity of the muscular fibres is increased. During the post-mortem coagulation of the myosin acids are liberated and heat is evolved. Crimping is usually performed prior to death, and always previous to the subsequent cadaveric rigidity or rigor mortis. The most successful crimping is attained on capture by at once bleeding the fish whilst still alive, which bleeding immediately produces faintness, passing rapidly into insensibility. It is obvious that it is useless to resort to bleeding when blood-clotting has commenced. Except the red-fleshed, ham-like tunny, fish have generally comparatively little blood to lose. The pink colour of the salmon family is due to feeding largely on minute shell-fish, which its digestion turns red, as if boiled. The alimentary juices of the rock pouter, a kind of whiting, also convert the shells of crabs into a pink colour. In crimping, the sharp powerful blows on the head of the fish prevent the fish exhausting its muscles by convulsive efforts. When the flesh-gashing is finished, the animal is immersed in cold clean spring water. The larger and thicker the mass of flesh to be crimped, the longer the reaction of muscular contraction is delayed. Prior to crimping, after the bleeding, the fish should be gutted, and cleaned inside and out with abundant washing in fresh flowing cold water. British fishermen have an unfounded prejudice that bleeding injures crimping. Medical jurists have noticed that cadaveric rigidity occurs relatively early after severe hæmorrhage, and that from a corpse an amputated limb previously drained of all its available blood still shows post-mortem rigidity. Some physiologists consider crimping and rigor mortis to be both chiefly due to the contraction of muscular fibres caused by the coagulation of the contained myosin. Crimping fish by exposing an extended superficial surface, and that mostly deprived of its skin, to moisture, air, temperature, and bacteria, thus rapidly increases the tendency to putrefaction. Hence both the fish trades and the public would benefit by the abolition of this frivolous food-wasting fashion.

Ruining the fisheries, robbing the fishermen alike of their netted and hooked fish, the ever-hated dog-fish, on capture, without previous bleeding or gutting or being stunned, is sometimes crimped alive in writhing agony till death relieves the tortured but torturing animal of its sufferings. Where, however, there is no market for the dog-fish, then, on capture, often, its saleable liver is cut out and kept, and the mutilated fish thrown back into the sea, to die a lingering death. The dog-fish, perhaps, like its bigger brother the shark, may possibly also be kept ever hungry, ever feeding, and ever ferocious by the insatiable appetites of herds of various species of internal parasites, especially tapeworms, which cruelly torture and torment the digestions of their unwilling hosts. It is said that shoals of dog-fish will even attack and eat piecemeal the living whale.

As every schoolboy knows, live-bait fishing consists of inserting a collection of hooks through a small living fish, and then sinking it in the water. However much this sport may fascinate a professional angler, it is cruel martyrdom to the tortured little fish.

Some Kent fishermen having caught a big sturgeon, attached a rope to its tail, and thus towed their living prisoner up the Thames to sell it to an aquarium. The rope had cut its way down to the animal's backbone, who nevertheless speedily recovered in the aquarium, thus indicating, anyhow, that some kinds of fish recover from serious wounds with remarkable quickness, and even from wounds which would probably be fatal to most land animals.

In welled boats, halibuts are hung up by their tails, under the delusion that in these artificial conditions the fish will enjoy longer lives, and that their flesh will keep longer

Digitized by Google

fresh for the market. These local injuries must not be mistaken for those caused by the alleged habit of halibuts at the bottom of the sea, arranged in parallel rows, waiting and watching for small fish and shell-fish. When failing such food-supplies, the hungry halibut attacks and eats the tail of its nearest neighbour, which explains the frequently injured and absent tail of freshly-caught halibut. Hake hooked near the surface vomit on board, but if hooked at a greater depth it vomits before reaching the surface. Pursued by bigger fishes, the smaller fish will sometimes vomit the contents of their stomachs, partly through fear, partly to lighten their load, so as to be able by quicker swimming to escape, but perhaps, also, like the sea-gull chased by the skua, or dung-bird, so as to appease the not over-fastidious appetite of its pursuer, who thus gets partly digested or naturally cooked food. Many of the sea-cucumbers (Holothuriæ) on injury or irritation eject part or all of their internal organs. Some fish disgorge for the pleasure of again eating their vomited food. Crabs attacked by sea-birds shed their claws and legs in succession. It is stated that sometimes hooked fish get their skins inflated by accumulated air between the skin and subjacent muscles, and that such fish rise to the surface unable to sink. A fish hooked in deep water and quickly drawn up to the surface is like an animal hunted up-hill to death, or like a man rushed up in a balloon, and hence the suddenly diminished pressure, to which fright and pain are added, frequently brings up such fish dead at the surface of the water. Frank Buckland stated that he believed that a fish held by a hook in a very rapid stream would be drowned by the rushing water holding it like a vice on each side, and thus not allowing the gill covers to expand.

A fish is said to drown in the air like a man drowns in the water or is strangled in the air. In each case the air is prevented from getting to the breathing apparatus. In man, because, in drowning, the water intervenes, though perhaps also to spasm of the glottis acting as a sphincter. Experiments by Sir Benjamin Brodie and Dr. Goodwyn with coloured fluids and quicksilver showed that in animals drowned under observation the small amount of fluid entering the lungs was not sufficient to account for death. In man also death by drowning may arise from exhaustion, shock, apoplexy, disease of the heart, concussion, injuries, or from mixed causes. The gorging with water of even the minute vessels of the lungs in certain cases of drowning may be chiefly due to post-mortem changes. In fish, the numerous minute bloodvessels composing the gills or fish lungs, rapidly drying, stick together and get choked up. Hence the familiar violent open-mouthed gasping of fish when landed. In the air, the fish strives in vain to separate its gill filaments, which it cannot do without the intervention of water. (There are exceptional families of fish which can breathe in air for long periods together.) Anglers often drown fish in the water. The moment the fish is hooked, it rushes about in frantic fright, rapidly running through the successive stages of undue energy, exercise, exertion, and exhaustion. The faster and more furious the fish fights or struggles, the faster it breathes and overworks its heart, till it is fully pumped out of breath, when the knowing sportsman pulls the captive fish's head to the surface of the sea or stream, "between wind and water," and finally, raising the fish's mouth out of the water, the exhausted animal becomes more and more faint, feeble, and giddy. Its gills adhere together, and virtually cease acting. The blood becomes over-carbonised, and hence the fish drowns or suffocates whilst still in the water.

It is said that at 100 fathoms, or 600 yards, the pressure of the sea water exceeds 265 lb. to the square inch, and hence securely corked empty glass bottles sunk by means of weights below 100 fathoms become crushed. If filled with water, the cork is driven inwards, and in drawing up the bottle to the surface, the cork is often found returned in an inverted position to the neck of the bottle. As a practical rough-and-ready approximation, it is estimated that for every 1000 fathoms, or 18,000 feet, the pressure may be considered as about one ton to the square inch. To haul up one of the deep-sea lines used in the *Challenger* deep sea dredging, it took the fishermen from twenty to thirty minutes; and to avoid such hooked fish being blown to pieces, and leaving only a small shred of their individual anatomy attached to the hook, these abyssal fishes must be withdrawn very slowly and gradually. Raised from these colossal depths, the diminished pressure distends the gases inside the fish, especially should it be provided with an air bladder, and causes the fish to get to the surface (if not dead, almost powerless) in a rigid cataleptic spasm, usually with its stomach inverted and inserted into or through its mouth. Its eyes are started and stalked from their natural sockets, protruding outwards like horns. Frequently such fish, each weighing from 25 lb. to 50 lb., on approaching the surface, will be shot out of the water at some distance beyond the boat, because the animal is sent upwards by the expansion of its contained gases, quicker even than the experienced deep-sea fisherman can haul in his prize.

In trawling, owing to the pressure of the net and its contents, fish, especially herrings, are often hauled dead into the fisherman's boat. Strangled and drowned in the meshes of the net in water, herrings putrefy even too rapidly to be serviceable to the professional fish-curer, who frequently cures fish which in their so-called "fresh" condition would be unsaleable and uneatable. It is said that if an elastic band be placed round the gill-covers of a fish in an aquarium it makes violent efforts to escape this strangling. It moves rapidly in hurried fear and excitement in its tank, and will at times attempt to leap out of the water. It soon dies with the rapid invasion of cadaveric rigidity and early putrefaction. Now, the herring strangled in the mesh of the fish-net is also much pressed upon and banged about, handled more or less with dirty hands, all being extra conditions to aid, advance, and accelerate rapid decomposition. If, before capture, the herring should have over-distended its stomach and intestines with undigested food, then putrefaction sets up so rapidly that such herrings are even useless to the fish-curers, who technically term this condition "gut-pock." Some American and Swedish fishermen, after an abundant catch of herrings, whose insides are over-distended with recent undigested food, pen up the herrings alive in the nets sunk in the water, to give the animals time to digest their food, and thus avoid the loss of the herrings from the invasion of subsequent "gut-pock," which I trust later to treat of purely from biochemical and microscopic researches.

Some twenty-four hours after capture, notoriously unbled and ungutted herrings are peculiarly prone to post-mortem spontaneous pouring out or extravasation of blood, which darkened, damaged, and bruised appearance is quaintly recognised in fish-trade slang as "over-day tarts." Medical jurists have pointed out that in drowned persons putrefaction usually begins about the head, whilst the rest of the body may remain normal. Post-mortem spontaneous bleeding is probably due to the softening of the vessels from early and incipient putrefaction, to the influence of gravity, and to the irregular post-mortem stagnation of blood in the capillaries (apparently some of the colouring matters and extractives pass into and remain in the tissues also as a putrefactive change). The process of the coagulation of the blood intensifies the appearance of these post-mortem effusions or extravasations. Possibly the cadaveric rigidity affecting the heart and the coats of the arteries prior to the post-mortem rigidity of the voluntary muscles forces blood into the venous capillaries, where it unequally stagnates, simulating the appearance of recent bruises during life. (In some fish the heart be at forcibly long after all other signs of life are apparently extinct. A frog's heart separated may be kept pulsating in certain nutrient solutions. A freshly decapitated eel's head will bite. Dead mackerel are said even to "turn somersaults" owing to excessive sudden rigor mortis. The post-mortem quivering of some snakes explains the popular belief that snakes never die till sunset.) On death the skin loses all its previous elasticity. Medical jurists lay special stress upon the fact that this cadaveric lividity is chiefly seen in those dying suddenly in full health or by a violent death (as hanging, drowning, strangling, apoplexy, &c.), and is but very rarely seen in those who have died of hæmorrhage—another proof why fish should be bled on capture. If a stout muscular person has died suddenly, and the body is then wrapped up closely and tightly in a sheet and allowed thus to cool, then post-mortem bleeding may make a zebra-like series of stripes or bands, suggesting recent flogging during life, from which it is distinguishable by the fact of the skin being unbroken. Now, the above phenomena happen to herrings drowned in the meshes of nets, who suffer squeezing and squashing both from the contents of the nets and from the heavy weights of their thoughtless

Digitized by Google

captors. In the herring the chief post-mortem bleeding takes place first about its head, gills, gill-covers, and fins, and a little later internally along and around its backbone or spinal column. In the skate its mucous secretion continues for a time, apparently, after its death.

In fish, as in man, all contused or incised wounds and bruises during life, as well as post-mortem spontaneous bleedings, rapidly pass into early putrefaction. In fish these decompositions take place with much greater rapidity and energy, which natural putrefactive processes are terribly increased and accelerated by ignorant, wasteful, and unnecessary exposure to abundant air, moisture, heat, sun, rain, pressure, banging, bruising, wrenching, twisting, hammering, packing, and handling; to many varieties of solid, liquid, and bacterial filth, and to melted or melting ice. The consideration of these fish-spoiling combinations, wastefully sanctioned by chronic conventional custom, and the general indifference and apathy of the public and the medical profession to fresh fish preservation, I propose to treat of in my next contribution to THE LANCET, which has from the earliest traditions of its history always opened its columns for the discussion of all matters connected with a cheap, abundant, and healthy food-supply for the people.

THE IRISH PRISONS BOARD REPORT.

THE report made by the General Prisons Board of Ireland to the Lord-Lieutenant upon the operations under their supervision during the past year brings to light the welcome fact that in the sister island, as in Great Britain, the statistics of the past few years show a steady and marked reduction in the numbers of the convict population. In the short period of seven years past this reduction has amounted in the case of male convicts to 41 per cent., and in the case of females to 56 per cent. So pronounced an improvement has enabled the Board to recommend that the work of enlarging the convict prisons of Ireland should not at present be proceeded with, although a Royal Commission which sat only so lately as 1884 recommended a very considerable outlay of public money with that object. The Board, in discussing the question afresh, remark that a most material change of circumstances has ensued since that date, which was then probably not foreseen, and adduce the above figures in support of this view. The fact is certainly very remarkable, and, fitting in as it does with our own experience on this side of St. George's Channel, affords ground for a most encouraging hope that we are coming to a time of "sweeter manners, purer laws."

In another branch of their labours the Prisons Board have met, however, with less gratifying results. The number of commitments to prison for small offences shows, as compared with the preceding year, a very considerable increase, and this increase is largely made up, as we gather, of commitments for drunkenness. This one offence accounts, indeed, for nearly one-half of the total number of such imprisonments, and we have it on the authority of the Board that the criminal records show this great social evil to be extending.

One very important point in the theory of punishment is strikingly illustrated in the present report—that, namely, of the effect of short sentences upon habitual offenders. The remarks of the lady superintendent of the Grangegorman Prison upon this subject merit careful attention. She says: "I beg respectfully to inform you that the number of prisoners committed to this prison for the past year was excessively high, being over 8000, and to draw your attention to the fact that this number includes a great many old offenders, who were recommitted several times through the year, and generally for such short sentences as to deprive the imprisonment of the deterrent effect that longer ones might exercise. ..... I may refer to one (case), L. K——. This woman was committed to this prison thirty-four times last year, and never received a sentence for a longer term than fourteen days." A footnote adds that this particular offender had been committed 146 times in previous years, so that she has suffered 180 imprisonments in all. In such a case it is ridiculous to attempt to turn the offender into better courses by ordinary means. Our correctional appliances will continue to be absolutely helpless in a case like this until it is clearly recognised that persons of this class are not capable of regulating their own conduct. An asylum, not necessarily a lunatic asylum, but a place where they could be subjected to the exact amount of restraint necessary to keep them out of mischief, is the right place for such people. The confinement of the Bridewell is probably unnecessarily severe while it lasts, and it has the fatal defect of being intermittent. Not severity, but continuous care, is the remedy for such mental and moral disorder as this wretched creature exhibits.

MEDICAL OFFICERS OF THE ARMY AND NAVY.

THE report of the Committee of Inquiry into the pay, status, and conditions of service of medical officers of the Army and Navy has now been presented to both Houses of Parliament. Dealing first with the Army, the Committee consider the question of full pay, the rates of which were settled by the Royal Warrant of 1879, and the conclusion come to is that there is nothing to show that the pay is extravagant. The evidence received leaves it doubtful whether, if lower rates were offered, the same class of medical officers would be obtained. Careful inquiry has been made from those persons considered most likely to be able to suggest reductions, but without any success. As to retirement, it is pointed out that the large number of retired officers is owing to two causes: first, the compulsory age of retirement—namely, sixty for surgeons-general and deputy surgeons-general, and fifty-five for the executive ranks; and, secondly, to the right which every medical officer has to retire after twenty years' service. The Committee do not see their way to propose any alteration in the age for compulsory retirement in the case of the executive ranks; but, with reference to administrative officers, they see no reason why the surgeons-general should not continue to serve up to the age of sixty-two. No interference with the right to retire after twenty years' service is suggested, but the Committee are of opinion that, without altering the conditions of retirement or the rates of retired pay, more service might fairly be required from medical officers. It is believed that the financial saving must be chiefly effected by limiting as much as possible the establishment of officers, and it is recommended that at small home stations, where there is not more than two or three hours' ordinary daily work for the medical officer in charge, civil practitioners should, where practicable, be employed. Passing to the question of rank and title, the Committee point out that medical officers of the Army, especially the younger officers, are not contented with their present position, relative rank, which they contend was the only rank they ever held, having disappeared. The grievance of medical officers of the Army on this score appears to the Committee to have originated in great part from the abolition of the regimental system. On this question the conclusion of the Committee is as follows:—"We are of opinion that, in the Queen's Regulations and Army Pay Warrant, it should be stated that the officers of the Army Medical Department shall hold the following military ranks with relative army ranks, a table of which we append. We recommend that relative army rank, the abolition or omission of which has immediately caused the present discontent, should be restored in the following manner:—

Present Title—Medical Staff.	*Proposed Rank and Title—Royal Medical Staff.*	*Relative Army Rank.*
Surgeon-General ..	Surgeon-General ..	Major-General
Deputy Surg.-General	Surgeon-Colonel ..	Colonel
Brigade Surgeons, and Surgeons-Major now ranking as Lieutenant-Colonels	Surgeon Lieutenant-Colonel	Lieutenant-Colonel
Surgeon-Major	Surgeon-Major	Major
Surgeon	Surgeon-Captain. This rank to be given after three years' service as Surgeon-Lieutenant	Captain
Surgeon	Surgeon-Lieutenant	Lieutenant

The recommendation made with regard to service is that a plan should be devised whereby medical officers of the Army should not be changed from one duty to another as fre-

Digitized by Google

quently as at present, and the Committee are of opinion that it would be an advantage to all concerned if, without reverting to the regimental system, a medical officer were on first appointment attached for a definite term to a regiment or other administrative unit. When medical officers are on leave in consequence of disease contracted in and by the service, the Committee consider that they ought to be entitled to the same privileges as combatant officers. With regard to foreign service, it is suggested that the term of continuous service abroad should not exceed five years, except in cases of emergency, while the employment of retired officers is strongly deprecated, excepting perhaps as a temporary measure; and with regard to service in India, the Committee pronounce it advisable that, so far as is practicable, the regulations which obtain as regards pay and allowances at home should extend to officers serving in India. On the question of admission into the service, the Committee believe that a certain number of desirable officers might be obtained by exercising the power already possessed by the Secretary of State of offering a certain number of vacancies to men who have filled the office of house-surgeon or physician at hospitals, without examination, and they also recommend that the commissions of medical officers entering the Army shall date from the time they enter the service and not, as at present, from the time they leave Netley. One other point is dealt with under this head—namely, the sufficiency of the diploma of the Society of Apothecaries, and the result arrived at is that there is no good reason for requiring candidates at the entry examination to produce a second diploma besides that of that Society, if obtained under the conditions of the Medical Act of 1886. The report on the subject of Army medical officers concludes with a strong condemnation of the short service proposal.

The Royal Navy forms the subject of the second part of the report. The Committee express their pleasure at finding the medical service of the Royal Navy in a satisfactory and contented condition. Relative rank which regulates the position of medical officers of the Navy is well understood, and the officers appear satisfied in all respects with their pay and position. With regard to service, it is recommended that inspectors of hospitals and fleets should not be compulsorily retired before the age of sixty-two, and that naval officers should have opportunities from time to time of improving themselves by professional and scientific study. As regards the period of voluntary retirement, now twenty years' service afloat, the Committee do not recommend any alteration; but as regards retirement on gratuity after eight and twelve years' service, they declare that there has at present been no opportunity of judging how the scheme will affect the retired list, and that therefore they are not in a position to recommend any alteration.

Some members of the Committee dissent from certain of the recommendations contained in the report.

THE PARIS UNIVERSAL EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT.)

The International Congress of Forensic Medicine.—Railway Brain.—Hanging.—Rape on Children.—The Confinement of the Insane.—Morphiomania.—Simulation of Disease.—Wet-nurses and Syphilis.

FOLLOWING immediately the Congress on Criminal Anthropology came the Congress on Forensic Medicine. Though the attendance was small, the debates were well conducted and to the point. In this respect the Congress on Forensic Medicine was very superior to the Congress on Hygiene. The former had but a hundred members or thereabouts, while the latter had close upon seven hundred; but the members of the one Congress were all well versed in the subject, while the large majority of the members of the Hygiene Congress really knew very little about hygiene; they were learners rather than teachers. The Congress on Forensic Medicine was composed of medical men who have been witnesses or experts in criminal and other legal proceedings, and with them sat several celebrated barristers, magistrates, and judges. Thus every delegate had actually practised forensic medicine or dealt with it in one way or other, while many members of the Hygiene Congress had never attempted to practically enforce any rule of hygiene.

The Congress of Forensic Medicine was opened on the 19th inst., in the afternoon. Dr. Brouardel, as Dean of the Faculty of Medicine, was in the chair, and the sittings were held in the grand amphitheatre. He was seconded by Dr. Vleminckx, delegate of the Belgian Society of Legal Medicine, together with its secretary, Dr. Moreau. The University and the Bar of Brussels were represented, and also the New York Society of Forensic Medicine. There were also delegates from Brazil, Denmark, Hawaii, Italy, Mexico, Monaco, Paraguay, Peru, Roumania, and Switzerland. Dr. Brouardel, after a few graceful words of welcome, called upon Drs. Vibert and Gilles de la Tourette to read their papers on the Relation between Forensic Medicine and Cerebral Traumatism. Dr. Vibert insisted that the symptoms were not at once apparent. After a railway accident a man may very calmly walk to the next station, take a cab, do all that is necessary under the circumstances, and yet be perfectly unconscious. The injury to the brain where there is no outward sign, but which results from a violent shock, gives rise to considerable legal difficulties when railway companies and others are sued for damages. This is all the more complicated, as the symptoms do not always manifest themselves till a considerable time after the accident, and there is, further, a danger of the patient shamming what he does not feel, in the hope of getting heavy compensation. Again, it sometimes happens that a very severe injury is followed by slight consequences; while on other occasions a trifling traumatism is followed by general paralysis and insanity. Does hereditary predisposition account for this difference? In many instances no such evidence has been forthcoming, and, supposing it to be produced, ought it to lessen the claim for damages? The symptoms—sadness, loss of memory, &c.—are often attributed to a hysterical disposition; but how is it, for instance, that an old soldier, who had been through the hardships of a campaign and had never shown any such hysterical tendency, nevertheless displays the same symptoms after a railway accident? This is evidently due to a mechanical accident, and not to a predisposition. It is objected that women rarely suffer from "railway brain"; but women are not so often exposed to railway accidents. Dr. Gilles de la Tourette thought that traumatic patients invariably sought to hide their antecedents. Prof. Charcot had, on the contrary, often found hysterical antecedents with patients suffering from "railway brain." The expert called in by a railway company sees the patient two or three times; Professor Charcot keeps his patients for months, sometimes for years. The majority of cases are male patients, because the accidents occur to engine-drivers, stokers, &c., and the absence of hysterical predisposition cannot therefore be used as an argument. Dr. Lacassagne defined traumatisms as due to the organic injury resulting from a shock, whether caused by a railway collision, a fall from a scaffold, or a carriage accident. He had noticed, especially among workmen, men of great activity and industry, that after such an accident they became completely idle, and that with this idleness was manifested an enormous increase of appetite. Some friend takes the patient in charge, and promises to secure him liberal compensation. The man thereupon no longer dares to move, for fear of losing his compensation, for he feels that he is always being watched. But when once the verdict is given, the matter legally settled, these patients contrive to recover in an extraordinary manner. Dr. Motot protested that there were slight as well as serious cases. Another delegate considered it was a very great hardship that military pensions were not allowed unless the claim was accompanied by a statement that there was no predisposition; therefore this predisposition is carefully concealed. Sometimes also compensation or pensions were refused on the ground that traumatic hysteria is reputed to be curable. Pensions were refused even when it was demonstrated that the patient enjoyed the most perfect health before the accident, if it could be shown that there was predisposition. Dr. Penard urged that experts should be very reserved and moderate. The judges were always impatient for an immediate conclusion; medical men must, nevertheless, insist on having plenty of time for their observations. Dr. Brouardel thought that the word "hysteria" should be excluded from the discussion. The worst was that different doctors see the patient in different periods of the disease and of the judicial inquiry. Alluding to the symptoms described by Dr. Lacassagne, he said the same had been noticed among prisoners. Their dulness and silence were often due to

Digitized by Google

change from active to idle life, combined with a change of diet. This caused troubles of nutrition, which produced a form of intoxication. The patient, practically, was poisoned, and got better again when he returned to more active life and to his normal diet. The predisposition to hysteria was an absurd excuse, enabling railway and other companies to escape from their just liabilities. Everyone was slightly predisposed to hysteria. Compensation was refused the other day because the sister of the victim had a little hysteria at a moment of great trouble, when divorced from her husband. Hysteria ought to be set aside. No one could say that there had never been hysteria in his family, and therefore everyone was liable to find his claims for compensation denied. M. Chaudet said that the companies very often negotiated with the individual and came to a private agreement, giving him or her a small sum. Then, in the course of time, the injury proved much more serious than had at first been anticipated. The case was consequently brought forward again, and an action entered, this time before the civil tribunals, where it takes a very long time to obtain a decision. It was urged that there ought to be some method in the legal proceedings by which a verdict could be altered if, in course of time, the injury proved altogether different in its effects from what had been anticipated.

The Congress then adjourned, and on Tuesday morning commenced a discussion on the question of Hanging. Dr. Gosse, of Geneva, described the experiments he had made on himself. On two occasions he had succeeded in so far hanging himself that he entirely lost consciousness. He found that the cord often did not squeeze the throat so as to stop the breathing. The rope formed a sort of triangle which pressed on the carotid but not on the larynx. In that case death was not painful, there was a buzzing sound in the head and unconsciousness at a very early stage. But if the rope pressed on the throat then the struggle for breath was very painful. On carefully examining criminals after hanging, it would be found that when convulsions occurred the lungs were empty. If the victim could fill his lungs with air before the rope tightened he would not suffer so much, if at all. When a person was found hanged and there were two marks showing that the rope had changed place, this might be considered as a suspicious sign. It, in all probability, meant that he had been hanged after having been strangled. This he had noticed in the case of a gendarme hanged on the Swiss frontier. There were two marks, so he made a more careful investigation, and then perceived that the rope was too short for the gendarme to have been able to hang himself. Ultimately what seemed a suicide was proved to be a murder.

Dr. Lacassagne was now called upon to read his interesting paper on the Detection of Rape on Little Girls. Assault on little girls constituted about a third of the total number of cases brought before the Assizes Court. In his opinion, a regulated method of proceeding should be prescribed for such investigations. This was not so necessary in great towns, but rather for small villages and rural centres where the local practitioners had but slight experience of such matters. They did once in ten years what to others was a matter of weekly occurrence. Medical and legal rules for the examination of the victims of such assaults should be drawn up. This would seem irksome to very able and experienced men, but the generality would benefit by the uniformity of the observations, and after the prescribed formula of questions had been filled up with the required answers, it would be always optional to add any further and special observations thought useful. The first thing was not to delay the examination of the victim. He did not fully understand all the exigencies of legal forms, but magistrates, on their side, were evidently not specially instructed in anatomy &c., otherwise they would not so often be the cause of delays. The second point on which he wished to insist was the necessity of the presence of a third person—the mother of the child, a relative, or, if no one else could be obtained, the policeman who had brought forward the case. Thirdly, it was indispensable to question the child—to let her tell her story. It was not necessary to believe the child's story, but it very often gave a clue to the truth. Children frequently had altogether false ideas as to what constituted an assault. Dr. Moreau of Charleroi suggested that very careful questions should be put as to the dirty habits of the child and her companions. It was surprising how vicious, how skilful and learned in vice, these little children proved to be. In his opinion, the presence of the mother or the magistrate during the examination would overawe the child; but the expert, if alone, by patience and kindness would very often obtain precious information. With regard to redness and other local signs, he thought that not only a second but very often a third examination was required. The man should be examined and his daily occupation ascertained, for it was proved that certain trades produce a greater proportion of crime of this description. In Belgium, for instance, a very large number of assaults on young girls were perpetrated by bootmakers. Also a great number of persons still believed they could cure gonorrhœa by coming in contact with a virgin, and this superstition often led to the detection of the criminal. Dr. Lacassagne closed the discussion by replying to several arguments adduced. There was a very great danger of extortion, and if the doctor did not have a witness with him he might certainly find himself accused. He had the right of self-defence, and the only effective defence was to have a witness in the room. Many of the children were thoroughly corrupt and vicious, and were seeking to obtain money by exaggerated or false accusations, and it would be more profitable to accuse the doctor than some workman or labourer living in their neighbourhood. Therefore, even if it rendered the inquiry more difficult, still he insisted on the presence of a witness.

At the afternoon sitting, Dr. Motet, secretary-general of the Congress, read a paper on the Removal and Confinement of the Insane. He dwelt at length on the difficulty due to the various degrees of imbecility. One, having lived the ordinary life of a healthy child, is seized at the age of puberty with desires which he seeks to satisfy in a brutal manner: there can be no doubt as to this case. Another in appearance is less brutal; he is less impulsive, but equally the victim of hereditary transmission: he will be treated differently, though his complaint is the same, his irresponsibility equal. Then, again, a person who is in a state of acute mania, who is violent, is often more easily cured than the quiet patient, who answers, on the whole, very reasonably to the questions put to him. The magistrate, in the face of such difficulties, is sorely puzzled. He calls experts to assist him. Dr. Motet insisted on the necessity of an independent medico-legal examination before any verdict was pronounced that in any way interfered with the freedom of the subject. This opinion was endorsed by the Congress.

Drs. Lutaud and Descoust presented a report on the Legal Questions arising from the Abuse of Morphia. Most practitioners had had opportunities of noting that the taking of morphia had become much more general during the last ten years. At first administered under the personal surveillance of the doctor, the patient too frequently learnt how to inject the drug without assistance. This was admissible for incurable and extremely painful diseases, such as cancer; but it was too often done on the smallest pretext. The question arose as to how morphiomaniacs procured the morphine. Of recent years there had been some severe sentences pronounced against dispensing chemists for illegally selling the drug in Paris and other parts of France. A very respectable chemist related to the reporter that he now sold in the course of the year only about eight pounds' worth of morphia, while formerly his sale amounted to about £40, yet his business in other respects had in no wise decreased. Dr. Brouardel had recently found in the house of a very fashionable lady a bottle containing no less than 200 grammes of morphine, and it was now ascertained that a great number of morphiomaniacs had found means of procuring the drug from wholesale druggists and commission agents. This was to them a triple advantage; they escaped the surveillance of the doctor, they could obtain unlimited quantities, and it cost them much less. The only legal restriction imposed on wholesale druggists was that of inscribing in their books the address of the person with whom the sale was effected. Other morphiomaniacs drew up prescriptions and signed them with the name of a doctor. This was, of course, illegal and could be punished, but would be avoided if doctors would draw up their prescriptions on paper with a printed heading, and sign their names more legibly. It was also urged that in his prescription the doctor should distinctly state how often the prescription was to be renewed. Dr. Motet urged that cocaine was even more dangerous. Dr. Brouardel confirmed this opinion. Cocaine was three times more rapid in its effect, and had the peculiarity of making the people who took it jump out of the window—a double danger, for it not only killed the victim of the drug, but might possibly kill some innocent

Digitized by Google

pedestrian passing under the window at the time. Dr. Brouardel informed the Congress that a new project of law affecting dispensing chemists was now in course of preparation. It was proposed to draw up a list of drugs that could not be renewed without a fresh prescription from the doctor. There would be also a permanent revision committee, with power to alter this list. In the northern provinces of France it was becoming quite the fashion to give evening parties where the principal diversion was the administration of subcutaneous injections of morphia to the guests. Several speakers raised objections to a law preventing the renewal of an old prescription; this would be especially awkward for persons who were travelling. Finally, the Congress adopted the following resolutions: "Druggists and manufacturers of chemical or pharmaceutical products must not sell morphine or cocaine to others than dispensing chemists, and must only deliver these poisonous substances at the chemists' houses. A dispensing chemist must only make up a prescription once if it contain either of these two substances."

At the sitting held on Wednesday morning, Dr. C. Moreau of Charleroi, secretary-general of the Belgian Society of Legal Medicine, read a paper on the Simulation of Disease. One of the difficulties arose from the fact that the books on this subject instructed not only the doctors, but also the individuals who practised methods of deception. He thought the Congress should constitute an international committee to collect information as to the methods of detection that had been employed with advantage in different parts of the world. Dr. Vibert argued that, because a person shams with respect to one symptom, this did not prove that all the symptoms were fictitious. It was necessary to inquire what were the antecedents of the patient, and to see if there were not hysterical accidents. In the course of a desultory conversation, it was objected that a person who was really of unsound mind, or who was perfectly sincere in denying the authorship of some crime, might, in his desire to effect an escape, resort to some form of simulation, and might sham even in a ridiculous manner. A Belgian delegate gave the history of a case which, in Belgium, had caused a great sensation. A man was deserted by his wife, and he ultimately found that she was serving as a cook in a house of ill-fame. The husband approached her through a backyard and handed her a letter ordering her to come home, but she refused to do so. He thereupon drew his revolver and fired twice at her. The woman fled for her life. Another woman entered the kitchen to see what was the matter. The husband, though he had never seen this woman in his life before, and had nothing whatsoever against her, levelled his pistol, followed her movements, fired twice, and wounded her badly. Then the unfortunate man, acting as if in a dream, turned the barrel against himself, and again fired twice. This man, when arrested, frankly and without hesitation stated that he had shot at his wife, that he did so with deliberation, and had armed himself expressly for the purpose of shooting her if she refused to leave the house of ill-fame. But he utterly denied having shot at any other woman or having shot at himself. After discharging his weapon at his wife his mind became a blank, and he evidently had no sort of recollection of what happened subsequently. Dr. Vibert, on the strength of this story, inquired whether, in a great crisis and under the stress of great mental agony, anæsthesia does not often occur—a sort of mental trance which allows the automatic accomplishment of daily occupations without the patient having any knowledge or any consciousness of what he is doing. Dr. Duponchel complained that there were many errors in books treating the question of simulation. He related the case of a woman, who complained of such fearful pains in her left breast that it was amputated; but nothing was found. Shortly afterwards there were equal pains in the right breast, and this was amputated and also found to be perfectly healthy. It was only when the woman asked to have her wrist cut off that the possibility of her shamming occurred to the medical attendants. With regard to men, Charcot had largely contributed to show that what used to be attributed to simulation was in reality due to hysteria. Old authors, by their written works, proved how often they were mistaken. He related the case of a soldier who was repeatedly punished because, when at drill, he had cramps in the legs just at the moment he was ordered to march. This afterwards proved to be a genuine form of illness. Before attempting to detect simulation it was better to seek to discover real disease. People only imitated well what they had actually felt. The real means for detecting sham illness was to perfect the methods for discovering real illness. Was it possible now to sham heart disease or lung disease? When nervous diseases were better known they would be more easily detected. Some years ago a recruit feigned an attack of rabies, and the whole of the revising council drew their swords in self-protection. Nowadays this would be impossible. The first measure was isolation; a person who was shamming would hold out before witnesses, but he soon became wearied of the *rôle* when alone. Then the person should be examined very often and thoroughly fatigued. Dr. Duponchel did not advocate using cunning stratagems to make the patient contradict himself. The doctor had but a few moments to give to the case; the patient had all the twenty-four hours to think over it, and would very often turn the tables against the doctor. This was humiliating, and, if it happened in a dormitory before other patients, might have a very disastrous effect on the discipline of the establishment. It was necessary to be very sceptical, and not to believe even when a man confessed that he was shamming. This occurred in a Paris hospital recently. A man had a fit every Tuesday evening at 6.30 P.M. punctually, and never on any other occasion. Of course, he was suspected of simulation. One day, wearied possibly with his hospital life, he declared the whole thing was a sham. The director had the patient brought to his office and invited him, as he was only shamming, to simulate once again, and immediately, the attack. This the patient attempted to do, and so completely failed that the witnesses present were convinced his attacks were not simulation, though in the earlier stages they might have been an exaggeration of his malady. He was glad to note that simulation to escape military service was very much on the decrease in France. It existed only in the provinces. Every Parisian was thoroughly imbued with the sentiment that he owed his services to the mother country, and the attempt to avoid the military conscription by simulating disease, which was so frequent under the Empire, was unknown under the Republic. The Congress loudly cheered this assertion—an assertion, by the way, which was confirmed by several other speakers. Dr. Duponchel urged, on the contrary, that it would be very bad policy to doubt the word of a soldier who complained of illness; that it would be a source of great weakness, in action, to send ailing to the front. Dr. Lacassague suggested that one of the most effective methods of detection was to ask the patient to write something—his memoirs, his impressions, or a letter. This often disclosed more than mere conversation. As the doctor could not be with the patient all day, there was a great advantage in securing the assistance, as observers, of his guardians, or even his fellow-patients. One individual who was pretending to be insane, the better to prove his insanity, struck the speaker a very heavy blow. What was to be done in such cases? Where insanity existed or was feigned, the case could best be treated and watched in an asylum. The doctor must be very slow in his inquiry. He must not allow the patient to do everything he desires; a little restraint, a little discomfort, must be imposed; perhaps then the simulation would be abandoned. Dr. Motet proposed that in prisons there should be a special ward or section for the cure and observation of those who were supposed to be simulating disease, especially madness. A Belgian delegate thought that criminals who feigned to be mad should be taken to a madhouse, and then told they had been acquitted. After this, if the culprit were shamming, he would very soon show symptoms of recovery. Several members of the Congress rose and spoke against the practice of such deception, and thought that the mere transmission to an asylum without resorting to falsehood would often produce the desired effect. The discussion terminated by a general understanding that it would be well, when practical, to have prison asylums.

At the afternoon sitting, Dr. Morel-Lavallée presented a very important report on Syphilis among Wet-nurses. As the employment of wet-nurses is, fortunately, not so general in England as in France, the question is of more interest on the French side of the Channel; nevertheless, it is a very grave matter, and merits all the more careful attention as it is fraught with many complications. Medical men might and should in a large measure prevent the spread of syphilis by nurses. According to French law (Article 1382 of the Civil Code), a doctor may be sued for damages caused by his imprudence, and, according to the verdict of the Dijon Court on May 14th, 1868, because of his

Digitized by Google

reticence. On the other hand, by the Article 378 of the Penal Code, the doctor is bound to respect professional secrecy. But, if the law is thus contradictory, his moral obligation is clear enough. The doctor's duty is evidently to prevent the spread of a contagious disease which is one of the most terrible scourges of humanity. The question presents itself under many different points of view. For instance, if the nurse is still healthy but the infant is discovered to be syphilitic, it is the duty of the doctor to prevent the nurse suckling the child, however great may be the inconvenience and loud the protest of the parents. Even if the nurse consents at her own risk to continue nursing the child, it would be necessary to draw up a legal document to that effect, countersigned by the nurse's husband, and no lawyer would consent to draw up such an act. Consequently, if the nurse falls ill, she will always be able to sue the parents of the child, and the doctor's responsibility and reputation will be involved. The doctor must therefore at once order the removal of the child. But, in doing this, the doctor must not mention the word syphilis to the nurse, for this would be a breach of the professional secrecy he owes to the parents, and would expose them to scandal-mongering, and perhaps even attempts at extortion from the nurse or others. Then, again, there is this other difficulty—that the nurse should not be sent away, for she may be in the period of the incubation of syphilis. The nurse should therefore be retained for six weeks or so, and render what service she can as a dry-nurse. The parents, however, may refuse to allow the separation of the child and nurse, but may allow the nurse to seek employment elsewhere. Then the doctor, as a last resort, must withdraw from the case, sending final instructions by registered letter, and keeping a duplicate of the same, so as to cover his responsibility. Sometimes, the infant having inherited syphilis, the wet-nurse is already contaminated before the mischief is noticed. It is then best to persuade the parents to confess the case to the nurse, to give her as handsome a compensation as they can afford, and get her to continue suckling the child. Discussing this portion of the report first, Dr. Brouardel thought that the only way to protect the nurses was to intimidate the father of the family. The saving point is that the milk of syphilitic nurses does not injure syphilitic children. At the hospitals it was easy enough to find syphilitic mothers who would gladly go out as nurses. Therefore, in view of preventing a nurse receiving the charge of a child likely to have inherited syphilis, the Congress passed the following resolution: "It is better that the child should be suckled by its mother; the consent of the father will frequently be obtained if he is made clearly to understand that the mother has nothing to fear from the infant; for if the infant is syphilitic, the mother will, in all probability, have been already contaminated before the accouchement." Some discussion followed with regard to the question of professional secrecy where abandoned children are concerned, it being argued that the State should be as jealous of the reputation of the child as its own parents. It was ultimately decided that the doctor should confidently entrust to the Director of the Public Assistance information concerning syphilitic lying-in cases, so that arrangements should be made to keep syphilitic infants and mothers together. Another question was put: A wet-nurse comes to consult a doctor. He finds that she is apparently in good health, but she has an infant in her arms who is syphilitic. If she says she is only nursing the child, the doctor has no right to examine the child or pronounce an opinion on its condition of health without the sanction of the child's parents. If the nurse, knowing this and wishing to obtain the doctor's opinion, tells a falsehood by pretending that it is her own child, then the doctor will tell her to continue suckling the child, on the ground that no further harm can be done. In that case the nurse will be the victim of her own falsehood; but still it would be more satisfactory if the spread of the disease could be stopped. Several speakers argued that the doctor only owed professional secrecy towards the person who came to consult him; and, if a nurse brought a child, he was justified in saying that the disease was syphilis. Another supposition arises. A nurse has suckled a syphilitic child, or a child suspected of syphilis; the parents refuse to keep this nurse. Is she to return to her home and perhaps infect her own family, or is she to try to get a place as wet-nurse elsewhere and there infect the second child entrusted to her care? She is in the period of incubation. No one can suspect the danger except the doctor of the family she has left, and his hands are tied by the bonds of professional secrecy. Again, if a chancre appears on the breast of a nurse some days after she has been suckling an infant, what shall be done? First remove the child, and if in five or six weeks there are no symptoms the child will have escaped contagion, and can then be given over to a healthy nurse. Till that time it must be fed from the bottle or from a goat. If the child shows, however, symptoms of syphilis, then it can be fed like all syphilitic children, and can be given back to its first nurse. In view of this probability, it would be well to keep the nurse, and to draw her milk by artificial means. This very probably need not be done for more than a fortnight, for by that time the labial chancre is likely to appear on the child. If the nurse has already contaminated the child before any discovery is made, then it is best to let her continue suckling, as no further harm can be done, and many complications might arise should the nurse be sent away. The possibility of instituting a system of certificates was then lengthily argued. Should all wet-nurses be called upon to obtain a certificate from the family medical practitioner—stating that they had not nursed a child affected with a contagious disease—before leaving and seeking a new place? Or should the parents, who applied for a wet-nurse, sign an engagement pledging themselves to give the wet-nurse a certificate, when she left, to the effect that the child she had suckled was not affected by hereditary contagious disease? Syphilitic parents, in that case, would not be able to apply for a nurse. A case was related where nine nurses had, in succession, been contaminated by one infant. As the reporter eloquently remarked, it is impossible to decide which is most surprising—the total absence of moral sense on the part of these parents, or the condition of the law which renders it possible for such disastrous and cruel facts to occur. M. Duvernet, who, at the Prefecture of Police, is entrusted with the inspection of wet-nurses, now adjourns for two months the granting of authorisation to wet-nurses to apply for service, when he finds that they have been sent away from a house without any reason being assigned by the family or by the doctor. This proceeding, confessedly most unjust to the nurses, is only done because it is feared that they may have contracted syphilis. The nurse is made to suffer, is deprived of her chances of employment, because the infant she had been nursing may perhaps have inherited syphilis from its parents. Thus is the nurse punished through no fault whatever of her own, and yet M. Duvernet does not dare act otherwise for fear of spreading syphilis in healthy families. Notwithstanding the painful situation here depicted, the Congress could not come to any decision as to a system of certificates. Dr. Brouardel, for instance, related that among his patients he had a client who was the father of five very healthy children, but the sixth and seventh child were both syphilitic. He was a man who thought himself absolutely cured, who could have obtained and have given all the certificates required. The sixth question in the report was thus worded: "A husband formerly had syphilis; a family doctor has followed the case throughout; how many years after he has been cured would it be safe to permit this person to give his child to suckle to a healthy nurse?" It was generally agreed that this question could not be answered; though, as a rule, it was thought that if, after three years' treatment, two years passed without any accident, then there was not much danger. Finally, it was inquired what was the position of a medical man summoned for an accouchement and asked to select a nurse. He knows nothing of the antecedents of the family. He cannot examine them; he can hardly question them on so delicate a question. In such a case it would be more prudent to urge that the family doctor should be consulted, and that the family doctor should decide which wet-nurse, if any, ought to be employed. With regard to the origin of syphilis, whether it began with the nurse or the child, this can generally be established by the date of the appearance of the first symptoms. Dr. Lacassagne suggested that the infant might be dead and buried before the chancre appeared on the breast of the nurse. In that case exhumation, and the examination of the liver and the bones, would probably decide whether the nurse had a right to claim damages. After some more general remarks the discussion closed. Dr. Morel-Lavallée may be congratulated on having fairly puzzled the Congress by his series of questions, which certainly illustrated in a very graphic manner the great difficulties of the subject.

THE BRITISH DENTAL ASSOCIATION.

NOT the least interesting part of the meeting of the British Dental Association last week at Brighton was the demonstration day, and here, as in the papers read, a great deal of attention was devoted to anæsthetics, purely from a dental point of view. Dr. Frederick Hewitt anæsthetised several patients with a mixture of oxygen and nitrous oxide, one part of the former to seven of the latter, the gases being mixed at the time of operation in a gasometer supplied from compressed-gas bottles. The advantages Dr. Hewitt claims for the admixture of oxygen with nitrous oxide are: that it is even a safer anæsthetic than nitrous oxide alone, for the element of danger in the latter—asphyxia—is eliminated; that it gives the operator greater facility, owing to the flaccidity of the muscles and the absence of jactitations and stertor; and also, as a minor but still practical point, that lividity of the features—such an alarming feature to the patient's friends—is entirely absent. In watching the operations, the onlooker, used only to nitrous oxide, might be puzzled to know when anæsthesia was complete, as the stertorous breathing, his chief guide formerly, was not forthcoming. The average relative time of insensibility produced by the two methods—nitrous oxide, and nitrous oxide with 12·75 per cent. oxygen under pressure—has not yet been settled, as only from 200 to 300 cases have been observed; but in the particular cases which we saw, the time under the mixture was as long as, if not longer than, under gas alone. The objection that this method requires a gasometer and the apparatus, and is therefore not easily portable, should be overcome with no great difficulty. Time and an extended number of experiments will show whether this mixture will supersede gas alone, and the best proportions to use, as Dr. Hewitt himself says that some patients do not become insensible under its influence, and he has had then to go on with the nitrous oxide simply.

The production of an analgesic state by "rapid breathing" was also the subject of demonstration at the meeting by Dr. Bonwill of Philadelphia, who has for many years advocated and practised, and was the first we believe to suggest, this method. By getting a patient, he maintains, to breathe atmospheric air at the rate of 100 inspirations per minute, it is possible to render him insensible to pain for any operation not exceeding twenty or thirty seconds. The patient must be warned that he will know all that is going on, but will feel no pain, and must keep up the forced respiration during the whole time of the operation, and "the more energetically he breathes the more perfect the effect." His theory of its action is that there is (1) a diversion of will force; (2) an excess of carbolic acid set free from the tissues, due to the large amount of oxygen passed into the lungs; and (3) cerebral hyperæmia. Physiologically, objections can be made to both of the latter statements, and the effect, when produced, may be furthermore due to exhaustion. Unfortunately, the subjects upon whom Dr. Bonwill experimented would not act up to his instructions, and so no operation was performed, and one can readily understand that, where so much depends upon the voluntary action of the patients, a crowded room, by distracting their attention, may largely increase the difficulty. This shows that there is an insuperable objection to the method, as too much depends upon the patient. Dr. Bonwill was warmly received, and took part in other demonstrations.

THE ROYAL INFIRMARY, HULL.—The financial position of this institution has necessitated an appeal from the Committee for help for present needs and for additional future public support, amounting together to £6000. It appears that the Wilson Wing and the Bailey Out-patients' Departments (the erection of which was defrayed by the inhabitants of Hull and neighbourhood) have been in occupation for two or three years, and entailed an additional expenditure of £1000 per annum, whilst the yearly subscriptions have decreased by about £300 per annum. Moreover, failing the anticipated receipt of adequate funds for endowment, and to cover the increased cost of maintaining the inmates of the new buildings, a debt has accrued to the bankers amounting to £3665, and the Committee ask the public for funds to discharge this claim, and to provide further annual subscriptions to the extent of £2300.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Wolverhampton Urban District.—Dr. Henry Malet gives an interesting and detailed account of the measures taken by his department during 1888 to secure the isolation of cases of scarlatina, from which it would appear that, out of 194 cases heard of, 111 were removed to the borough hospital. But the existing arrangements for the isolation of infectious diseases have been found to be inadequate to the requirements of the borough; indeed it is stated that the authority would be utterly helpless if they were called upon to deal with two diseases simultaneously, besides which the accommodation in the administrative building is altogether inadequate for the staff. It is to be hoped that this matter will without delay be effectually dealt with. Another point of interest discussed in the report is the dangerous practice of trusting to so-called cleansing n the case of wells liable to pollution by soakage of filth. As Dr. Malet points out, the sewage that pollutes a well does not come from the inside but from the outside of the well, and therefore it is useless for an authority or an individual to be content with a process of cleaning out the interior of an excavation into which soakage from without has taken place, and into which the same soakage may again at any moment occur. It is the outside source of the contamination that must be detected, and the possibility of its recurrence should be altogether prevented before any satisfaction can be expressed. This is a point we have often adverted to, and it is one about which there is much ignorance, if we may judge by the action often adopted. The general death-rate for the borough last year was 19·5 per 1000 living.

Wandsworth District.—During 1888 the birth-rate for this district was 29·5, and the death-rate 13·4 per 1000; these statistics not taking account of Battersea, which, since the last annual report was issued, has been separated from Wandsworth. The infant death-rate under one year of age varied from 101 per 1000 registered births in the Streatham to 151 in the Putney sub-district. Measles was very prevalent, and it was also fatal, 53 deaths having taken place; and the medical officers of health jointly point out that, whereas in London during 1888 there were 1209 deaths from scarlatina, no fewer than 2401 deaths took place from measles, and they urge that much less attention than is called for is given to the prevention of this fatal infantile disease. Each of the four medical officers of health appends a separate report on that portion of the district for which he acts.

Bournemouth Urban District.—The general death-rate for Bournemouth during 1888 was 14·0 per 1000 living, and the amount of deaths from any of the infectious fevers was but small. The local infectious hospital is credited with doing much towards the prevention of such diseases, and Mr. Kinsey-Morgan speaks of it as being a model of its sort, as being supplied with a laundry and quarantine cottage, and as being resorted to by high and low, rich and poor. The so-called quarantine cottage seems to be an isolation ward for doubtful cases, such as is now attached to most well-conducted hospitals of this class. The use of salt water for the flushing of sewers, road watering, &c., has been put to the test, and it is stated in every way to answer its purpose. Salt-water baths can also be provided for every house.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5402 births and 3151 deaths were registered during the week ending Aug. 24th. The annual rate of mortality in these towns, which had been 18·8 and 19·2 per 1000 in the preceding two weeks, declined to 17·2 last week. During the first eight weeks of the current quarter the death-rate in these towns averaged 19·6 per 1000, and was 0·6 below the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 11·1 in Brighton, 12·4 in Bradford, 14·3 in Derby, and 14·6 in

Digitized by Google

Huddersfield. The rates in the other towns ranged upwards to 25·5 in Cardiff, 26·5 in Preston, 29·2 in Newcastle-upon-Tyne, and 34·0 in Plymouth. The deaths referred to the principal zymotic diseases in these towns, which had been 785 and 811 in the preceding two weeks, declined again last week to 636; they included 394 from diarrhœa, 60 from whooping-cough, 50 from scarlet fever, 49 from diphtheria, 41 from measles, 41 from "fever" (principally enteric), and 1 from small-pox. These zymotic diseases caused the lowest death-rates in Brighton, Halifax, and Oldham, and the highest in Preston, Sunderland, and Plymouth. The greatest mortality from diarrhœa occurred in Plymouth, Wolverhampton, Newcastle-upon-Tyne, Preston, and Sunderland; from measles in Bradford, Sunderland, Wolverhampton, and Preston; from scarlet fever in Derby and Plymouth; from whooping-cough in Portsmouth, Oldham, Bradford, and Sunderland; and from "fever" in Sunderland and Birkenhead. The deaths from diphtheria included 37 in London, 3 in Plymouth, and 2 in Bolton. Small-pox caused one death in Leeds, but not one in any other of the twenty-eight great towns; and no small-pox patient was under treatment at the end of the week either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and the London Fever Hospitals at the end of the week was 871, against numbers increasing in the preceding eight weeks from 559 to 822; 98 cases were admitted to these hospitals during the week, against 124, 98, and 90 in the previous three weeks. The deaths referred to diseases of the respiratory organs in London, which had been 149 and 162 in the preceding two weeks, declined again to 115 last week, and were 67 below the corrected average. The causes of 57, or 1·8 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Wolverhampton, Bradford, Leeds, Sunderland, and in three other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Sheffield, Huddersfield, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·6 and 17·8 per 1000 in the preceding two weeks, rose again to 18·1 in the week ending August 24th; this rate exceeded by 0·9 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns ranged from 14·0 and 14·6 in Greenock and Edinburgh, to 20·9 and 29·9 in Glasgow and Paisley. The 462 deaths in the eight towns showed an increase of 7 upon the number in the previous week, and included 48 which were referred to diarrhœa, 13 to measles, 11 to whooping-cough, 8 to diphtheria, 7 to "fever," 2 to scarlet fever, and not one to small-pox; in all, 89 deaths resulted from these principal zymotic diseases, against 107 and 87 in the preceding two weeks. These 89 deaths were equal to an annual rate of 3·6 per 1000, which slightly exceeded the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of diarrhœa, which had been 57 and 43 in the preceding two weeks, rose again to 48 last week, of which 24 occurred in Glasgow, 7 in Edinburgh, and 7 in Dundee. The 13 deaths referred to measles exceeded by 3 the number in the previous week, and included 5 in Leith, 3 in Aberdeen, and 3 in Glasgow. The fatal cases of whooping-cough, which had been 24 and 21 in the previous two weeks, further declined to 11 last week, of which 5 occurred in Glasgow and 3 in Edinburgh. Of the 8 deaths from diphtheria 3 were recorded in Glasgow, 3 in Dundee, and 2 in Edinburgh. The 7 fatal cases of "fever" included 2 in Glasgow, 2 in Edinburgh, and 2 in Paisley. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 60 and 57 in the preceding two weeks, further declined last week to 48, and were 27 below the number returned in the corresponding week of last year. The causes of 45, or nearly 10 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·8 and 24·4 per 1000 in the preceding two weeks, rose again to 25·1 in the week ending Aug. 24th. During the first eight weeks of the current quarter the death-rate in the city averaged 22·7 per 1000, the mean rate during the same period being 17·4 in London and 15·9 in Edinburgh. The 170 deaths in Dublin showed an increase of 5 upon the number in the preceding week; they included 20 which were referred to diarrhœa, 4 to "fever," 2 to whooping-cough, 1 to measles, 1 to scarlet fever, and not one either to small-pox or diphtheria. Thus the deaths from these principal zymotic diseases, which had risen from 15 to 34 in the preceding three weeks, were 33 last week; they were equal to an annual rate of 4·9 per 1000, the rate from the same diseases being 2·4 in London and 3·3 in Edinburgh. The deaths referred to diarrhœa, which had risen from 8 to 25 in the previous three weeks, were again 25 last week. The four fatal cases of "fever" showed a slight further increase upon those recorded in the preceding two weeks; while the two deaths from whooping-cough showed a decline of 2 from those in the previous week. The deaths of infants showed a decline from the high number in the preceding week, while those of elderly persons showed a slight increase. Eight inquest cases and 4 deaths from violence were registered; and 50, or nearly one-third, of the deaths occurred in public institutions. The causes of 22, or nearly 13 per cent., of the deaths in the city were not certified.

Correspondence.

"Audi alteram partem."

THE MAYBRICK CASE.

To the Editors of THE LANCET.

SIRS,—Having had some experience of criminal trials, I have had numerous letters and inquiries from professional and other friends asking my opinion on the Maybrick case. I have always answered that I believed Mrs. Maybrick to be guilty; and, having read all the evidence as reported in *The Times*, I should be glad to give a short account of my views in your columns.

It is not disputed that Mr. Maybrick died of gastro-intestinal enteritis, which might have been caused by an irritant poison such as arsenic or by some indigestible article of food. The evidence, however, failed entirely to show that Mr. Maybrick took any sort of food that was likely to make him ill or was subject to any natural causes which might produce enteritis. On the other hand, the evidence proved that arsenic was contained in food and medicine which he did take, and also in food which it was intended he should take but did not take. Now, it was not contended at the trial that anyone but himself or Mrs. Maybrick could have been the means of introducing this arsenic into the various articles referred to; and, further, Mrs. Maybrick stated that she, at her husband's request, put a white powder (which was suggested by the defence to be arsenic) into food in which arsenic was found. Now, after this clear evidence that arsenic was present both in his food and medicine, and with evidence that arsenic was found in the body after death, Drs. Tidy and Macnamara come forward and swear that in their opinion Mr. Maybrick did not die of arsenic. They do not know what caused the gastro-intestinal enteritis, but they do know it was not arsenic, because the whole series of symptoms of arsenic poisoning were not present, and the quantity found in the body after death was less than usual. They entirely ignored the fact that in the great majority of cases of arsenic poisoning, where the symptoms have been accurately observed and reported, solid arsenious acid has been used. It is well known that arsenic is usually administered feloniously in puddings or cakes or other solid or semi-solid articles of diet; but it would be very difficult for Mrs. Maybrick to give arsenic to her husband in this form, as she could not well mix it with solids, and in liquids it would not dissolve easily, but a solution from fly-papers would solve the difficulty; it could be quickly and easily dropped into the medicine or soup. Again, fly-papers were easy to procure, and five years ago two women used them for poisoning purposes, and *were not found out* till they had murdered four persons. Another circumstance which was not pressed home at the trial was the mystery about the arsenious acid found in Mrs. Maybrick's possession. Where and how did she get it? Surely, if it was got for an innocent purpose to

Digitized by Google

kill cats, she might have said where she got it. She was ready enough to give a long account of the fly-papers.

With regard to the medical evidence, the doctors called for the defence appear to have overlooked the fact that a solution of arsenic administered frequently and in small quantities would not be likely to produce all the well-known sequence of symptoms which have been so often described as diagnostic of arsenic poisoning. Neither diarrhœa nor sickness would be so violent, and the presence of petechial spots in the stomach would depend in great measure on violent vomiting; also, inflammation of the eyelids would not be likely to occur except in a chronic case. Lastly, it is improbable that the internal organs would give on analysis the same quantity of arsenic as when administered in a solid or concentrated form.

Judging from the symptoms and analysis of the organs, I have no doubt that Mr. Maybrick died of arsenic administered in his food and medicine; but it was too ridiculous even for the defence to suggest that he himself added the arsenic; therefore, who could have done so but Mrs. Maybrick? She had the motive, she had the arsenic, and she was seen to tamper with the food in which arsenic was found.

I disagree entirely with the evidence given by Drs. Tidy and Macnamara, and how two gentlemen of such eminence as medical jurists could form an opinion that a man dying of gastro-intestinal enteritis, with symptoms of arsenic poisoning (with not a scrap of evidence that anything else caused the disease, and with arsenic found in his food and medicine, and in his body after death), did not die of arsenic passes my comprehension.

My conclusion is that the jury showed good common sense in declining to found their verdict on the evidence for the defence. I am, Sirs, yours obediently,

THOS. BOND, F.R.C.S., M.B., B.S. Lond.,
Late Lecturer on Forensic Medicine at Westminster
Aug. 28th, 1889. Hospital Medical School.

TREATMENT OF TUBERCULOUS GLANDS.

To the Editors of THE LANCET.

SIRS,—The leading article in THE LANCET of Aug. 24th on the treatment of tuberculous glands will be read with great interest by all those called upon to treat this important condition. The point that struck me most in the article was the happy absence of all allusion to "linseed poulticing, iodine, and other temporising local treatment." Margate is perhaps the Mecca sought by most pilgrims in search of a cure for tubercular glands, who do not come under the care of the limited number of surgeons who are specially interested in this branch of operative surgery. Patients arrive here from all parts, with their glands in all stages of disease (except the preliminary stages), with the hope that the Margate air will, unaided, dissolve their dead and dying glands and cause them to vanish. As a rule, they have been treated freely with iodine or prolonged poulticing, with the only result that the vitality of the skin has been impaired, while the glands beneath have passed through their stages of necrosis unaffected. Sometimes patients are even warned beforehand not to allow the Margate surgeons to interfere with the knife, our "gland-thirsty" reputation having been spread abroad. I am aware that there are many experienced surgeons who can relate instances in which enlarged glands of a few weeks' standing, or even a few months, have disappeared during the use of the usual local applications (in addition to tonics, change of air, &c.). But, I venture to think most of these cases are cures *post hoc* rather than *propter hoc*. In my own experience, I have never seen a case of enlarged glands of more than five or six months' standing the least bit benefited by local application, although on several occasions I have observed a temporary condition of peri-adenitis subdued by a lead lotion. I am quite sure if those surgeons who are in the habit of dallying with iodine and the old-fashioned unctuous masses of sodden decomposing linseed meal were to see the condition of the glands excised every operation day at the Royal Sea-bathing Infirmary, they would forgive me for throwing stones at the surgical procedure of a past generation, and treat dead glands as they would treat a piece of loose necrosed bone—i.e., with the knife. It is sometimes difficult to decide whether a gland is past recovery or not; in the majority of instances glands do not disappear if they have been persistently enlarged for about six months, though they may be destroyed in a few days or weeks. I might add that the temperature is, in my experience, almost useless as a guide, for in many instances of advanced disintegration it is perfectly normal. With regard to the operation of erasion or gland-scraping, I regret that my experience has not been the same as the writer of the article. For glands thoroughly broken down into an abscess, it is, of course, the best method; and there are cases in which the gland is throughout its extent a cheesy mass; these also admit of satisfactory scraping. But by far the greater majority of cases that come under one's care are those in which glands are enlarged and contain various quantities of cheesy débris. The cheesy part one can scrape away if one happens to hit it off, but the hard hypertrophied part cannot be removed without unjustifiable violence, and it has to be left, with the certainty of its following the fate of the rest of the gland, and eventually it will be discharged through the cicatrix of the original wound, or, more likely still, the wound will never heal up till it has gone. Having found out these facts by experience in my own practice and that of my colleagues, I invariably excise all glands that are enlarged. If by any chance a gland is left, it will surely need a further operation. Sometimes the operations are extensive, but one is less likely to have mischief with a free incision than in poking about deeply in the neck with a small puncture. A few weeks ago I removed over seventy glands from one side of the neck of a boy of twelve, and the wound was practically firmly healed in from eight to ten days; they had existed nearly all his life. It is perhaps a matter of opinion and taste as regards the scar. Personally, I think one long clean scar is better than a number of isolated and perhaps puckered ones. At any rate, it should not in these days be a matter of opinion as to the advisability of removing dead and dying glands with the knife or spoon. It is as idle and unsurgical to hide a permanently diseased gland under a poultice or film of iodine paint, and hope that the ordinary pathological laws may be suspended and that the dead gland may mysteriously vanish, as it is to foolishly tinker with an abscess without opening it, in the feeble hope that it may be one of those rare abscesses that are good-natured enough to cure themselves. Apologising for the length of this letter,

I remain, Sirs, yours truly,

BERTRAM THORNTON, M.R.C.S., L.R.C.P. Lond.,
Surgeon to the Royal Sea-bathing Infirmary,
Aug. 26th, 1889. Margate.

ANÆSTHETICS.

To the Editors of THE LANCET.

SIRS,—Of all the questions which have exercised the medical mind for the last forty years, probably that of anæsthetics has been the most constant, and, one might fairly say, the most vexed. Since Sir George McLeod's address at Glasgow last year the discussion has lulled perceptibly, and what has been written has been too theoretical and inauthoritative, and has borne too much the mark of the pen of the scribe to interest or satisfy practical inquirers. Sir George McLeod, however, spoke from a full and ripe and practical experience of anæsthetics, dating from their earliest introduction into surgical practice, and he spoke, "ὡς ἐξουσιαν ἐχων, καὶ οὐχ ὡς οἱ γραμματεῖς," and gave to the medical world a well-weighed, almost solemn, verdict in favour of chloroform. Perhaps there are a few, but there cannot be many, who can speak as he did from a practical experience of over forty years; but there must be many who, like myself, can speak from an experience of a daily administration of anæsthetics for five-and-twenty years or more. I think the time has come when we should no longer keep silence, for our experience has a peculiar value, inasmuch as it was, *quâ* chloroform, very extensive and well-founded, before nitrous oxide had left the side of the dentist's chair or had ever been exhibited in the operating theatre; before Sir Spencer Wells advocated bichloride of methylene as the very best of anæsthetics; and long before ether had struggled into use and fashion. By us, I can truly say, each new anæsthetic as it was brought out was eagerly and carefully weighed in the balance, our standard always being, of course, "chloroform *properly* administered." Nitrous oxide is still of great use to us; methylene is, I believe, but rarely employed. Clover soon taught us that ether was not the unmanageable and disagreeable agent that we at first took it to be. He

Digitized by Google

removed for us some of its then-to-fore insuperable disadvantages, and now, of course, all good and competent anæsthetists recognise its use and value. We cannot admit, however, that it is either so safe, so convenient, so universally applicable or so agreeable, even when most skilfully administered, as its almost perfect sister, chloroform; and, I believe, we agree almost to a man entirely with Sir George McLeod. We have to thank Mr. Teale for reverting to the subject in his address in the Surgical Section at Leeds last week, and for giving us the result of his experience, though it took the form of a sort of counterblast in favour of ether.

The experiences of these two authorities are as widely different, as are their conclusions. Let me recall what Sir George McLeod said at Glasgow last year. He said, that "*for speed and energy, for ease of application and agreeableness, for rapid recovery with little subsequent trouble, and for safety when properly administered, chloroform is unrivalled.*" Mr. Teale this year, *ex eddem cathedrâ*, lays down that *ether, if properly administered,* can be given, *tute, cito, et jucunde;* but, quotes Mr. Teale, "non cuivis homini contingit adire Corinthum," and this he translates, for the benefit of his hearers, "*it is not every one who knows, and there are some who are incapable of learning, how to administer ether, even with a Clover's inhaler.*" Let me ask, if this quotation is so applicable to etherists, surely is it not much more applicable to chloroformists? And, in argument, ought it not to be applied, in justice, equally to both? Many times since ether became in vogue have I witnessed its administration at the hands of old and young. With few exceptions, and as a rule, the exhibition has been painful in the extreme, and to those who know how ether should be administered, and who know also the virtues of chloroform, it is not too much to say barbarous and reprehensible. *Tutus* it certainly is *not.* And I believe the patients when they tell me, as they almost daily do, that the process is very far indeed from *jucundus.* Nearly every day patients declare to me their aversion to ether and their preference for chloroform. In my own practice I very frequently come across those who cannot take ether, however carefully and skilfully administered. Perhaps I see more than my share of these, for it is well known that I never yet have refused chloroform to anyone. As to the *cito,* the "saving of time," I say, without fear of contradiction, that time is a factor which a competent anæsthetist never dares to take into consideration.

Mr. Teale speaks of the "comfort and convenience" it has been to him while operating since he allowed his assistants to give ether to his patients instead of chloroform. My only answer to this is that an operating surgeon has omitted part of his duty if he has failed to secure the services of a competent anæsthetist for an operation; and if he has done his duty to himself and patient in this respect, I fail to see where the question of "comfort and convenience" to him comes in. Dr. Joy Jeffreys in 1872, we are reminded by Mr. Teale, urged the "fearfully increasing fatality of chloroform." This, at the time, as reference to the medical journals of the date will show, was, to say the least, a great exaggeration, and each year's experience since has given it an ever-increasing refutation. The alarmists, who do such incalculable harm by their cry that "ether is safe, chloroform is dangerous," utterly ignore the fact that in this island alone chloroform is given every day to at least from 1500 to 2000 individuals, or, say, to about 600,000 per annum. And how rarely do we hear of a death *under* it; *from* it almost never. For five-and-twenty years I have never, on any one single occasion, refused chloroform to anyone, and I have given it to those suffering from all forms and conditions of bodily disease—of head, heart, lungs, kidneys, and all other viscera. With my own hands I have given it to not less than 5000 of my fellow-creatures, and have witnessed its administration by others hundreds of times. I give chloroform, or ether preceded by chloroform, as part of my everyday routine, where pain may be thereby remitted, on every possible occasion. It has not yet been my misfortune to witness a fatality under any anæsthetic, but I deem it right to be ever expectant that the dread disaster may one day befal me. Yet I venture in all humility to hope that, should it ever happen, neither I nor the drugs may be justly held blamable, and that my confidence in the use of my trusted agents for the relief of pain may be by such an accident in no degree impaired. Of the many advantages of chloroform, there is one, and not the least, which has received too little attention—namely, that with it we are enabled to rob ether of its terrors, terrors most real indeed to those (and they are not a few) whose nature revolts against its nauseous flavour, and to whom the sense of suffocation so frequently attendant on its inhalation, no matter how carefully or how skilfully administered, is absolutely unbearable.

I entirely agree with Sir George McLeod's verdict in favour of chloroform, yet on many main points I have little doubt that Mr. Teale and I would be found in perfect accord. My general view is, that the πραξις of all anæsthetic-giving is simple enough, and easily acquired. Not so the ἐπιστήμη and the τέχνη. As in all higher crafts, the first is easily *taught;* the second can be taught in part only; but the third, the τέχνη, cannot be taught, and can only be acquired by long experience and natural aptitude. Very easily, and with fairly diligent observance of detail and practice, the ἐπιστήμη of ether-giving may be attained, and the τέχνη is now acquired by not a few. But to become an artist in the administration of chloroform, more practice, sounder judgment, keener and more rapid power of observation, and more aptitude, are requisite and essential.

I am, Sirs, yours obediently,

Leeds, Aug. 17th, 1889. JOHN HORSFALL.

"FUNCTIONAL ALBUMINURIA."

To the Editors of THE LANCET.

SIRS,—By an apparently clerical, but still not unimportant, error in the report of the discussion on albuminuria at Leeds, you have made me say that "Dr. Gairdner was still unconvinced that we could talk of *functional* albuminuria." What I really said was that *physiological* albuminuria is, in my opinion, both an inaccurate and a misleading expression; but that I did not so much object to the provisional term *functional* albuminuria, subject to the construction of it given in your report. The essence of my remarks was contained in the phrase you have quoted in your leading article—viz., that albumen, meaning thereby serum-albumen cognisable by the heat and nitric acid tests, even when casually occurring in the urine, is to be regarded as a kind of danger-signal; but that the danger may vary indefinitely in different cases, and is to be estimated according to principles very well expounded by Dr. Pavy and other speakers, but implying always, in proposals of life insurance, a postponement at least, to allow of more detailed and, in some cases, frequently repeated observations, in respect of which the proposer's own medical attendant may often be advantageously informed of the facts.

I am, Sirs, yours truly,

Glasgow, Aug. 24th, 1889. W. T. GAIRDNER.

THE USE OF ROBURITE IN MINES.

To the Editors of THE LANCET.

SIRS,—Before Major-General W. H. Wardell had come to the following conclusion—namely, "while expressing my surprise that the writer of your article should have followed the miners' committee in misreading the report of the experts, &c.,"—it would have been well if he himself had not misread the same report, and had also searched for other reports of the poisonous nature of roburite or di-nitro-benzol. I need only here notice that he states it was proved at the inquest on the man who unfortunately met with his death at the Roburite Works at Gathurst "that the poor man died from the effects upon a weak heart, &c." He then goes on to say "that other healthy men had repeatedly done the same without receiving any sensible harm," whereas at the inquest there was no evidence of the deceased having a weak heart previously to the poisoning, and, again, that the other men had sensibly suffered from cleaning this very flue, and every precaution was laid down for them, and the men were paid double for doing this dangerous work, as well as only allowed to remain a short time in the flue, showing that the authorities knew of the danger the men were submitting to.

I would respectfully call the attention of Major-General Wardell to the following articles which have appeared lately in the medical papers:—On Poisoning by Roburite, by J. Ross, M.D., LL.D., F.R.C.P. Lond.; on Acute Poisoning by Nitro-Benzol, by Dr. Reynolds, M.R.C.P. Lond. (*Manchester Medical Chronicle* for May); on the Effects of Nitro-Benzol, by R. Prosser White, M.B. (*Practitioner* for June); Case of Poisoning by New "Sicherheit" Explosive, by William Sykes, M.R.C.S., and F. Gramshaw

Digitized by Google

Twigg (*British Medical Journal*, July 20th, 1889, p. 127); Poisoning by "Sicherheit" Explosive, by H. J. Knight, M.R.C.S. (*Ibid.*, Aug. 3rd, 1889, p. 244)—Mr. Knight mentions that in Dr. Swaine Taylor's work a fatal case is reported; and Poisoning by "Sicherheit" (a new Explosive), by John Stokes, M.B., B.S, M.R.C.S. (THE LANCET, Aug. 24th, 1889). Surely, Sirs, no unprejudiced observer would compare the effects of di-nitro-benzol (or roburite) with the fumes of gun-cotton, nor would they find fault with your article for stating that it is "a very poisonous compound," after considering these papers.

I am, Sirs, your obedient Servant,

August, 1889. THE WRITER OF THE ARTICLE.

TASTE FUNCTION OF THE GLOSSO-PHARYNGEAL NERVE.

To the Editors of THE LANCET.

SIRS,—In your otherwise accurate report of the proceedings of Sections at the Leeds meeting I notice two errors in the paragraph referring to my paper on the above subject. I am reported to have said: "There was some pain and numbness, which might be due to the interference with the blood-supply to the descending tract on that side." This should be: "The partial hemiplegia was to be accounted for by the interference with the blood-supply of the descending tract." Your report also has: "The evidence of pressure on the nerve was the loss of taste on one side of the tongue." As the object of the paper was to show that loss of taste having occurred owing to pressure on the nerve, therefore the glosso-pharyngeal must be considered to be a nerve of taste in opposition to the view held by Dr. Gowers, the concluding paragraph as reported would be a begging of the entire question, and have no bearing on the object of the paper.

As the former of these two errors represents me as having made a mistake impossible even to a beginner in neurology, I trust you will be able to find room for this correction.

I am, Sirs, yours obediently,

Leicester, Aug. 26th, 1889. FRANK M. POPE, M.B., M.R.C.P.

ECTOPIC PREGNANCY.

To the Editors of THE LANCET.

SIRS,—Mr. J. N. Thomas's admirably narrated case is one of the many observations which are being rapidly accumulated to prove that "clear and decided teaching on the theory and practice of extra-uterine pregnancy" has at last been arrived at. There can be no doubt that Mr. Thomas's patient had a tubal pregnancy, and that on April 23rd the tubal expansion ruptured into the cavity of the right broad ligament, forming the extra-peritoneal hæmatocele, which requires no treatment as a rule. In the cataclysm the ovum died, and the whole thing was quietly absorbed, as extra-peritoneal hæmatoceles generally are. The case, in fact, forms a perfect illustration of variety *e* of tubal pregnancy in the scheme given on page 8 of my book on "Ectopic Pregnancy and Pelvic Hæmatocele."

I am, Sirs, yours obediently,

Birmingham, Aug. 22nd, 1889. LAWSON TAIT.

MR. WHEELHOUSE'S ADDRESS.

To the Editors of THE LANCET.

SIRS,—I hope the above address will be brought under the notice of the general public, and that the attention of members of Parliament will be especially called to those portions of it which have reference to pupilage as the best mode of commencing medical studies. The Privy Council is now medical king, and to it and not to the medical corporations must the mass of the profession look for the reform so ably advocated by Mr. Wheelhouse. Hence the necessity of putting the address in lay hands. I would suggest to Mr. Wheelhouse to republish it in pamphlet form and send a copy to each member of the Legislature and to each Privy Councillor. I would observe that in order to make pupilage a reality it should be registered from the commencement of the apprenticeship, otherwise practitioners would be found base enough to sign certificates for apprenticeships never served. There should also be some proof that the practitioner possessed opportunities for teaching, and possibly even the will and capacity to teach. The great English Colleges throw no obstacle now in the way. It is different with their obscure Irish rivals. Intending students and candidates for diplomas would best consult their own interests by turning their faces Londonwards, as three-fourths of them ultimately will find employment outside Ireland. Let me, in conclusion, call the attention of medical members of Parliament and of the whole profession to the new Dublin Hospitals Bill, and to ask them to insist that no hospital shall under that Bill be allowed to dip its hands into the pockets of the taxpayers which does not consent to throw open its medical appointments to public competition. Is it to be tolerated that our taxes are to maintain institutions which select their staffs by the system which prevails at present in Dublin? I am, Sirs, yours truly,

Cashel, Aug. 22nd, 1889. T. LAFFAN.

THE PREVENTION OF INFECTIOUS DISEASE.

To the Editors of THE LANCET.

SIRS,—Allow me to suggest to Mr. Ritchie through the medium of your columns that he should bring in a Bill to compel every landlord, on letting his house, to produce, under a heavy penalty in default, a certificate of recent date, from one holding a recognised public health diploma, stating that the sanitary condition of the house about to be let is in every way perfect. In those cases where the rent is below a certain figure the certificate might be granted by the qualified district inspector for a certain minimum amount. The necessity for some such law may be shown by the following case. I was a short time ago called to see a gentleman suffering from diphtheria, and, after going over the possible causes of the attack, asked him as regards the sanitary condition of his London office. This, he assured me, was all right, as he had had the place inspected by a builder a short time ago. However, I was not satisfied, and requested him to have a properly qualified man to look into the matter thoroughly. To this he consented, and the result was that the house was shown to be in a wretchedly unhealthy state, and the sewer gas to be constantly pouring into the room in which he sat. Now, I ask, what good dual notification would have brought about here? The *origin* of the disease would never have been traced out by it, and several cases might have arisen in other districts by means of the persons who occupied the other equally unhealthy chambers. If Mr. Ritchie will bring in a Bill of the character suggested, he will receive the thanks of all true sanitary reformers, and I do not hesitate to assert that more good will result to the public health in consequence than will ever be brought about by the system which is being so persistently urged upon him by certain members—viz., dual notification.

I am, Sirs, your obedient servant,

Surbiton, Aug. 24th, 1889. F. P. ATKINSON, M.D.

ANTIPYRIN IN CANCER OF THE CERVIX UTERI.

To the Editors of THE LANCET.

SIRS,—I find it highly advisable, for the benefit of patients and for further experiments, to communicate to the profession the favourable result I have obtained by the use of antipyrin in a case of cancer of the cervix uteri, the pain being immediately subdued after its administration. Though this beneficial effect was of short duration, still it was of great importance and satisfaction to the patient. Being summoned to see a European lady, from Port Natal, apparently under forty years of age, I found her suffering from cancer of the cervix uteri in an advanced stage. She complained of severe lancinating pain, worse at nights, disturbing sleep, and of intense fetor of the discharge, and of many other discomforts. She also stated that, having consulted several physicians, she had obtained no relief. The characteristic severity of the pain and fetor of the discharge had reduced the patient to a pitiful condition. It occurred to me that antipyrin perhaps would do her some good, so I prescribed ten grains of it to be given at once in my presence, and great was my surprise, and still greater the satisfaction of the patient, to find the pain, which was so severe before, immediately subdued. Now I repeat the same when the pain comes on, and have observed no unpleasant symptoms arising attributable to antipyrin. I shall communicate any further results.—I am, Sirs, yours faithfully,

M. V. C. MARQUIS, F.S.Sc. Lond., L.R.C.P., &c.

Bombay, July 30th, 1889.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Medals to Nurses.

AN interesting ceremony was enacted at the General Hospital on the 23rd inst. The chairman presented on behalf of the committee a medal to each nurse who had been three years in training, and whose character and competence justified it. There were about twenty recipients. The medals are of silver in the shape of a Maltese cross; in the centre is a monogram "G. H. B.," surrounded by a wreath of oak and laurel leaves. On the back of each is the name of the nurse, with the dates on which she commenced and completed her training. The way in which the work and worth of the recipients are thus recognised will be a valuable incentive to others to do likewise.

The Eight Hours Movement.

A memorial from the gas workers employed by the Corporation has been drawn up, petitioning for the reduction of the hours of labour from twelve to eight per day. They set forth the arduous and unhealthy nature of their occupation, and the fact that in London, Liverpool, and some other places the request has been conceded. If this demand is granted it will make about £17,000 difference in the wages, a heavy item on the working expenses of the undertaking. The movement is not confined to this class of workmen, the tendency being general in favour of the eight hours system for the British workman.

Anti-vaccinationists.

A distraint upon the goods of some ill-advised people for non-payment of fines imposed for the neglect of vaccination has given the opportunity for a meeting to be held in order to protest against the law. As usual, there were fierce denunciations of the existing order. The audience was small, but this was atoned for by those who conducted the meeting. Even an adjourned meeting was insufficient to excite much enthusiasm, and, beyond the usual declamations, the proceedings may be regarded as having been very tame.

Birmingham, Aug. 28th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The late Railway Disaster at Ryhope.

IT now appears tolerably certain that at least fifty persons have been more or less injured by the accident to the Liverpool, Leeds, and Newcastle express train at Ryhope, near Sunderland, on the 19th. The more serious cases have been taken to the Sunderland Infirmary, where they are under treatment, and, I understand, doing well. Dr. Murphy, who was attending the Leeds meeting, was just too late for the unfortunate train, but, following by Durham, he was in time to attend to his cases in the Sunderland Infirmary which were brought in after the accident. We are beginning to hear of some of the remote effects of the accident. For instance, an elderly gentleman, retired from business, but residing at Ryhope, was amongst the first of a large number of people who rushed from the village to render whatever aid might be required by the unfortunate passengers. An additional source of excitement which seemed to add to the other was the fact that it came to his knowledge that one of his grandchildren was in the ill-fated train, and had narrowly escaped a violent death. On his return home he did not seem well, but was able to go about until an hour or so of his death, which took place two days after the accident, to the great surprise of his friends. Lieutenant-Colonel Hutchinson, as an inspector from the Board of Trade, has arrived at Ryhope, and is holding a private inquiry into the cause of the accident. The public will have to await the report of the Board upon the matter before they learn to what the court of inquiry ascribes the accident.

Death of Mr. C. Tennant, M.R.C.S.

The inhabitants of a wide district between Durham and Sunderland were grieved to hear of the death of Mr. Chas. Tennant, surgeon, of Newbottle House, on last Saturday. Mr. Tennant, who studied at Edinburgh, was an M.R.C.S. Eng., and had practised in the villages of the north-east of Durham for thirty years. He was a kind friend to the poor and courteous to all. In his earlier career he had acted as ship's surgeon in whaling expeditions off the coast of North America, and his narration of his experience there and amongst the frozen regions of the Esquimaux was a pleasure his friends were ever eager to enjoy. The writer of this notice has heard him, also, leave these ice fields, in conversation, and pass on to the pleasant hunting fields of Leicestershire; and here he was always at home, and in his day has often "ridden to hounds." "I was my brother's rough rider," he would assert, with pardonable pride, "when he owned six hunters." Mr. Tennant was a native of that far-famed hunting county, and his love of sport was in-bred. Mr. Tennant was also a remarkably fine shot, and regularly went every season to his shooting preserves in the north. He was a man of fine features and presence, standing over 6 ft. 3 in. in height, and proportionately built; and although he was about seventy years of age he looked much younger, and apparently likely to live many years when the writer of this saw him a few months ago. But since then his district has been ravaged by enteric fever, and "the old doctor," as he was affectionately called by the people, was severely worked day and night, the incessant toil making heavy inroads on his strength. He leaves two sons and one daughter. Mr. Tennant was always ready to take an active part in any movement likely to benefit the people of his district.

Death of Mr. J. Jobson, F.R.C.S.

Mr. John Jobson, F.R.C.S. (Bishop Auckland) died at his residence on Saturday last. Although he had reached the age of eighty, and his health was failing lately, his death was somewhat unexpected. Mr. Jobson was a nephew of the late Dr. Frost of Newcastle, with whom he served a portion of his apprenticeship, also with Dr. Leighton, a well-known practitioner at that time in Newcastle, where I believe he had Dr. Embleton as a fellow pupil. Mr. Jobson distinguished himself in the cholera epidemic in Newcastle and Gateshead in 1831, and shortly afterwards removed to Bishop Auckland, where he was some time a partner with Dr. Canney, senior. Mr. Jobson was for a long time the foremost surgeon in the district, being a good operator and all-round practitioner. He took an active interest in the Volunteer movement from its commencement, and rose to the rank of colonel. He was also a J.P. for the county, and one of the presiding magistrates on the Auckland bench for over twenty years. His funeral, which took place on Monday last, was attended by a large number of the local gentry and tradespeople as well as medical practitioners.

Newcastle-on-Tyne, Aug. 28th.

DUBLIN.

(FROM OUR OWN CORRESPONDENT.)

The Dublin Hospitals Board Bill.

IT is satisfactory to learn that this Bill has been discharged, and therefore it will be unnecessary to give a *résumé* of its provisions; but a few observations on an unsatisfactory measure bearing on the objections which must strike the most casual observer may not be out of place. One very important objection to the Bill was the proposal that every hospital participating in any grant should contain not less than 80 beds, and after five years not less than 100 beds, in daily occupation throughout not less than nine months of the year, in respect of which a grant was made. This condition, however, did not apply to the two lying-in hospitals. Now, if we examine the last return of the hospitals which at present participate in the Government grant, we find that the average daily number of beds occupied in those institutions was as follows:—Steevens', 78; Meath, 84; Cork-street Fever Hospital, 43; St. Mark's Ophthalmic Hospital, 42; and the Hospital for Incurables, 167. It follows that the last-named institution and the Meath could only participate in a grant under the proposed Bill. Besides this, each institution obtaining a grant must have not less than fifty paying students on its books during the year, and as the majority of the Dublin hospitals are comparatively small institutions this proviso would disqualify, with few exceptions, every hospital in the city.

Digitized by Google

Further, the Adelaide Hospital, one of the largest and best-managed institutions in Dublin, in consequence of an adverse clause in the Act, would not get a farthing; while, on the other hand, the Mater Misericordiæ Hospital, which does not at present participate in the Government grant), and which, I believe, is well endowed, would, under the Bill, take the lion's share of the suggested grant of £11,500. My last objection is that by the Bill it is proposed that the compensation (if any) to be given to those medical gentlemen who may be deprived of their offices by the closure of the institutions with which they are connected should be subtracted from the £11,500, the amount of the grant, instead of being paid by the Treasury out of a separate fund. If the Bill is ever to become law, it must be materially changed, otherwise the opposition against its passing must be fatal.

Royal Hospital for Incurables.

The Victoria Jubilee Wing is now completely finished, and in the four wards there are at present ninety-one patients. These wards are airy and cheerful, and possess every modern improvement which can ameliorate the condition of the inmates.

Royal University of Ireland.

The Marquis of Dufferin, the Chancellor of the University, will preside at the public meeting for the conferring of degrees, to take place on Monday, Oct. 28th.

Dublin, Aug. 27th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The International Congress on Hypnotism.

Of the many Congresses recently held in Paris, that on "Hypnotism, Experimental and Therapeutic," if not altogether the most interesting, was, at any rate, the most novel, for it was the first International Congress ever held on this subject, and, in fact, one of the rare attempts made by competent men assembled together to rescue it from the hands of charlatans, quacks, and conjurors. Speaking generally of the medical profession, and especially of the English section of it, the tendency hitherto has been to look askance on the whole surroundings of the alleged phenomena, associated with what is known since recent times under the name of "hypnotism." Nay, more: the inclination to look with dubious misgivings on anyone in the profession who meddled in the matter, or who claimed any therapeutic or other good effect, or even real existence, for the cerebral phenomena in question, has been manifestly the fashion; rather has the whole thing been condemned or passed over as deceptive or hysterical trickery. Enthusiasts have from time to time arisen in its defence, who, in claiming everything for it, have, like most enthusiasts, ridden their hobby to death, but who have, doubtless, in a large measure owing to this exaggerated faith, hitherto only succeeded in burning their fingers. Warned by such examples and the general suspicion pervading the whole hypnotic atmosphere, ordinary individual inquirers have, with comparatively rare exceptions, until now, rather suppressed the natural curiosity within them to probe the matter to the bottom, or have done so, as it were, by stealth; and hence, whatever there is, good or bad, false or true, in these mental phases has been entirely abandoned to mountebanks and showmen. This certainly seems, after all, a puerile attitude to adopt in reference to the question. It would appear better, instead of looking upon it as a double-edged tool and relegating it to the realms of doubt and suspicion, or putting it out of sight in the shade of some abstrusely written psychological and rarely read volume, to bring it manfully into the light of ordinary medical instruction and discussion, so that general experience and inquiry might elucidate it, and by so doing finally condemn or establish it in its claim to a respectable existence or its right to be admitted amongst our therapeutic methods. Now the Congress just held marks the first serious effort to bring together the scientific men of different nations for the express purpose of arriving at an international understanding on the subject. It held its sittings in the Trousseau lecture theatre of the Hôtel Dieu, which was tastefully decorated with the flags of the several European and American nations, but which proved much too small to contain the number of members and visitors. Over a hundred medical men, French and foreign, responded to the summons of the organising committee. Amongst the foreign were MM. Dekhterew of St. Petersburg, Delbœuf of Liège, Forel of Zurich, Ladame of Geneva, Masonin of Louvain, and Semal of Mons. M. Dumontpallier, the President, at the opening sitting, traced rapidly the history of scientific hypnotism, the progress of which was in a large measure due to the researches of the school of the Salpêtrière and of that of Nancy, but the popular knowledge of which in the profession dated back to very recent days only. The study of scientific hypnotism, said the speaker, began in 1876 only, when a commission was nominated by the Biological Society to report on the experiments in metallo-therapie of Burq. The recognition of certain effects produced by metals led the commission to the study of hypnotism, which produced analogous phenomena. M. Dumontpallier, at the Hôpital la Pitié, and M. Charcot, at the Salpêtrière, carried on this inquiry. Then the Nancy school, directed by Liébeault, Bernheim, and Liégeois, worked out one branch or factor in hypnotism—viz., suggestion,—which it made peculiarly its own. Indeed, M. Bernheim endeavours to show that under suggestion may be included nearly all the hypnotic phenomena. It is undoubtedly a powerful element, but many other procedures and physical agents may be used to bring about the hypnotic state independently of suggestion. Thanks to the works, then, of Ladame, Grasset, Voisin, Yung, Delbœuf, Forel, Mesnet, and Azam, hypnotism now finds its place in the academies, and no longer meets with opposition from scientific minds. It was still, however, necessary, in order to place this progress on a solid basis, that all experiments should be conducted with scientific reserve and closely criticised, and to consider nothing as a demonstrated fact unless it were confirmed by all or the majority of inquirers. Such in *résumé* was the opening address of the President. The first question which was put before the meeting for consideration was, "The prohibition of all public performances in hypnotism and the necessity of putting hypnotism under legal control." M. Ladame of Geneva strongly insisted on the necessity of interdicting all public displays of hypnotism. The discussion at the Academy of Brussels in 1888 sufficiently revealed the dangers to be apprehended from such displays. He himself had seen at Neuchâtel a veritable post-hypnotic epidemic. MM. Bourdon and Dekhterew supported M. Ladame, and added that the last Russian Psychological Congress had voted prohibition. Finally the proposition was put to the vote and carried, and to it was added the following resolution, which was also carried—viz., "That it is desirable that the study of hypnotism and its therapeutical applications be introduced into the curriculum of medical education." MM. van Renterghem and van Eeden of Amsterdam, next communicated the results obtained in the treatment of 414 cases made up of organic diseases of the nervous system, neurotic, mental, and neuralgic cases, &c. The method adopted was the Nancy one by suggestion. In 71 cases there was no result, in 92 slight amelioration, in 98 marked amelioration, and in 104 cases cure; 57 cases were not worked out. After this the Congress proceeded to the discussion of the second question—viz.: "What is the relative value of the different methods of bringing about the hypnotic state and of augmenting suggestion from a therapeutic standpoint"? M. Bernheim, in discussing these points, said that to define hypnotism as induced sleep was not sufficient, for all hypnotised subjects do not sleep. Some have profound sleep, with amnesia on waking; others also sleep deeply, but recollect their hypnotic period; a third category fall into a light sleep only; and, finally, there are others who do not sleep, or believe they do not. The degree of suggestibility varies with each one of these groups, and is very high in the first; the second are also subject to fairly complete suggestion, but in the remaining groups it is incomplete. For example, one can obtain suggestion of movements and sensation, but not hallucinations. A subject may, however, pass from one to another of these categories. The hypnotic condition, then, is not mere sleep, but a peculiar psychical state, the sleep indicating a profound condition of suggestibility only. The first method employed to bring about hypnotism is that known as Braid's, which consists of fixation by means of some brilliant object. This is the method employed, more or less modified, by the Salpêtrière school to bring about that which is called "le grand hypnotisme" and its three stages. The second method is that which is known as the "verbal suggestion" of

Digitized by Google

Faria. Besides these, there are various other methods, all of which may be successful provided the subject is forewarned. All these methods sum themselves up under suggestion. The fatigue caused by the fixation of vision and the divers passes only acts by "suggesting" the idea of sleep. The so-called hypnotic zones do not exist providing suggestion is avoided. Since all resolved itself into suggestion, "verbal suggestion" was, in the speaker's opinion, the best method. Here he described in detail the methods and practice of verbal suggestion which are to be found in his book on hypnotism. The greatest difficulties experienced by a novice in operating came from "contre suggestions," which resulted from his own hesitations, none of which escaped the observation of the subject, but with practice one can in hospital service hypnotise nine out of ten patients. In order to awaken them, affirmation sufficed, provided it be done without hesitation. M. Bernheim went on to say that suggestion is possible even in a state of wakefulness in certain subjects, in whom every idea is immediately transformed into an act as if the cerebral initiative had not time to intervene. What he called suggestive psycho-therapeutics had for its object the cure of the patient by causing his brain, whether hypnotised or not, to be possessed of the persuasion of cure or the cessation of his symptoms. Suggestion, he declared, had always been exercised, although unconsciously, by physicians. The prescription of inert substances under scientific names was nothing less, and he would add his firm belief that the different methods of hydro-therapeutics, electro-therapeutics, and even the much-discussed suspension in tabes, acted in a like manner. Let us admit, then, concluded the orator, the importance of the *rôle* which the mind has in morbid phenomena, and allow that, as we had psychology, so we had also psycho-therapeutics.

The Levick Institution of English Nurses in Paris.

This is an institution, recently established to supply a want in this cosmopolitan city, which needs only to be known to be appreciated. Our medical *confrères* in the United Kingdom will be glad to know that when their patients come abroad they can, if needed, be provided with an English nurse who has received a thorough training in the hospitals of her own country. It will also be equally welcome to our *confrères* practising on the Continent, who, having received their medical education in British schools, carry with them into practice their British methods and traditions, which there is no gainsaying vary in those many little details which serve to differentiate continental from British medicine, and the sum of which details goes to make up the feeling of comfort, and therefore the greater prospect of recovery, which the English invalid abroad, accustomed to his national habits both in sickness and health, experiences when treated by a British graduate and tended by a British nurse. The institution is situated at 34, rue de Prony, close to the Parc Monceau. Competent nurses can be sent on the shortest notice to any part of the Continent, on receipt of letter or telegram. The registered telegraphic address is "Nurses, Paris."

Paris, Aug. 27th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Next Congress of German Naturalists.

THE next Congress of the German Naturalists is to be held in Heidelberg, and to last from Sept. 18th to the 23rd. Simultaneously with the Congress there will be an exhibition of scientific apparatus, instruments, and preparations in the Gymnastic Hall of the town. Meyer of Göttingen will lecture on the Chemical Problems of the Day; Volgar of Frankfort on the Life and Works of the Naturalist, Dr. K. Schimper; Hertz of Bonn on the Relations between Light and Electricity; Puschmann of Vienna on the importance of History to Medicine and the Natural Sciences; and Brieger of Berlin on Bacteria and Disease Poisons. A banquet, a ball, a *fête* in the old palace, and excursions in the lovely environs will relieve the graver labours of the Congress, and the palace will be illuminated on the last evening.

Prussian Statistics for 1887.

In 1887 there died in Prussia 358,028 males and 328,142 females, and 24,579 males and 19,327 females were stillborn. The death-rate was 23·9 per 1000—25·4 of males, and 22·5 of females. Since 1875 the death-rate had never been so low; 260·7 boys and 218·4 girls per 1000 died in their first year, 66·5 boys and 63·7 girls in their second. For the higher ages the death-rate was as follows:—

Years.	Males.	Females.	
From 3 to 5	20·2	19·9	per 1000
,, 5 to 10	8·1	8·4	,,
,, 10 to 15	3·6	4·1	,,
,, 15 to 20	4·7	4·3	,,
,, 20 to 25	6·6	5·5	,,
,, 25 to 30	7·3	7·3	,,
,, 30 to 40	10·6	9·4	,,
,, 40 to 50	16·1	11·3	,,
,, 50 to 60	26·3	19·0	,,
,, 60 to 70	50·6	43·4	,,
,, 70 to 80	107·4	101·0	,,
Above 80	228·2	217·8	,,

The following were the ratios of deaths per 10,000 from the various undermentioned causes:—Small-pox 0·05, scarlet fever 2·90, measles and rubeola 4, diphtheria and croup 17·64, whooping-cough 5·07, typhus 2·64, petechial fever 0·03, dysentery 0·35, rheumatic fever 0·59, tuberculosis 29·33, cancer 3·83, apoplexy 10·8, pneumonia and pleurisy 14·81, heart diseases 2·71, brain diseases 5·36, diseases of the kidneys 1·99, child-bed 2·09, consequence of accidents 3·96, murder and manslaughter 0·13, and suicide 1·77. In 1883, 6171 persons committed suicide in Prussia; in 1884, 5900; in 1885, 6028; in 1886, 6212; and in 1887, 5893. Of the suicides of 1887, 4703 were males and 1195 females. In 1559 cases the cause assigned was insanity, in 646 grief, in 606 vice, in 592 life-weariness, in 519 physical disease, in 455 shame and remorse, in 193 passions, in 181 vexation, anger, and quarrelling, and in 32 sorrow for bereavement. It is noteworthy that insanity was the cause, or is alleged to have been the cause, in 41·1 per cent. of the women and only in 22·7 of the men—a fact which may be partly explained by the circumstance that insanity is often alleged as the cause of suicide by relatives &c. to veil the real motives. It is also remarkable that grief, which is generally supposed to depress women more than men, is a much more frequent cause of suicide in men than in women. This cause is assigned in the cases of 11·6 per cent. of the men and only of 8·5 of the women. Under the heading of "passions," on the other hand, of which probably love is the chief, the women greatly preponderate, their percentage being 6·5 and that of the men only 2·5.

The Triumph of Medical Science in the Prussian Army.

In a speech at the celebration of the anniversary of the founding of colleges for the training of physicians and surgeons for the Prussian army, Surg.-General Dr. von Coler stated that the number of cases of illness in the Prussian army had sunk 46 per cent., the death-rate 54 per cent., the number of typhus cases from 10·9 to 4·4 per cent., and the loss to the army by typhus from 2·1 to 0·32 per cent., between 1868 and 1887. The reduction of the death-rate means a gain to the State of 1564 soldiers a year.

Cholera in Mesopotamia.

The *Allgemeine Zeitung* of Munich hears the following from Constantinople: "Cholera broke out in Mesopotamia on July 27th, in the same mysterious manner as in Egypt in 1883. That it came from Bombay, *vid* Bassora, is certain; how, has not yet been determined—perhaps, as in Egypt, in the persons of Arab stokers, who serve on board the English steamers of the Bassora-Bombay line, and go home on their arrival at Bassora. It appeared first at Sehatra, a place of 3000 inhabitants, two and a half days' journey from Bassora, on the canal Schate el Hay, which unites the Tigris with the Euphrates; 308 persons died between July 27th and Aug. 6th. On Aug. 1st it broke out at Nassrié, a place of 8000 inhabitants, south of Sehatra, and near the junction of the Schate el Hay with the Euphrates: 293 persons died there between Aug. 1st and 9th, of whom eighty-five died on the 8th alone. This town has a swampy flat, and consists of mere reed huts. Its main industries are rice-growing and, in a less degree, cattle-breeding. The epidemic broke out in Bassora on Aug. 6th, and its first victim was an Arab girl, who had arrived from Filie in Persia ten days before. The number of deaths on the 9th inst. was fifteen. The reports of the medical officer, Gazala, leave no room for doubt as to the diagnosis."

Dr. Robert von Helmholtz.

Dr. Robert von Helmholtz, a son of the famous scientist, died here two or three weeks ago, aged only twenty-eight.

Digitized by Google

Though the time allotted him was so short, and his life much marred by delicate health, he has left behind him a series of scientific writings not unworthy of the great name he bore. They are almost all of a strictly scientific character, and treat of vapours and mists, the relations between the freezing-point and steam tension, and experiments with a steam jet. They are of practical value in meteorology. Only one of Robert von Helmholtz's writings penetrated to non-scientific circles. It was published in the *Deutsche Rundschau*, and contains the author's boyish reminiscences of the famous physicist, Gustav Robert Kirchhoff, when the latter and Hermann Helmholtz, then Professor of Physiology at Heidelberg, lived and worked in the same house in the beautiful town on the Neckar. Young Helmholtz's chief teachers were his own father and Robert Bunsen. It is sad to think that one who had gained so high a place among the younger scientists of the age has not been permitted to fulfil the brilliant promise of his youth, and add new lustre to a distinguished name.

Berlin, Aug. 21st.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Census of Mortality and Vital Statistics.

THE eleventh census of the United States is about to be taken, and the superintendent has issued a circular to the medical profession. As we have no national system of registration of vital statistics, our census affords the only opportunity of obtaining an approximate estimate of the birth and death rates of much the larger portion of the country, which is entirely unprovided with any satisfactory system of state or municipal registration. To secure the co-operation of medical men, the Census Office has issued a blank physicians' register of deaths to the entire profession, with the request that, commencing on June 1st, they will enter the death of each person coming under their own cognisance, with all the particulars of sickness, &c. When the year has expired, these registers will be returned to the central office for statistical reduction.

New Building for the Academy of Medicine.

The Academy of Medicine is about to erect a new and commodious building in a more central portion of the city. The allotted space measures 75 by 100 feet. The building will be five stories high. The interior arrangement provides a large audience room, a library room with a capacity for 230,000 volumes, section rooms accommodating respectively 160, 225, 275, and 110 persons, rooms for laboratory and microscopic work, and rooms for study, smoking, and conversation. Such a building has long been the great want of the profession in this city. When completed it will unite in one interest all of the now scattered societies.

Execution of Criminals by Electricity.

Although the law requiring the execution of criminals by electricity in this State came into operation on Jan. 1st last, the execution of the first criminal by this means has been stayed by judicial proceedings taken to determine the effectiveness of the method and the constitutionality of the law. A large amount of evidence is now being taken as to the power of electricity, when created by apparatus, to destroy human life. It now appears that the resistance of the human body is liable to be such that the electrical current will not destroy life, but will only temporarily paralyse. Edison, the inventor, takes strong grounds in favour of execution by electricity, and declares that death can be effected with the greatest precision; but many experts in the use of electricity disapprove the method. The final report of the referee will be awaited with interest. Meantime the preparations for the execution are steadily progressing.

Payment for Reports of Births.

There has been much complaint among medical practitioners of the injustice of being compelled to report births and deaths, and pay the postage on their reports, without compensation and under heavy penalties for neglect. This sense of wrong has led many physicians to neglect such reports, and the results of such neglect are seen in vitiated vital statistics. One State, Massachusetts, has applied the proper remedy—viz., the giving of a fee of a quarter of a dollar for every birth reported in proper form. The effect of this liberal law has been to greatly increase the number of cases reported.

Prevention of Quackery in the new States.

The rapid formation of new States, with complete forms of government, now in progress, is a remarkable feature in the civic history of the United States. The only restriction placed upon the organising bodies is that State governments shall be Republican in form. In most of these new States very advanced opinions prevail in regard to State Medicine. Stringent health laws are passed, and growing out of these are laws for the suppression of quackery. In this respect the new States are far in advance of the older ones, which are very slow to take this advanced step. In many of the new States there are no irregular practitioners.

New York, Aug. 8th.

THE SERVICES.

ARMY MEDICAL STAFF.—The undermentioned Surgeons to be Surgeons-Major, ranking as Major (dated Aug. 5th, 1889):—Francis Henry Swinton Murphy, M.D.; William Thomas Johnston, M.D.; Abraham Walker Browne; Robt. Doveton Hodson; Caleb K. Powell, M.D.; Hugh Cunningham Kirkpatrick, M.D.; John Armstrong; Wm. Wallace Kenny, M.B., F.R.C.S. Ireland; Philip Mackay Ellis; Patrick Joseph O'Sullivan, M.D.; and James FitzGerald Brodie, M.D.; Surgeon Phineas Barrett Tuthill, M.D., F.R.C.S. Ireland, to be Surgeon-Major, ranking as Major (dated Aug. 8th, 1889).

MILITIA (Infantry).—9th Battalion, the Rifle Brigade (the Prince Consort's Own): Surgeon-Major R. V. Kelly resigns his commission; also is permitted to retain his rank, and to wear the prescribed uniform on his retirement (dated Aug. 24th, 1889).

ADMIRALTY.—The following appointments have been made:—Surgeon William M. Lory to the *Penelope*, additional, for Ascension Hospital, and Surgeon Percy W. Bassett-Smith to the *Nankin* (both dated Aug. 28th, 1889); Fleet Surgeon George Kell to the *Wildfire*, for charge of medical duties of Sheerness yard, Naval Barracks, and ships of Steam Reserve, and Surgeon Vidal G. Thorpe to the *Belleisle* (both dated Aug. 26th, 1889).

VOLUNTEER CORPS.—*Artillery:* The Tynemouth: Acting Surgeon H. Bramwell, M.D., to be Surgeon (dated Aug. 24th, 1889).—*Engineers* (Fortress and Railway Forces): 1st West Riding of Yorkshire (Sheffield): Acting Surgeon C. H. Willey, M.D., to be Surgeon (dated Aug. 24th, 1889).—*Rifle:* 1st Volunteer Battalion, the Cheshire Regiment: Acting Surgeon A. Craigmile, M.D., to be Surgeon (dated Aug. 24th, 1889).—2nd (Berwickshire) Volunteer Battalion, the King's Own Scottish Borderers: Alfred Dorriforth Vardon, Gent., to be Acting Surgeon (dated Aug. 24th, 1889).—2nd Volunteer Battalion, the East Surrey Regiment: Acting Surgeon W. Gandy to be Surgeon (dated Aug. 24th, 1889). — *Memorandum* (Infantry Volunteer Brigade)—North Midland Brigade: Surgeon and Surgeon-Major W. Milligan, 2nd Volunteer Battalion, the Sherwood Foresters (Derbyshire Regiment) to be Brigade Surgeon, ranking as Lieutenant-Colonel (dated Aug. 24th, 1889).

THE NEW VICTORIA EYE AND EAR HOSPITAL, HEREFORD.—The ceremony of formally opening this institution was performed on the 20th inst. by Lady Bailey, the wife of the member for the city, Sir J. R. Bailey, M.P. The building is erected on the most approved sanitary plans, and contains excellent administrative accommodation, surgery, operating-rooms, &c. There are four wards, one large and one small, for each sex. For the present, the two larger wards will have four beds each and a child's cot or two, and the smaller two beds each. The cost of the hospital has been £2400, and towards the site and building fund £1610 has been subscribed or promised.

AMBULANCE WORK.—On Saturday last, at the People's Palace, Mile-end, Princess Frederica of Hanover distributed the medallions and certificates to the successful students of the St. John Ambulance Association classes in the metropolitan centre, which includes the city and Port of London and the East-end.

Medical News.

ARMY MEDICAL SERVICE.—The following is a list of the successful candidates at the recent competitive examination for commissions in the above Service:—

	Marks.		Marks.
Waller, H. J.	3085	Stone, C. A.	2800
Bewley, A. W.	3080	Way, L.	2730
Mould, W. T.	3030	Moores, S. G.	2640
Hughes, M. L.	2910	Winter, H. E.	2630

NAVAL MEDICAL SERVICE.—The following gentlemen, who competed at the examination recently held at Burlington House for appointment as Surgeon in the Royal Navy, have been successful:—

	Marks.		Marks.
G. Allan, M.B.	3100	N. C. Ridley	2920
W. J. Maillard, M.B.	3065	A. H. L. Cox	2885
P. V. Jackson	3010	E. F. S. McKay	2880
O. M. Jones	2920	A. Maclean, M.B.	2880

INDIAN MEDICAL SERVICE.—The following is a list of the candidates for the above Service who were successful at the competitive examination held at Burlington House on Aug. 12th and following days:—

	Marks.		Marks.
A. L. Duke	3400	C. L. Williams	3190
H. B. Melville	3380	C. H. Bedford	3145
J. C. S. Vaughan	3380	W. C. Vickers	3115
H. F. Cleveland	3260	J. C. White	3105
J. B. Smith	3240	E. L. C. Smith	3060
T. W. Shaw	3205	H. W. Elphick	3050

Fifty-six candidates competed for twelve appointments; fifty-five were reported qualified.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates, having passed the qualifying examination in Medicine, Surgery, and Midwifery, have received certificates entitling them to practise in the same, and were admitted Licentiates of the Society on the 16th inst.:—

Greenwood, Samuel, Queen's College, Birmingham.
Jessop, Arthur Rowland, Guy's Hospital.
Rees, Edward Davies, King's College Hospital.

Passed on the 21st inst.:—

Bate, John, London Hospital.
Blewitt, Patrick Lyons, Dublin.
Buée, Kenneth Frederick Tooke, University College Hospital.
Case, William, King's College Hospital.

Passed on the 22nd inst.:—

Ilott, Arthur Talman, Charing-cross Hospital.
Walton, John Stamford, Newcastle-on-Tyne.

RABIES.—The *London Gazette* of the 23rd inst. publishes the usual returns of the number of cases of contagious or infectious disease under the Contagious Diseases (Animals) Act in Great Britain during the week ending the 17th inst. For the first time since the enforcement of the muzzling order no cases of rabies among dogs are reported.

NEW HOSPITAL AT ALDERSHOT.—On the 26th inst., at Aldershot, Lady Wood, the wife of Sir Evelyn Wood, the lieutenant-general commanding the division, formally opened the new buildings connected with the Female and Children's Hospital, which comprise three wards, named respectively the "Stanhope," the "Connaught," and "Dorothy."

FEVER HOSPITAL, HOMERTON.—On Tuesday night, a fire broke out at the ambulance station of this hospital. The furnace-room on the ground floor of the building caught alight. The flames burnt through the roof, but, after an hour's work by the fire brigade, were subdued. The roof of the laundry became also ignited, and some damage was done to the harness store. The cause of the fire is unknown.

NORTH DEVON INFIRMARY.—Dr. R. Budd presided at the sixty-third annual meeting held at Barnstaple on the 20th inst. A letter was read from Lord Fortescue offering to pay £150 odd, the cost of some sanitary improvements in the establishment, which was accepted. The report showed a falling off in the year's receipts of £184 4*s*. A new system of ventilation and some efficient drainage works had been carried out at an outlay of £426. During the year the Convalescent Home at Morthoe had been built and endowed by Mr. W. F. Rook and his sister and patients from the Infirmary sent there. The medical report stated that 512 in-patients and 2208 out-patients were admitted during the year.

THE ROYAL COLLEGE OF SURGEONS.—The library and museum of the College will be closed during the month of September for the purposes of cleaning.

FEVER AT CAIRO.—Recent advices announce the continuance of admissions of fever cases to the hospital at Cairo. There are said to be now 300 cases under treatment in the institution.

QUARANTINE.—According to the *London Gazette* the British representative at Alexandria has telegraphed as follows:—"Lohaya to Moka, inclusive, released from quarantine." The British representative at Constantinople has telegraphed that fifteen days' quarantine has been imposed at all Turkish ports against all ports in the Persian Gulf.

STRATFORD-ON-AVON HOSPITAL.—At the annual meeting of the governors and friends of this hospital on the 26th inst. a satisfactory statement was made as regards its financial position, an increased income being shown as compared with that of last year. Moreover, a debt of £282 had been paid off. The number of in-patients during the year had been 202, and of out-patients 509.

OPHTHALMIA AT HANWELL SCHOOLS.—At a meeting this week of the Board of Managers of the Central London District (Poor-law) Schools at Hanwell a tender was accepted for the erection of temporary dwellings for the isolation of 400 ophthalmic juvenile patients, at a cost of £19,600. These schools contain upwards of 1100 children from the unions of the City of London and St. Saviour's Surrey, &c., and of this number upwards of 300 children are affected more or less severely with ophthalmia. In addition to these buildings, it has become necessary to engage a special ophthalmic surgeon and a staff of nurses. These steps are the result of strong, urgent, and long-continued representations from the Local Government Board.

PRESENTATIONS.—On Tuesday, the 27th inst., a number of friends waited on Edward Stamer O'Grady, F.R.C.S.I., at his residence, Merrion-square, Dublin, and presented him with an address accompanied by a brougham and silver-mounted harness, and a handsome bracelet for Mrs. O'Grady. The address was read by Mr. Edward Hamilton, surgeon to his Excellency the Lord-Lieutenant. Mr. O'Grady afterwards entertained those present to luncheon.—Mr. T. A. Collinson, M.R.C.S., L.S.A., having decided to leave the Durham County Hospital, the term of his office as house surgeon for the past two years having expired, the nursing staff of the institution, in recognition of their appreciation of the harmony in which they had worked together, have presented him with a writing-table set of brass ornaments.

MEDICAL NOTES IN PARLIAMENT.

Cotton Cloth Factories Bill.

IN the House of Lords on Thursday, the 22nd inst., Viscount Cross in moving the second reading of this Bill, explained that it was a sanitary measure regulating the amount of acids to be used, so as not to oppress the workpeople. The Bill had been carefully considered, and was an excellent sanitary measure. The Bill was then read a second time. It passed through Committee, with some verbal amendments, on Monday, the 26th.

The Royal Assent.

On Monday, the 26th, the Royal Assent was signified by Commission to the following, amongst other Bills:—The Lunacy Acts Amendment Bill, the Prevention of Cruelty to and Protection of Children Bill, and the Local Government (Scotland) Bill

The Cholera Prevention Bill.

The Public Health (Cholera Prevention) Bill (which passed through Committee and was read a third time in the House of Commons on Saturday, the 24th) was read a first time in the Upper House on Monday, the 26th.—In moving the second reading, on the following day (Tuesday, the 27th), Lord Balfour explained that its object was to remove doubts in regard to regulations the Local Government Board were empowered to make under the Public Health Act, which had been in force for sixteen or seventeen years. It was of great importance that those doubts should be removed.—The Bill was read a second time, and subsequently passed through its remaining stages.

Typhoid in the West-end.

In the House of Commons on Thursday, the 22nd inst., Mr. Ritchie, in reply to Mr. Isaacson, stated that he had no authority to give any

Digitized by Google

directions to the sanitary inspectors of St. George's, Hanover-square, who were in no way subject to the jurisdiction of the Local Government Board. He would, however, communicate with the Vestry of the parish with reference to the sanitary inspectors reporting upon the houses which had open cesspools, and advising as to their immediate removal.

Contagious Disease in India.

In answer to Mr. Cavendish-Bentinck, Sir J. Gorst (Under-Secretary for India) stated that the Cantonment Bill contained provisions for enabling the Government of India to deal with all contagious diseases within cantonments, and regulations for that purpose would be made by the Government of India as soon as the Bill became law.

The Royal Commission on the Blind.

In answer to Mr. Woodall, Mr. W. H. Smith stated that the important recommendations contained in the report of the Royal Commission on the Blind, the Deaf, and the Dumb, would be carefully considered during the recess.

Londonderry Prison Doctors.

On Friday, in Committee of Supply, on the vote for the General Prisons Board in Ireland, Mr. Blane said he was an inmate of Londonderry Gaol in 1888. At that time disease was prevalent. No attempt was made at isolation or at tracing the source, and destroying the cause of disease. The doctor, Sir William Miller, and the officials treated all complaints with indifference and contempt. The money voted for the medical officers of Londonderry Prison was, in the speaker's opinion, entirely thrown away. Mr. Conybeare had fallen a victim to the indifference of the doctors about separating prisoners who were suffering from disease. Prisoners were not put into hospital until they were in a dying state and past cure. The Chief Secretary had stated that the sick-rate of the prison was less than that of the town, but that was accounted for by the fact that sick prisoners were not in hospital. He had himself witnessed cases in Londonderry prisoners where warders had assaulted prisoners in order to provoke resistance, when the prisoners were summoned and sentenced to a further term of imprisonment. The Government could and ought to remedy these things.—Mr. Balfour, in reply, stated that he was accustomed and he was indifferent to attacks made upon himself by honourable members opposite; but when it came to the character of an official like the present medical officer of the Londonderry Gaol the matter became one of great importance. This doctor had been attacked for his want of humanity, especially in the case of M'Gee, who had died of acute tuberculosis. A more outrageous accusation had never been made. Sir William Miller had acted as a most humane and honourable gentleman. The medical arrangements of Londonderry Gaol were in a peculiarly satisfactory condition.—On the following day (Saturday) the subject was resumed, when Sir C. Lewis bore testimony to the high character of Sir W. Miller, the prison doctor, against whom in Derry no one could venture to say one word, such was the high esteem in which he was held by all classes. He challenged any hon. member opposite to say if that was so or not.—Mr. Leamy and Mr. T. Healy continued the attacks upon Sir W. Miller, after which Mr. Balfour again defended that medical officer against the undeserved abuse which had been heaped upon him. The privileges granted by Irish prison doctors to Crimes Act prisoners were enormously in excess of those granted to other prisoners, and the rate of mortality in English prisons was double that in Irish prisons.

The Professors of the Queen's Colleges.

On Saturday, the 24th, Mr. Pinkerton asked the Secretary to the Treasury whether, in view of the serious financial loss inflicted upon certain professors of the Queen's Colleges, by the passing of the Royal University (Ireland) Act, he was prepared to make the same concession to them as was given to medical officers and servants in the Dublin Hospital Board Bill, which he had recently introduced.—Mr. Jackson said he did not recognise any similarity in the circumstances between the two cases referred to.

Infectious Diseases Notification Bill.

The House went into Committee on this Bill. Mr. H. Stewart moved to report progress as many members were absent, and there were no medical men present. The motion was rejected after a discussion by 54 against 18. Clause 1 was agreed to, and a long discussion arose on Clause 2, which Mr. Healy moved to amend by omitting subsection A.—Mr. Ritchie explained that the Bill as it stood proposed to make the Act compulsory in London and optional throughout the country. The amendment would strike out the compulsion with reference to London. He added that the Government proposed to accept the principle of the amendment later on. The amendment was then withdrawn, and the clause agreed to, as were the clauses up to 9 inclusive. On Clause 10 Mr. Ritchie moved to add the words, "The managers shall send weekly to the London County Council such return of the infectious diseases of which they receive certificates in pursuance of this Act as the London County Council from time to time require."—The amendment was agreed to.—On the motion of Mr. Ritchie, the following new clauses were agreed to and added to the Bill:—"A payment made to any medical practitioner in pursuance of this Act shall not disqualify that practitioner for serving as member of the council of any county or borough, or as member of a sanitary authority, or as guardian of a union, or in any municipal or parochial office. Where a medical practitioner attending on a patient is himself the medical officer of health of the district, he shall be entitled to the fee to which he would be entitled if he were not such medical officer." "Where this Act is put in force in any district in which there is a local Act for the like purpose as this Act, the enactments of such local Act, so far as they relate to that purpose, shall cease to be in operation."—Some verbal alterations and modifications were made in the application of the Act to Scotland and Ireland, and the Bill as amended passed through Committee. The Bill as amended was considered and read a third time on Monday, the 26th.—The Bill was taken to the Upper House on Wednesday, the 28th inst., when Lord Balfour, in moving the second reading of this Bill, said that there were now fifty-two urban and rural authorities in whose districts the system proposed under the Bill was already enforced, and no fewer than three and a half millions of people were controlled by those authorities. Therefore the Bill could not be said in any way to introduce a novel principle. A large number of public bodies had petitioned in favour of the provisions of the Bill, and in 1887 a circular was sent to the sanitary authorities and medical officers in all the districts now under the system to which the Bill would give effect. The response to this circular was absolutely unanimous in favour of the Bill. One of the chief advantages of the notification of infectious disease was that it led to a more rapid discovery of the cause. In one town thirty cases of typhoid were notified at the same time, and the cause of the epidemic was at once traced to the milk-supply. The Bill was read a second time, and the Committee stage being dispensed with, the Bill was read a third time and passed.

Health of British Troops in India.

On Monday, the 26th, Mr. E. Stanhope, Secretary of State for War, stated that the ratio of admissions for venereal disease among British troops in India during the first four months of 1888 was 349 per 1000. Sir J. Gorst added that no report was made up with regard to native troops.

Health of Dublin Barracks.

General Fraser asked whether it was true that between the first week of July and the present date the number of cases of enteric fever in the Dublin Barracks had increased 300 per cent. Mr. E. Stanhope, in reply, stated that up to the end of June in the present year the number of cases had fallen far below the number last year, but he regretted to say that there had been a fresh outbreak in July. The works of improvement were being actively carried on, as well as the subsoil drainage which had been recommended. Much had already been done, although, owing to the state of the river, he despaired of eradicating enteric fever altogether at present.

The Fountains in Trafalgar Square.

In reply to Mr. Kimber, Sir H. Maxwell (Lord of the Treasury) denied that the water supplied to the fountains in Trafalgar-square was generally in a foul condition. The water is ordinarily supplied from the artesian well at the back of the National Gallery, and from repeated analyses has been found to be of excellent quality.

Dublin Hospital Board Bill.

On the order to go into Committee on this Bill, Mr. Jackson (Secretary to the Treasury) moved that the order be discharged and the Bill withdrawn, adding the hope that it might be passed next session. The motion was agreed to.

Movable Dwellings Bill.

On Tuesday, the 27th inst., the orders for the consideration, as amended, of this Bill were read and discharged, and the Bill was withdrawn.

METROPOLITAN ASYLUMS BOARD.

Return of Patients remaining in the several Fever Hospitals of the Board at midnight on August 27th, 1889.

Births, Marriages, and Deaths.

BIRTHS.

BAMBER.—On July 29th, at Moultan, Punjab, India, the wife of Surgeon C. J. Bamber, of twins (sons).

CHRISTISON.—On Aug. 20th, at Whyte Knowe, Peebles, the wife of David Christison, M.D., of a son.

COMBE.—On Aug. 23rd, at Holly House, North Walsham, the wife of F. Orloff Combe, M.D., of a daughter.

GIMLETTE.—On Aug. 5th, at Ireland Island, Bermuda, the wife of Staff-Surgeon T. D. Gimlette, R.N., of a son.

JEWSON.—On Aug. 23rd, at Strathleven-road, Acre-lane, Brixton, S.W., the wife of Francis A. B. Jewson, F.I.C., F.C.S., of a son.

LAMB.—On Aug. 20th, at Moira House, Arnold, Notts, the wife of William Lamb, M.D., of a son.

WILKINS.—On Aug. 19th, at 1, Windsor-road, Ealing, W., the wife of H. G. G. Wilkins, L.R.C.P. Lond., M.R.C.S., of a daughter.

MARRIAGES.

BRAIDWOOD—CUNNINGTON.—On Aug. 21st, at St. John's Church, Devizes, P. Murray Braidwood, M.D., F.R.C.S., F.R.M.S., of Shirehampton (late of Birkenhead), to Lydia Mary, eldest daughter of the late Henry Cunnington, of Southgate House, Devizes.

HARRISON—ALLISON.—On Aug. 22nd, at St. Andrew's, Collumpton, Devon, by the Rev. Prebendary J. G. Davis, M.A., Edward Harrison, M.A., M.B. Cantab., F.R.C.S., of Hull, to Mary Jane Allison, widow of the late James Allison, R.N.

LEWIS—WASSELL.—On Aug. 22nd, at Zion Baptist Chapel, Bradford-on-Avon, B. Morgan Lewis, M.R.C.S., L.R.C.P. Lond., son of Benjamin Lewis, Abergavenny, to Marian, daughter of the late Rev. David Wassell, of Bradford-on-Avon and Bath.

MARTIN—HAMOND.—On Aug. 22nd, at the Roman Catholic Church, Spanish-place, Surgeon-Major P. R. Martin, eldest son of the late Richard Martin, Esq., Cro'cloney, Ireland, to Esabella Mary, only child of the late Lieut. William Carr Hamond, Royal Engineers.

MORGAN—EDYVEAN.—On Aug. 13th, at the Parish Church, Bodmin, William Lewis Morgan, M.A., of Exeter College, Oxon., M.R.C.S., to Lucinda Mary, daughter of the late Major Edyvean, of Windsor House, Bodmin.

SMITH—NICHOLLS.—On Aug. 17th, at St. Stephen's, Coleman-street, E.C., by the Rev. M. Lambrick, Fredk. J. Smith, M.B., M.R.C.P., F.R.C.S., of West-street, Finsbury-circus, to Janet May (Sister Talbot), widow of the late George Henry Nicholls.

DEATHS.

HABERSHON.—On Aug. 22nd, at Brook-street, Grosvenor-square, W., Samuel Osborne Habershon, M.D., F.R.C.P., aged 64.

JOBSON.—On Aug. 23rd, at Bishop Auckland, John Jobson, F.R.C.S. Eng., J.P., county Dublin, aged 79.

MILLER.—On Aug. 27th, at Ettrick Tower, Merchiston, Edinburgh, after a week's illness, William Cornfoot Strettell Miller, M.D. Edin.

TOMKINS.—On Aug. 22nd, at Norwood House, Whiteladies-road, Clifton, Bristol, Charles Joseph Tomkins, M.R.C.S., L.S.A., eldest son of the late Charles Tomkins, M.D., of Abingdon, Berks, after six years' paralysis, aged 67.

WYLLIE.—On Aug. 24th, at Homburg, Surgeon-General David Wyllie, of the Bombay Army, aged 69.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE STUDENTS' NUMBER OF "THE LANCET" will be published on Saturday next, Sept. 7th. Those gentlemen holding official situations connected with medical institutions in the United Kingdom who have not yet forwarded the necessary information to our Office for publication in that number are earnestly requested to send it *without the delay of a single post.*

"FALLING FROM A HEIGHT."

ON this subject a correspondent writes to us as follows:—

"With reference to your annotation in THE LANCET of Aug. 24th, on the subject of falling from a height, you say the 'feelings of any who have made such perilous journeys will probably long remain matter of conjecture.' I beg to inform you before studying for the medical profession I was a sailor for some years, and on one occasion, when I was about seventeen years of age, I fell from the topgallant yard of an East Indiaman, a height, I should imagine, of at least 120 ft. During my transit through the air sensation was entirely lost; it slightly returned on striking the water, but by the time I rose to the surface I was able to strike out (being a good swimmer) and seize the life-buoy which was thrown me. I believe, had I struck a hard substance, death would have been painless; but the assertion that people die in the act of falling is evidently wrong. During my time at sea I witnessed two deaths by falling from aloft; in one case the man struck the rigging, bounded into the sea, and never again rose to the surface; in the other case the man fell on the deck, death being apparently instantaneous."

W. B. H.—"Alcohol is the devil in solution," the phrase of Dr. B. W. Richardson in a memorable exposition of the evils of excessive drinking, seems to have been anticipated by poor Alfred de Musset when he inscribed on his bottle of absinthe the line from Dante's "Inferno," "Per me si va nella città dolente" ("Through me the path into the city of woe.")

VOLUNTEER MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—Could any of your readers who have recently passed the proficiency examination for acting surgeons of the Volunteer force give me information as to the extent of the examination, and advise as to the best books to study?—I am, Sirs, yours faithfully,

August, 1889. ACTING SURGEON.

MALCOLM MORRIS INDEMNITY FUND.

THE following additional subscriptions to the above fund have been received:—Mr. Marcus Allen (Brighton), £1 1s.; Mr. Lovell (Deal), £1 1s.

"HEIL DIR, CARL THEODOR!"

UNDER this title ("Hail to thee, Charles Theodore!") we give a translation of the verses in which the eminent man of letters and poet, Oscar von Redwitz, congratulates His Royal Highness on the "fiftieth anniversary of his birthday." The "Duke-Doctor's" philanthropic work as an oculist and general consultant among the poor of the Bavarian and Austrian Tyrol we have already noticed, and von Redwitz's ode gives poetic form to the felicitations embodied by the peasantry of that lovely lake and hill country in bonfires and "feasts of lanterns." The translation reproduces the sense of the original as closely as a strict adherence to its double rhymes and metrical movement admits of:—

Five decades now have drifted
Since first beheld the light
A babe divinely-gifted,
To prove a "saviour knight."
How wise the life-revealer,
Who then and there could see
Bud forth the future healer
From that old warrior-tree!

Let courtier gossips prattle
Of some barbaric king,
Who from the field of battle
Could wreaths of laurel bring:
Far grander his achievement
Who toils among the poor;
The blind of their bereavement
With patient skill to cure.

Not his the work half-hearted
To while dull hours away;
On nobler errand started
He journeys through the day.
But first at matin service
He kneels in prayer, to ask
For grace of God to nerve his
Good genius to its task.

O all ye eyes, with lustre
And light by him endued,
Around, in starry muster,
Beam forth your gratitude!
All ye, who from his healing
Live longer, happier days,
Unite, with organ pealing,
Your voices in his praise!

"Heil dir!" from Tyrol's *châlet*
Floats down in choral chime;
"Heil dir!" from Tegern's valley
Beat all her waves in time.
And be your plaudits doubled
For her, his consort leal,
To whom the sick, the troubled,
Make never vain appeal.

While through the years ensuing
Thy name will be a word
For tender duty doing,
For light of life conferred;
If fulsome praise thou spurnest
As counterfeited ore,
Yet take, for once, this earnest
"Heil dir, Carl Theodor!"

"BITTEN BY A HYDROPHOBIC PATIENT."

To the Editors of THE LANCET.

SIRS,—In your issue of the 17th inst. is a small note, on page 348, with the above heading. The statements therein contained, that "the patient bit through the hand of the surgeon attending him so severely," &c., being quite unfounded, I hasten to state the simple facts of the case as follows:—A soldier suffering from hydrophobia was sent to the military hospital here, and the medical man in attendance on him injected subcutaneously some morphia with a Pravaz syringe. Upon his withdrawing the syringe he pricked himself with the needle, the point only raising the scarf skin. The surgeon went to the institute at Bucharest. He has since returned, and seems to have suffered more from the cauterisation &c. under which he went than from anything else. He is certainly now in the best of health and spirits. The soldier died after several days' severe suffering.—Yours faithfully,

A. IRWIN BOLTON, M.B., A.B.

Roumania, Kustendjie, Aug. 22nd, 1889.

To the Editors of THE LANCET.

SIRS,—In this week's LANCET there is an account of a doctor bitten by a hydrophobic patient, whose case is being watched with interest. I beg to state that while acting as clinical clerk for Dr. Langdon Down at the London Hospital, I, with Mr. Havens, the house-physician, had a severe struggle with a patient suffering from hydrophobia who died next day, in the course of which I was severely bitten in the thumb and through the palm of the hand. I went about in considerable dread until I learnt from Trousseau (*vide* Clinical Lectures, Sydenham Society) that hydrophobia was not communicable from man to man. What M. Pasteur has to say to this remark of Trousseau I do not know, but I am sure Trousseau would not have made the statement without good grounds. There is in the same paper an account of a man who died from hydrophobia without any bite. This is now the third well-authenticated case. One previously having occurred in Paris, one in the village of Putney, where it was seen by a number of medical men, all of whom had previous experience. I assisted at the post-mortem, and had previously seen three post-mortems of individuals dying from hydrophobia with similar appearances. In this case, an elderly woman who had not left her house for some long time, had an old dog with very foul teeth, which fed off the same plate; this dog was subsequently preserved until it died of a natural death some time after its mistress's decease from hydrophobia. These cases tally with a certain outbreak among an isolated herd of deer in Richmond Park, and all point to the possibility of a spontaneous or idiopathic form of hydrophobia, although it appears difficult to reconcile this with M. Pasteur's ideas on the subject; but facts are facts, and no doubt as further attention is paid to the subject more cases of spontaneous hydrophobia will be observed. For the present there have been at least three well-authenticated cases. I am, Sirs, yours faithfully,

Point House, Putney, S.W. ED. F. GRÜN, M.R.C.S., L.R.C.P.

TETANUS AFTER PARTURITION.

Dr. Benington, of Newcastle-upon-Tyne, asks to be allowed to refer Mr. Peacock and Mr. Cochrane, and others who may be interested in the above subject, to a paper written by him and published in the first volume of the Transactions of the British Gynæcological Society, 1885.

KERATOSIS.

G. B. W.—The disease is a rare one, and figures rather in treatises on teratology than in ordinary text-books. A remarkable case is that described by Joseph Hansard in his "History of the County and City of Waterford" (Dungarvan: 1870). Anne Jackson was born in Waterford city, of English parents, both of whom were sound in constitution and healthy. At three years of age horns began to grow on several parts of her body, till when about thirteen, her whole integument became so indurated that she could hardly move, and she was so stunted that five-year-old children were taller. On her knees and elbows and round the other joints horns projected—one on her arm being about four inches long and half an inch broad. She ate and drank heartily, slept well, and performed nature's offices like all healthy people. An analogous case of hypertrophy of the osseous tissue is recorded in Sir R. Christison's Memoirs, vol. i. It was operated on, but without success, by the great French surgeon Roux.

A Medical Student.—The plan of going to a colony without having obtained a qualification in the hope of getting a licence to practise is not at all a desirable one, and in Australia our correspondent would probably meet with disappointment. Many colonial universities might recognise his curriculum, but not the anatomical examination of one of the Irish colleges. The University of Otago would recognise the earlier M.B. examinations of Trinity College, Dublin, or the primary Fellowship of the English College of Surgeons. In New Brunswick and Nova Scotia an unqualified man can pass a qualifying examination, and in some portions of British territory—India, for example—any person may practise. In some of the Australian colonies there are numbers of unqualified men practising, but they are in much the same position as bonesetters are in this country.

Mr. Haynes Cory.—A notice of the instrument will appear shortly. Its merits are under observation.

Dr. McNeill (Lincoln).—We shall be pleased to receive the paper.

THE CÆSAREAN SECTION.

R. H. S.—Long before the historical advent of the Julian *gens*, the excision of the full-grown child from the gravid uterus was practised. Virgil (Æneid, X., 315), in describing the battle between the Latins and Trojans, says of Æneas: "Then he wounds Lichas, who had been cut out of the womb of his already dead mother, and was sacred to thee, Apollo." On this passage the commentator Servius writes: "All who are born by section of their mothers' womb are consecrated to Apollo as being the god of Medicine, through whom they are vouchsafed the light. In this way also Æsculapius was born. The family of the Cæsars, moreover, held in their keeping the sacred rites of Apollo, for the reason that the first of that family was brought forth by excision from the womb." See Dübner's edition of Virgil (Didot: Paris, 1858).

THE JONES FUND.

THE following additional sums have been received for the appeal made in our issue of July 20th to raise a sum to meet the legal expenses (over £60) of Mr. Jones of Edmonton:—Sums already acknowledged, £24 15*s.* 6*d.*; F. de Havilland Hall, M.D., £1 1*s.*; G. Henty, M.D., 10*s.* 6*d.*; W. H. Plaister, Esq., 10*s.* 6*d.* Further subscriptions will be gladly received by Dr. J. W. Hunt, 101, Queen's-road, Dalston, N.E. The list will close next week.

Astonished.—The action of Dr. B—— does not seem to show that dignified independence which is always desirable when a patient wishes to change his medical adviser. Some allowance may perhaps be made for feelings based on generations of professional attendance and possibly a conviction that the dismissal was not justified by any fault of which Dr. B—— was conscious.

Dr. Belcher (West Brighton).—The account, though interesting, lacks direct medical authentication, and is devoid of the details necessary to render it useful to professional readers.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. W. T. Gairdner, Glasgow; Dr. S. H. Habershon, London; Dr. A. E. Garrod, London; Mr. T. Bond, London; Dr. T. Hull Daily Mail, Weekly Free Press and Aberdeen Herald, Hertfordshire Mercury, Cork Examiner, Surrey Advertiser, Mining Journal, Madras Mail, Birkenhead and Cheshire Advertiser, Reading Mercury, Christian Commonwealth, City Press, &c., have been received.

Medical Diary for the ensuing Week.

Monday, September 2.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, daily at 10 A.M.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
ST. MARK'S HOSPITAL.—Operations, 2.30 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.

Tuesday, September 3.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same days, 2 P.M.

Wednesday, September 4.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M. Thursday & Saturday, same hour.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M.; Surgical Visits on Wednesday and Saturday at 9.15 A.M.

Thursday, September 5.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

Friday, September 6.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, September 7.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

SUBSCRIPTION.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 7, 1889.

ADDRESS TO MEDICAL STUDENTS.

TIME, ever restless, is once again bringing us face to face with the commencement of a new medical year, and is bringing with it also its batch of aspirants to the wand of ÆSCULAPIUS. Men are coming forward, for the most part filled with the energy of youth and prompted by hope, some feeling even already the deeper thrusts of the keen needle of ambition, which would lead them to strive for higher things even before the first rung of the ladder has been surmounted.

Students, taken as a whole, possess a certain *facies*, a particular generic likeness, which a careful observer can find stamped upon them almost from the first, and year after year this likeness is found reproduced with surprising similarity. The first-year's man, for instance, is easy to be recognised; his walk, his manner, his conversation, all these mark him out as a beginner to be shaped and evolved into the finished product—a cultivated medical man. Last year we dealt more particularly with the student in this his chrysalis stage; we intend now to follow him further in his course, and to refer somewhat in detail to those points the cultivation of which appears to us most surely to lead to the production of the best samples of the Galenic butterfly. In dealing with generalisations on this subject it is almost impossible to avoid repetition, and much that we shall have presently to say has been dilated on previously; still a good lesson does not spoil for being twice told.

The choice of the profession of medicine should be made only after the most careful consideration of its aims and requirements, and after a diligent endeavour on behalf of the would-be student to discover whether he is fitted, mentally and physically, to undertake the responsibilities of the calling. Some men enter the profession who, though they succeed in obtaining a qualification and manage to eke out a livelihood by its practice, are yet unfitted for the work. They may possess a physical organisation incapable of withstanding the arduous bodily labour which every country practitioner is called upon to perform; their voice may contain not a single chord the vibration of which brings comfort to the ear of the restless sufferer; a mind, untrained to methods of comparison and devoid of judicial balance, may constantly lead their judgment astray; or a manner, brusque and abrupt, may make them out of place in a sick room. To such men the earning of the honourable competency within the reach of all capable practitioners is a matter of the hardest toil, and they find absolutely no delight in the exercise of a calling utterly unsuited to their tastes. It remains for them only to regret that before the commencement of their training a kind friend had not pointed out to them their incompatibility with their chosen vocation.

It must be remembered—and it deserves from us especial emphasis—that a good medical practitioner, like a genius, requires in his composition much that is innate, much that cannot be supplied by education alone; and it behoves those on whose shoulders falls the responsible task of deciding "what we shall do with our sons" to endeavour to discover if the candidate for medicine is naturally fitted for practice. Mere capacity for remembering is not sufficient, nor is simple diligence or power of application. Probably one of the most essential things is a sympathetic temperament—just that very quality in which the medical student of olden days was supposed to be deficient. And another essential is tact, for more patients are lost to a practitioner through want of tact than through assumed want of skill; tact, and tact alone, will often cause the most obstreperous and self-willed minds to bend to the will of the physician and carry out faithfully a line of treatment personally found most disagreeable: a trusted practitioner has constantly placed before him problems of perhaps only semi-medical nature, which require the most delicate manipulation to bring to a satisfactory solution, and the handling of which will make great calls on his tactical qualities. Then, again, it need hardly be said that the successful medical man must possess a large fund of common sense, a most subtle mental compound hard to define and to isolate, but in its absence making the need of it most keenly felt. The presence of such qualities as these, never created but always improved by education, furnishes a groundwork, a substratum, which under cultivation becomes the mind of the talented physician. The early recognition of these qualities is not always an easy task, though sometimes they are clearly marked.

Let us now take it for granted that the preliminary examination has been passed and that the medical school is selected, and let us follow the student as he enters on his work. He will find himself confronted with a long curriculum, and he will discover that he is expected to master many separate branches of learning. "What are the best methods of learning?" is a question always asked by the tyro when he sees the formidable list of subjects before him, and the still more formidable size of the volumes which serve as text-books of each. He feels that no mere intellectual effort, without system and unguided, will enable him to master even a minimum of the information required nowadays from candidates at the examining boards. We repeat here what has been often said before: there is no royal road to knowledge, and the method which one student finds to give him the best results for his mental labour will be utterly unsuited to another.

One of the first things to be cultivated is a proper habit of thought. Let the student think out for himself the problems put to him, and let him seek to discover a reason for everything. The confidence engendered by such a practice is one of the healthiest stimuli to further study. When he begins, the disappointments will of course be many, and the explanation of facts seem even more complicated and obscure than their bare statement; but this feeling will speedily wear off, and the pleasure experienced in the possession of rational knowledge will more than repay the extra labour expended in its thorough acquisition; he will with pride find himself becoming converted from a laborious reader of books into a student in the truest sense of the term.

Lectures should be attended diligently for several reasons:

Digitized by Google

among others, because attendance on them is a duty required by the examining bodies, and every duty worth doing is worth doing well; because it is the business of a good lecturer to impress facts of importance which are easily overlooked by the casual reader; and because lectures serve to mark out the work of a session into regular stages, securing, if followed, diligence from the first, and preventing undue congestion towards the end. Notes at lectures should always be taken; the facts, the headings, recorded in brief, while the conclusions and the reasons leading up to them should be taken down more fully. There is no better mental exercise than the learning to make an intelligent abstract of this kind during the progress of a lecture; and to aid in the accomplishment of this sufficiently fully and satisfactorily stenography will be found most valuable. We believe the day to be not far hence when shorthand will be as commonly used in the class-rooms of a medical school as it is at a reporter's table.

It is an excellent plan to keep a separate note-book for each subject, and to write on one side only of the page, reserving the opposite for an abstract of a different kind, to be made after a diligent perusal of the lecture in the chosen text-book. These two abstracts standing side by side will be found invaluable as a means of impressing on the memory the subject matter to be learned; the one will be an epitome of the language of the lecturer, the other the concrete expression of the student's own cerebration on the subject, for the text-book abstract should never be copied direct, but should be compiled after the book is closed—it should be a true memory picture.

And this brings us to the subject of reading. Nearly every beginner is anxious to know how best to read. Here there is the greatest diversity. Some, not many, do their best work in the early morning; others prefer to labour before or after lunch; and others, again, reserve their energies for an evening spell. As to the attitude best to adopt in order to absorb knowledge, there is also wide divergency of opinion: one will sit bolt upright in a straight-backed chair; another will assume a position more nearly approaching the horizontal; while a few declare themselves incapable of doing good work unless they place themselves in a posture of partial inversion. As to the advisability of companionship, the same diversity still prevails: "reading in pairs" finds favour with many, the text-book being taken by each alternately and read aloud; others prefer to be left severely alone. With inanimate companionship, again, there is no common custom: those are to be found who, without the consolation of the fragrant weed, find thoughts flighty and attention unfixed; but once the calumet be lighted, then strings of "relations" and "equations" are eagerly garnered to the casket of the memory, fact following fact with the regular puff of the pipe, and ascending, like the smoke ring, to disappear in the intellectual firmament, but ready to be conjured up again by the wand of recollection. We would leave this portion of the subject with the statement of a few aphorisms: Good reading is not, as a rule, to be done at long stretches; read an hour and rest ten minutes, thinking carefully over the matter read; waste no time by copying long extracts from authors where the original is ever at hand in more legible form; mark particularly those paragraphs containing explanations and reasons, and those often given in the form of recapitulations; and finally, as above advised, when the section is ended, leave time sufficient to shape out a concise epitome for the note-book.
